I thought for a day or two that it was only the worms that produced the convulsions, but I noticed the conjunctivæ were of a yellowish-green color, and the child could not see well. After a few days the eyesight got all right.

The second cases were in the year following, 1881. Two children in one family were treated for worms by the mother, under some directions from their family physician. On the third morning I was called to see the children, "with fits," as they called them. Stimulants internally, heat to the extremities, a copious enema, and such measures as were calculated to keep up the circulation, were used.

The kidneys were secreting but little urine. The pupils were dilated.

After some hours' work the bowels moved and kidneys acted well, and the children got up, but no worms were passed.

The drug had been given in these cases in conjunction with calomel and sugar. I do not know in what amounts.

The next case was a little boy, 7 or 8 years old. He was taken ill during my absence, and another physician was called to see him, and he gave calomel and santonin. Three doses, 3 grains of the latter to 4 or 5 of the former.

The bowels never moved for forty-eight hours, and as soon as I arrived home I was called to see the little fellow. His limbs were flexed, bathed in cold sweat, pulse 150 to 160, respirations jerking, pupils dilated, jaws set, abdomen swollen, and comatose nearly all the time. I could do but little. Stimulants rubbed on the spine, plenty of warm water and soap enemas, poultices to the abdomen, blister to the nape of the neck, etc. After a while the bowels moved copiously; green offensive matter.

At the end of five hours he could talk, move, and swallow water. The urine was very scanty and high-colored. By the use of diuretics his kidneys assumed their normal functions.

I was indeed very much puzzled over this case until I found that the child was very nearly blind for over a week. Everything was yellow

to him for some ten days. Having seen in the "National Dispensary" that blindness had been produced by santonin, I could better account for the great disturbance.

I have seen many other cases that were similar to the above, but not so severe.

I find it will not do to give santonin to children while they have high fevers, or when the bowels are costive. If given with castor oil and sugar mixed together it does much better.

I have little doubt but that through the indiscriminate use of the drug by parents and physicians many children are killed by its effects.

I would be pleased to see the reports of other physicians on this drug. If we have bad results, let us report them as well or more so than our good success, for by so doing we will benefit mankind.

Very truly yours,

CHEVES BEVILL, M.D.

WINFIELD, ARK.

CUTANEOUS DISORDERS FROM INDIGESTION.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In your reply to my query in the March number of the GAZETTE, page 212, you call the disease to which I referred *urticaria*, and so headed my article for me. I think likely I did not make myself well understood, as you missed the mark in the heading, and also failed to answer the particular point about which I was wanting information. I quote my language: "Now, what I want to know is, why this disturbance of the stomach is telegraphed by the nervous system to this distant locality and nowhere else?" I fully endorse your remarks on *urticaria*, as also those of Dr. H. D. Thomason in the April number of the THERAPEUTIC GAZETTE. The subject of my query has none of the characteristics of *urticaria*; none of that heat with burning and stinging sensation, giving it that significant name, nettle-rash; none of those nodulated or elevated wheals or patches; nothing visible to the naked eye, however much rubbed or scratched, and it is confined to the legs; sometimes in spots, and sometimes extending over the whole surface from the knee- to the ankle-joints. And I said at middle age, but I will add at any period of life beyond this. I have never heard a woman complain of it, while they frequently consult me about nettle-rash; and I agree with Dr. Thomason that, according to my ob-

servation, they are more frequently troubled with it than men, and I think there are obvious reasons why they should be. If I were going to name the subject of my query I would call it "Pruritus senilis," but I am no stickler for a name. I thus hastily write the above explanation for insertion in the *GAZETTE* because I think I was misunderstood by you, and by your reply to my query Dr. Thomason was misled, as would be all other readers of your valuable journal.

R. L. HINTON, M.D.

PRESCOTT, NEVADA CO., ARK.

[The case described by Dr. Hinton would rather come under the name of pruritus than urticaria, as we meant to indicate in our comments on the article. The method of production of the eruption, in our opinion, is precisely the same as in gastric urticaria, and we supplied the title of "urticaria from indigestion" as representing the most familiar example of eruptions so produced.—Eds.]

THE NEW TREATMENT OF PHTHISIS.

To the Editors of the *THERAPEUTIC GAZETTE*:

GENTLEMEN:—In an article in the *GAZETTE* for April 15, Dr. Wood refers to the difficulty with Bergeon's method of treatment of phthisis in private practice, in the cumbersome of the apparatus and the skilled labor required for the preparation of the gas.

It seems to me that these objections are obviated in the following described plan, which was devised and has been in use by myself for several weeks: A so-called soda-water bottle is charged at the factory with carbon dioxide, connected by a rubber tube with a Wolff-bottle partially filled with water saturated with pure hydrogen sulphide, and the Wolff-bottle again connected with a rubber bag having a stopcock. Pressing gently upon the lever of the soda-water bottle, the carbonic gas is forced through the sulphurous water, carrying the combined gas into the bag. When the bag is filled the stopcock is turned, a rectal nozzle is introduced, and the bag carried to your patient all ready for treatment.

My patients send for these bags and administer the gas to themselves after two or three lessons. Knowing the size of the bags, you can regulate the amount of gas used at each séance. The sulphurous water should be renewed after being used to fill a three- or four-quart bag two or three times. At ordinary temperatures the carbonic gas will take

up sufficient hydrogen sulphide in a bulk of three or four quarts of the combined gases for its safe use.

A decided collapse was caused in one of my cases by using six quarts of the gas as made above. My patients taste the sulphur soon after its administration, and continue to do so for hours. In about forty administrations it has been rejected but once. After introducing the rectal tube I press gently upon the bag, and after a minute or two the gas will pass in rapidly, causing a little colic; then I turn off the stopcock and wait a minute or two and turn on again.

This treatment has a marked effect in relieving the septic phenomena, chest-pains, dyspnoea, and diarrhoea. The sputa lessens in amount, becomes thinned and yellowish in color.

Again as to the apparatus, should there not be a soda-water manufactory at hand the carbonic gas can readily be generated and stored as proposed in a large rubber bag, and from this forced through the sulphur-water into the visiting-bag as required. The sulphur-water may be prepared by the druggist or the physician at his leisure, or the druggist himself may fill the administering- or visiting-bag upon prescription. Will not this plan meet the objections of cumbersomeness and the necessity of skilled labor at the bedside?

BYRON H. DAGGETT, M.D.

258 FRANKLIN STREET, BUFFALO, April 30.

GELSEMIUM AS AN ANTIDOTE TO OPIUM-NARCOSIS.

To the Editors of the *THERAPEUTIC GAZETTE*:

GENTLEMEN:—From the known physiological effects of gelsemium and my own experience in its administration, I came to the conclusion that it would prove an antidote to the lethal effects of opium, but had no opportunity of testing its qualities in this respect until July 26, 1885, when I was hastily called to see Mr. Frank C., a young man residing about two miles from this city, who had about two hours previously swallowed an ounce of laudanum with suicidal intent. I found him profoundly comatose, pupils contracted to a pin's point in size, face turgid and dusky red, carotids pulsating violently, so much so as to jar his head, respiration slow, etc. Having no stomach-pump, and not feeling safe in using apomorphine in his condition, I titillated his fauces, placed 2 scruples pulv. ipecac between gums, lips, and cheeks, gave him the bastinado, castigated bare legs and rump with

a handful of switches to near vesication without results. Stertor becoming more profound, I determined to test the virtues of gelsemium, and gave hypodermically 25 minims of the fluid extract. I repeated the dose every twenty minutes until one hundred minims had been given, when I paused, fearing to administer for the present more of this powerful remedy. I observed, however, when the second dose was given, that the carotids were acting with less force, and between one and two hours from the first dose the action of the carotids grew calm and dusky color of face markedly less. I now resorted to "masterly inactivity," and carefully watched my patient for near an hour; then his respiration became spasmodic and alarming. I immediately administered subcutaneously $\frac{1}{4}$ gr. sulph. strychnine in solution. Respiration soon became normal, and in view of all the features of the case I ventured another hypodermic injection of 15 minims gelsemium. Soon afterwards, perhaps thirty minutes, the patient became conscious, opened his eyes, and recognized every one present. His first desire was to urinate, and he passed an inordinate quantity. Thus in rather less than three and a half hours the patient had received subcutaneously one hundred and fifteen minims fluid extract gelsemium. Being now perfectly rational and able to sit up in bed, I left at 9.30 P.M., after giving nurses strict orders to keep him awake, walk him, etc., until 5 A.M. While walking in the yard the ipecac had its effect, producing full emesis, the ejected matters exhaling the odor of laudanum. Next morning's visit, 9 A.M., found the patient all right, but "feeling very sore."

W. D. HUTCHINGS, M.D.

MADISON, IND.

THE THERAPEUTIC PROPERTIES OF CORN-SILK.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—During the last three years, or ever since the introduction of corn silk as a remedy, I have had ample opportunity to test its therapeutic effects in those diseases for which it is recommended. I have no new qualities of this drug discovered, but merely desire to corroborate the statement of other physicians, who speak in favor of this remedy. My experience with the fluid extract of corn silk has been most satisfactory in every respect, having used it in many different forms

of acute and chronic diseases of the kidneys and bladder, and I find it a valuable remedy in these ailments. In all catarrhal disorders of the genito-urinary organs I find it superior to other medicaments I formerly tried. I have used it in retention and suppression of urine in adults and infants with the best success. In the acute stage of gonorrhoea, alternated with alkalies, it will relieve the scalding in passing water, allay pain, and shorten the first stage. In organic heart-disease, when there is deficiency of urine, it will act as a mild but certain diuretic, increasing the flow of urine when other stimulating diuretics have failed to produce diuresis. The fluid extract of corn silk, given in drachm doses, will also relieve the periodical attacks of dyspnoea in this trouble, and, alternated with 15 drops of the fluid extract of *cereus bonplandi*, I consider these two remedies as excellent palliatives in functional as well as organic ailment of the heart, believing that, besides its demulcent and diuretic actions, corn silk has considerable anodyne properties.

In regard to dosage, I found that in acute renal diseases, or in retention or suppression of urine, where a decided action is required, full doses—1 to 2 drachms of the fluid extract, well diluted with water—may be given, repeated every two or three hours until the desired result is obtained. In chronic cases, 20 minims to $\frac{1}{2}$ drachm, four times daily, in a wineglassful of water, an hour before meals, acts best. It may be given for weeks or months without deranging digestion, but the doses will have to be increased if given for any length of time. Therefore it is well, after giving the corn silk for two or three weeks in chronic renal cases, to alternate with other mild diuretics, such as buchu and acetate potassæ. Notwithstanding the fact that corn silk is an excellent remedy in irritable bladder when given in small doses, it will, when exhibited in large or overdoses, to a healthy person or in subacute cases, cause irritability of the bladder, palpitation, and restlessness; but these symptoms are easily relieved by some effervescent draught, such as citrate or bromide potassium.

If the preparation of corn silk has not been successful in the hands of some physicians, they very likely used an inferior article, as I myself was disappointed in its action when I prepared a saturated tincture from the green corn silk, or was furnished by my druggist with some weak preparation.

Notes and Queries.

NOTE ON TWO ANTIPYRETICS.

I.—ANTITHERMIN.

Under this name M. NICOT publishes in the *Nouv. Remèdes*, 1887, 102, a new antipyretic, phenylhydrazin,—levulinic acid,—which is, chemically, closely related to antipyrin.

Commencing with phenylhydrazin, $\text{C}_6\text{H}_5 - \text{NH} - \text{NH}_2$, we may state that this body shows, almost more than any other that is to be met with in modern chemistry, the greatest reactive powers. Thus it has the quality of combining with aldehydes, ketone sugars, and forming with them perfectly well characterized and crystallized compounds. It shows the same properties also with regard to ketone acid and its ether. For instance, it combines with acetoacetic ether to the basis called monomethylchinizin, of which antipyrin is a methyl compound.

To the substances which combine with phenylhydrazin *levulinic acid*, $\text{C}_6\text{H}_5\text{O}_4$, belongs. This latter is obtained by applying dilute acid to levulose.

The mode of preparation of antithermin is as follows: Phenylhydrazin is dissolved in dilute acetic acid; on a solution of levulinic acid being added a yellow precipitate is formed, which, by means of crystallization from an alcoholic solution, produces well-formed crystals of phenylhydrazin-levulinic acid of the above-mentioned constitution, and possessed, as is affirmed, of antipyretic powers.

Regarding the dose to be administered, manner of application, and clinical experience, nothing is as yet known.

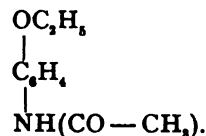

II.—ACETPHENETIDIN.

This is a German discovery. MESSRS. O. HINSBERG and A. KAST announce in the *Centralblatt f. d. Med. Wissenschaft*, 1887, No. 9, that *p*-acetphenetidin is possessed of considerable antithermic properties, as shown by a series of experiments (*Pharm. Zeit. Berlin.*, March 26, 1887). They gave doses of 3 to 8 grains, and were able in this manner to reduce the temperature of the human body on an average by 2°C . without any unpleasant secondary effects.

The preparation consists of colorless needles, which are soluble in water, still more so in alcohol and glacial acetic acid, and are devoid of taste. Their melting-point is 135°Celsius .

From these first communications it was not quite clear which chemical body was meant by acetphenetidin, it being also spoken of by others as "ascetphenidin," but since then the manufacturers have explained that acetphenetidin is the acetyl derivative of phenetidin,—that is, of the ethylether of paramidophenol.

The formula is

It is obtained from carbolic acid by the process of nitriting, separation of the artho- and para-nitrophenols, acetylating the latter, reducing the *p*-nitrophenol to *p*-amidophenol, which is called phenetidin, and acetylating the phenetidin with glacial acetic acid.

Antithermin and acetphenetidin are, therefore, now added to antifebrin, salol, chinolin, kairin, antipyrin, and thallin, the half-dozen of the newest and best-known antipyretics.

Antipyrin and antifebrin have indeed proved very formidable rivals of quinine, which, however, retains after all the first place among febrifuges.

Antithermin possesses, at least, a very promising name, which in any case is of some worth.

Acetphenetidin has not yet received an abbreviated appellation. Perhaps "anticalorin" would sound well, although by no means correctly chosen. Why have none of the discoverers thought of calling a preparation "antiquinine"? for this search after new antipyretics is surely more often aimed at rivalling quinine than anything else. Concerning these latest productions of the antiquinine movement we must as yet await further tests and proofs.—*Pharmaceutical Record*, May 1, 1887.

IODOFORM AND CALOMEL.

An incompatibility observed in a mixture of iodoform and calomel has been investigated by Mr. DRESCHER with a view to ascertain the chemical change that takes place. Equal parts by weight of the two substances, when triturated together in a porcelain mortar, manifested no change of color, nor was there any noticeable reaction or foreign odor. Some of the powder, when placed in a white vial, well corked and exposed to direct sunlight, showed at the end of one hour signs of decomposition. After five hours the powder exhibited all phases of color from whitish to yellow, with numerous greenish and grayish specks. There

was also at the top some bright orange-red powder, which proved to be mercuric iodide. Another portion placed in an amber-colored vial and exposed to direct sunlight, behaved somewhat similarly, except that the decomposition took about three times as long. A third portion, placed in an amber-colored bottle and exposed to diffused light, showed no signs of decomposition at the end of one week, but after two weeks change was quite evident. Some of the powdered mixture, gently heated in a test-tube, gave off the odor of chloroform, especially when the iodoform and calomel were used in proportional quantities, and there was a formation of mercurous iodide, which, upon the temperature being raised, was converted into mercuric iodide. The reaction supposed to have taken place is—

AN ANTISEPTIC FLUID FOR USE ABOUT THE EYE.

GRANDMONT reports a case of occluded lachrymal duct, in which he opened the duct and disinfected it with the following fluid :

Chloral. hydrat.,
Sodii salicylat., aa gr. viii;
Aque, ʒi.

—*Les Nouveaux Remèdes*, No. 8.

GASEOUS RECTAL MEDICATION IN PHTHISIS.

A fresh series of observations by M. PERRET appears to result in conclusions in general harmony with other recent trials of the method. He states that the gaseous injections have no microbicidal action; they can modify the bronchial phenomena and diminish expectoration, also influence nutrition for good, especially in the apyretic forms, like other medicaments, and hence are of value in relieving particular symptoms. The outcome of this appears to be that they are as good as, but no better than, other bronchial remedies.—*The Lancet*, May 28, 1887.

THE TREATMENT OF MORPHINOMANIA.

DRS. JONES and BALL have recently published an essay on the treatment of morphinomania, in which they state that they relied chiefly for the cure of these patients on nitroglycerin and sulphate of sparteine. Nitro-

glycerin may be administered as a one per cent. alcohol solution, while the sparteine is to be administered hypodermically in doses of from one to four centigrammes.

SO GERMAN, YOU KNOW.

["And I saw many strange things in heaven."—ST. JOHN.]

We speak of a coccus as causing the gleet,

For that is quite German, you know;

Iodoform use, since its smell is so sweet,

For that is quite German, you know.

We dilate the rectum with hydrogen gas

To kill the bacilli that through the lungs pass,

Then put our poor patient down under the grass,

For that is so German, you know.

A man may be shot in a glorious cause,

For that is quite German, you know;

We extract the bullet and wrap him in gauze,

For that is quite German, you know.

With carbolic acid we sozzle the wound

Until the poor fellow is up and around,

Or maybe is dead and put under the ground,

For that is so German, you know.

The comma-bacillus (we think so at least),

For that is quite German, you know,

Slips through a man's bowels as if it were greased,

For that is quite German, you know;

We use "antiseptics" to check the discharge

(The rate of mortality still is as large),

And next disinfect his grave free of all charge,

For that is so German, you know.

We'll find that bacteria hasten divorce,

For that is quite German, you know;

"Spirilli of homicide" follow, of course,

For that is quite German, you know.

A "microbe of lying" will be on the tongue,

And "melon-thief vibrio" found in the young,

The "germ of strong drink" will be seen at the bung,

For that is so German, you know!

At last when in Satan's hot home we will be

(For that is quite German, you know),

We'll use *sulphur vapors* to kill bacilli,

For that is quite German, you know.

Or if we to heaven instead emigrate,

Our harps, ere we use 'em, we will fumigate,

Our wings "sterilize" as we pass thro' the gate,

For that is so German, you know.

*HYGIENIC THERAPEUTICS—A LECTURE ON THE METHODS AND APPLICATIONS OF KINESITHERAPY.**

BY PROFESSOR DUJARDIN-BEAUMETZ, Paris, France.

GENTLEMEN:—In the last lecture we had under consideration the physiological effects which may be obtained from exercise and from movements. It now remains to see how far these physiological effects may be utilized in the treatment of diseases. But before undertaking this part of our subject,

* From advance sheets. Abstract of two lectures delivered in Cochin Hospital.

which is one of special interest, it seems to me desirable to explain, as briefly as possible, the procedures which may be put in usage to obtain these benefits; in other words, to set forth the methods of gymnastics.

When you take a general survey of these methods, you see that they may all be ranged in three categories. Some are performed without apparatus; others require the effective co-operation of a master,—this is Swedish gymnastics; others still demand the use of apparatus, whether fixed or free, or characterized by automatic movements.

Gymnastics without apparatus are divisible into two great groups,—home gymnastics,†

† Gymnastique de chambre.

whose object is the promotion of suppleness of the frame, and gymnastics which belong to the natural exercises, such as the various attitudes, walking, leaping, etc.

The first kind, or home gymnastics, is of special utility in therapeutics. It consists in making different parts of the body, and particularly the limbs, execute numerous movements, which may be of great variety, and combined in a thousand ways. You will find in all the manuals of gymnastics, and, in particular, in the official manual published under the direction of the Minister of Public Instruction, a description of all these movements which constitute "elementary gymnastics," and which comprehend movements tending to give suppleness to the head, trunk, arms, and legs, and to the arms and legs together.

Schreiber has much insisted on this kind of gymnastics, and his works have had a great popularity in Germany, where his treatise on "Medical and Hygienic Home Gymnastics" has passed through fifteen editions. In the method of Schreiber the head and limbs are made to execute movements of circumduction more or less rapid. It has been said that these exercises, while giving good results, cannot take the place of gymnastics properly so called, because that in these simple "home" movements, whose object is to confer suppleness, the individual has no resistance to overcome, and the exercise involves no muscular labor. I cannot agree with this view. All movement demands muscular labor, and it is easy to understand that by these movements, which are so effective in giving pliancy, one may put in play almost all the muscular groups of the economy. Moreover, these home gymnastics have this advantage, that they can be performed in all places, in one's own room, almost without a teacher, and in accordance with the simple indications furnished by the physician.

Before taking up the study of natural exercises, such as walking, leaping, I must give you a definition of the words *position* and *attitude*. Position is compatible with a certain muscular relaxation, while attitude always demands some amount of muscular activity. Thus, standing is an attitude, while sitting and lying are positions. Every gymnastic movement, to have a determinate end, presupposes an initial and terminal attitude.

Walking is one of the most useful of gymnastic exercises. Marey, in his work, the fruit of his studies carried on at the physiological station of Parc des Princes, has laid down some excellent indications concerning

certain points in walking. He has shown us that the quickness of one's gait increases in proportion as one diminishes the height of the heel of his boots. He has also shown us that when the sole of the boot exceeds the length of the foot by a certain figure, the paces are lengthened, and he has fixed at fifteen millimetres, this figure by which the sole ought to extend beyond the great toe. Lastly, he has shown us that when one walks with a rhythm of from sixty to eighty steps per minute, the length of those steps is increased.

In the case of infantry when on the march this walking rhythm is higher, the steps being quickened to one hundred and fifteen per minute. It has been affirmed that a man may walk eight kilometres and four hundred and fifty metres per hour. This estimate seems to me exaggerated, and I am more inclined to accept that furnished by Michel Levy, who maintains that an adult man in good health may, without overtaxing himself, walk ninety metres per minute, which would give five kilometres and four hundred metres per hour, and he ought to be able to keep this up for six hours.

We distinguish three rhythms in running, according to the number of steps taken per minute. In moderate running one hundred and forty are made; in rapid running, two hundred; some racers make as many as two hundred and forty. When you prescribe running exercises to your patients remember to enjoin that these running exercises shall be short, and intercalated between an initial and terminal walking exercise.

I have nothing in particular to say relative to leaping and dancing, and I come now to the second division of gymnastic exercises in general, those that are made with the assistance of a master, and constitute SWEDISH GYMNASTICS.

Swedish gymnastics consist in provoking the voluntary contraction of certain muscles, while the assistant opposes with the hand a certain amount of resistance. Here, then, the presence of a second party is indispensable in guiding or opposing the movements which are executed. Meding* has divided these movements into semi-passive and semi-active movements. In the first, the movements are performed with resistance on the part of the subject; in the second, with resistance on the part of the master.

You easily understand how, by combining in a thousand ways these double and syner-

* Meding, "On Medical Gymnastics." Paris, 1882.

getic movements, one may succeed in developing all the muscular groups of the economy ; at the same time it is plain that this mode must always be limited in its applications, as each pupil or patient requires a gymnastic professor. It has, therefore, been abandoned for the most part in France as a part of general gymnastics ; while, on the other hand, it is coming more and more into use as a mode of medical gymnastics, for it enables us to limit the gymnastic action to a particular muscular group ; and Schenström,* who has been the chief promoter of Swedish gymnastics in Paris, has shown us all the advantages which may be obtained from these special exercises in a great number of affections.

Gymnastics with apparatus comprise a great number of varieties. Sometimes the apparatus is fixed, sometimes it is movable, sometimes elastic, sometimes moved automatically. At the head of gymnastics with apparatus I would place that kind of gymnastics which Pichery, who is the originator, has styled "*opposition gymnastics*," of which you may see numerous applications in our wards.†

Struck by the advantages which the method of Ling gives, Pichery conceived the idea of rendering this method of general applicability, by substituting for the professor who opposes the movements of the pupil a sort of *parlor gymnasticon*, with elastic cords and well-padded rings for the extremities, which tend to force back the members making traction to their original position. You readily see how easy it is to vary the different tractions made on these elastic cords, so as to put in play almost all the muscular groups of the economy.

These "opposition gymnastics" have the advantage of taking up little room and of being available anywhere. The apparatus can even be adapted to the bed of the patient, so as to enable him, although bedridden, to execute movements of the different members, and obtain all the exercise which his condition permits.

These "opposition gymnastics," then, constitute an excellent kind of medical gymnastics, which we can utilize in our hospital wards, and in some cases on a large scale, as you can see in the use which I have made of them in our female wards.

The gymnastic apparatus with pulley-weights is very much like those above described as "opposition gymnastics." Triat

has constructed a very ingenious sort of cabinet, containing a series of weights, which are put in movement by means of elastic bands with handles, and the apparatus is arranged so as to exercise the different parts of the body. This apparatus is very useful for the purpose of home gymnastics, but is rather too high-priced and takes up too much room to be of general use.

You will not expect me to give a description of all the paraphernalia used in gymnastics, and which you will find described in the technical treatises on gymnastics. The most useful are the upright bars, or chest-bars, which render the shoulder-joints supple and expand the chest, the leg-weights to be used while in a sitting posture, the pulley-weights, which strengthen the arms and shoulders, the dumb-bells, the clubs, the swinging-rings, the horizontal bars, the inclined ladders which are climbed with the hands, the vaulting-horses, etc. There is an infinitude of these apparatuses designed to give variety to the exercises and render them more attractive, all of which you can see in any of our Paris gymnasia.

Lastly, I must not omit to mention that sort of mechanical gymnastic apparatus which goes by steam, and is the invention of Zander, of Stockholm. Many of you must have seen a number of these gymnastic machines at the Paris Exposition in 1879, in the Palace of Industry. There was, indeed, a large gymnasium building erected on Chaussée-d'Antin Street expressly for this kind of gymnastics, but it was soon closed for want of patronage, so little enthusiasm have we Frenchmen for these exercises.

Zander, in his method, had taken the Swedish system for his model, substituting for the "professor" certain automatic apparatuses endowed with variable movements. There are appliances for giving motion to the knees, others for giving a movement of rotation to the shoulder, others, still more complicated, for imparting a suppleness to the trunk. In a word, there are parts of the apparatus adapted for producing a multiplicity of movements, and bringing into play all the muscles. Some of these movements are active, some are passive.

This species of gymnastics, which bespeaks on the part of the founder much hard work and great ingenuity, is very popular in Stockholm, where it is applied to medical uses. Thousands of patients every year flock to that city for gymnastic treatment in the great establishment which Zander has built.

* Schenström, "Reflections on Physical Exercises and Bodily Movements." Paris, 1880.

† Pichery, "Gymnastique de l'Opposant," etc. Paris, 1871.

You will see, as we go on, that this kind of mechanical gymnastics has been applied to diseases of the heart, and Zander, Nycander, and a large number of German and Swedish physicians affirm that they can thereby cure these affections, at least in their initial period. I shall have to allude to this subject farther on.

Thus far we have considered gymnastics in their application singly to the treatment of diseases or to the development of the body. Ordinarily, however, they are associated with other hygienic means, such as massage, hydrotherapy, balneotherapy, and dieting. The aggregate of all these means, when they are directed towards a special end, bears the name of *training*, and just as in zootechnics we see man, by the application of these means to the equine race, create varieties of animals fit for such and such uses, and in particular for the race-courses, so also we may by a similar kind of training put individuals in the best possible conditions to attain a given end. Thus it is that we have precepts of training for the boxer, for the pugilist, which Bouchardat has so well studied, for the various exercises of sport, foot- and horse-racing, steeple-chase, rowing, etc.

Training, which, in the case of horses, is but the gradual application of gymnastics in the most ancient and best known sense of the word, comprehends in man, besides the employment of graduated gymnastic exercises, a series of means which Bouchardat has classed under the seven following heads: 1. Evacuants; 2. Alimentation; 3. Care of the skin; 4. Pure air; 5. Moral influence; 6. Abstinence from venery; 7. Temperance.

The end to be obtained by putting in usage all these hygienic and therapeutic means is the following: To eliminate the liquids and solids which have become vitiated or detrimental to the harmony of the functions; to impress a new activity on nutrition; and to favor the development of organs towards a given end. Let us rapidly examine these different points.

As for purgatives, all trainers give them a place in their method. Bouchardat protests against this practice, and urges the suppression of drugs from this aggregate of hygienic means. You will see that when we come to apply training to the cure of certain affections, and in particular of obesity, we shall have to have recourse to the purgative treatment, which, moreover, is really indicated. Recall to your minds what I said in my first lecture concerning the physiological effects of

exercise. I showed you that exercise augments the production of leucomaines, and as the most important channels for the excretion of these toxic alkaloids are the intestine and the kidney, you understand the utility of promoting the functions of both these emunctories. One of these indications is fulfilled by purgatives.

As for diet, trainers recommend little drink and a dry diet. You remember that I had something to say about this subject last year.

The end of this dry diet is to diminish, as much as possible, the weight of the intestinal mass, which is a dead and useless weight. In the horse, this system of dieting, which consists in giving nutritious azotized aliments in little bulk and but little drink, has for its effect to give these animals the *greyhound stomach* which characterizes them.

Trainers then recommend their subjects to eat the dark meats, such as beef, mutton, and game; they suppress the white meats, starches, and fats. Bouchardat does not approve of this proscription, and if he favors the exclusion from training diet of starchy substances, he insists upon the free use of fats, which seem to him essential.

The care of the skin plays a considerable part in the training, whether of man or of animals. In the latter, grooming, according to Sanson, has a quite special action. It promotes reflexly the vaso-motor circulation of the different viscera; and you cannot fail to have noticed the carefulness and the patience with which race-horses are rubbed and curried. In man the same practices ought to be put in usage, and it is a good plan after the sweats to which the subject under training is subjected, to give him a brisk and thorough rub down with a flesh-brush and with flannel, and to follow these frictions by massage with the hand well oiled with vaseline.

It is taken for granted that hydrotherapy plays a considerable rôle in the means put in use to promote actively the cutaneous functions, and I shall return to this topic in the lecture which I propose to devote to this hygienic agency.

I need but allude to the necessity of pure air, which is a very useful adjuvant, facilitating, as it does, the combustions of the economy; nor shall I stop to comment on moral influences, which always depress the organism when they are excessive; nor on venereal abuses, which have the same effect; nor on the necessity of temperance, which, unfortunately, is the part of training which is, as a rule, observed the least, especially among

the English. It is, in fact, a common thing to see the English jockeys and boxers give themselves to alcoholic abuses.

Such are the various phases of training, and you will see that the precepts here given, when applied to the treatment of a great number of diseases, and especially to polysarcia and diabetes, are attended with remarkable results. I have now completed the description of the great methods of gymnastics, and pass on to the application of these methods to the treatment of diseases.

THE APPLICATIONS OF KINESITHERAPY.

We have seen that gymnastics modify respiration, circulation, innervation, digestion, and nutrition. We will now consider the benefits which may be derived from the methodical application of gymnastics in the different diseases of the systems and organs which subserve these functions.

Respiration plays a preponderant rôle in gymnastics, and it was Dally who thirty years ago said that respiration was the pivot of every gymnastic exercise. Authorities have even founded an aggregate of exercises to which has been given the name of respiratory gymnastics.

Dally recommends inspiration by the nose and expiration by the mouth.

Guye, of Amsterdam, maintains that both parts of respiration should be performed by the nose, and that neither inspiration nor expiration should be performed by the mouth. He considers respiration by the mouth as extremely injurious, and quotes with approval the saying of the American traveller, Catlin,—"If you will breathe with your mouth shut, you will prolong your life." Guye even insists that children should be habituated from infancy to breathing through the nose, though this necessitates closing the mouth by a special chin-piece, such as Delstanche has devised.

All this goes to show that there is nothing new under the sun, since it recalls to one's mind the method of Demosthenes, who used to put pebbles in his mouth and walk rapidly, thus carrying out the principles so many centuries afterwards laid down by Guye and Delstanche. Foreign bodies in the mouth prevent respiration by the buccal cavity, and compel respiration by the nose. Demosthenes, in adopting this practice, may not have improved his manner of speaking, but he certainly would augment his respiratory capacity in forming the habit of taking full breaths, which constitutes for the orator as well as

for the singer a point of the greatest importance.

In the previous lecture I told you that among the methods of gymnastics singing and chanting have a prominent place, and that a great many professors of gymnastics insist on the necessity of concert-singing while the pupils perform their exercises.

Dally, in his special treatise "On the Methodical Exercise of Respiration," has well described the different movements applicable to respiratory gymnastics. These exercises are four in number.*

In the performance of the first exercise, Dally places the patient in a vertical attitude, with the back against a wall, then both arms and hands being extended horizontally in front, the patient forcibly and slowly separates the fingers while he bends the thorax forward; he remains in this position thirty seconds, makes a deep nasal inspiration, and resumes the initial position, then makes a deep expiration, and repeats this exercise six times in succession.

In the second exercise the arms are dropped by the side of the body, then brought forward, the fingers on the stretch, and slowly raised to a vertical position above the head with the palms down, then brought back in front, when a deep inspiration is taken. The arms are then slowly let fall upon the sides of the trunk, with the palms upward.

The third exercise consists in executing with the arms two double lateral circles, from behind forward, from below upward; the circles should be made with a full sweep, and care should be taken to bend the body forward every time that the arms are thrown backward, and never to hit the loins. This movement ought to take place almost entirely in the scapulo-humeral articulations. Inspiration whenever the arm is raised, expiration when it is lowered.

The fourth exercise consists in alternate flexion and extension of the trunk, the arms being crossed.

But there is another and simpler exercise which will render you much service in developing respiratory capacity, viz.: to make the patient count with a loud voice as long as he can do so without losing his breath. Before commencing to count, the patient should make a deep nasal inspiration. You can even

* Dally, "On the Methodical Exercise of Respiration in its Relations to Gymnastic Conformation and the Health in General." (*Bull. de Thér.*, 1881, t. ci. p. 197.)

by the aid of this process calculate the respiratory capacity of the chest, for with the ordinary thoracic capacity one ought to count as far as fifty or sixty without losing breath.

I do not here need to describe the different types of respiration; they are, as you know, of three kinds: the abdominal type, due to the fall of the diaphragm; the costo-inferior type, produced by the elevation of the inferior ribs, which project anteriorly beyond the xiphoid appendix; the costo-superior or clavicular type, due to the rising of the clavicle. According to Dally, the largest quantity of air which can be made to penetrate the lungs is obtained by the nasal costo-superior inspiration; he recommends also to contract the abdominal muscles at this period of respiration. Respiratory gymnastic exercises, in augmenting the force of expiration, attain the same results.

Such respiratory gymnastics will render you great service in all diseases where there is a special indication to augment the pulmonary capacity. At the head of these diseases we must place pleurisy, or rather the sequelæ of pleurisy; pleuritic adhesions consecutive to effusions diminish the thorax of the affected side, and to such a degree that the patient generally bears for life the marks of the disease. By the practice of these respiratory gymnastics you will often succeed in causing this thoracic deformity to disappear.

Empyema has the same consequences, and here respiratory exercises will render you the same service; for my part I always have recourse to them. By these forced respirations and the chest-development which follows you will often break up pleuritic adhesions binding the lung to the vertebral column, and you will thus forward the coming together of the costal parietes and lungs, and the formation of those adhesions between the two surfaces which are so essential to the cure. In pulmonary emphysema, where, by reason of the damaged condition of the air-cells, the patient sees his pulmonary capacity diminishing from day to day, you can do much to obviate the inconveniences resulting therefrom by respiratory gymnastics.

As Basil Ferris has well shown, it is the expiratory act which is the most enfeebled in emphysema, and therefore he has proposed to make up for this deficiency by an elastic respirator, which I have described in my "New Medications" (Am. ed., p. 133).

Of late years all authorities who have written on gymnastics have insisted on the application of kinesitherapy to the prophylac-

tic treatment of pulmonary phthisis,—*i.e.*, before any morbid manifestation has appeared on the part of the lungs. To demonstrate the advantages of this kind of treatment, the following points have been emphasized:

First, our attention has been called to the narrowness of the chest in persons predisposed to tuberculosis. Fourmantin, in his treatise on the "Deformities of the Thorax," has shown that the thoracic index in tuberculous subjects is always very high, and varies between 133 and 152, while, on the other hand, in the normal state it ought always to be below 128; moreover, it is the rule, from a clinical point of view, to consider narrowness of the chest as favorable to the development of tuberculosis.

It has also been remarked that in tuberculous patients there is not only narrowness of the chest, but atrophy of the respiratory muscles. One of my most promising pupils, Dr. Stackler, has shown, in some researches made in my service, that contractility is always lessened in the pectoral muscles corresponding to the side of the chest the most affected.

It is easy to understand how gymnastic exercises may remedy this muscular atrophy and this narrowness of the chest by increasing the muscular force and respiratory capacity.

Burq has made plain by figures the favorable influence of these respiratory gymnastics on tuberculosis, by showing that persons who exercise their lungs are less likely to contract phthisis than other persons. Thus it is that, from statistics covering a period of twenty-six years, Burq has shown that the military musicians of Paris and of Versailles furnish three times as few phthisical patients as the other soldiers. Lastly (and here I continue citing only writings of recent date), Lagneau, in his successive communications on the measures of hygiene most suitable for lessening the frequency of phthisis, shows the influence of a sedentary life on the diminution of function of the respiratory organs, and, according to his researches, an inactive in-door life is one of the most favorable conditions for tuberculosis.

All these data, which were published before Koch's discovery, I believe to be still exact and reliable.

The question of a *suitable soil* remains always predominant, and if we are all continually exposed to the ravages of the bacilli and yet resist their incursions, it is because our organisms struggle to advantage against influences tending to destroy them. Gymnastic exercise is one of the most useful

agents for maintaining our forces in perfect equilibrium; hence, as viewed from this important side of the question, gymnastics must ever be called upon to render service in tuberculosis.

But this is not all; in these very data we find grounds on which to base our affirmation of the utility of these corporal exercises. You know that it is on these facts of bacteriology that we to-day base the generic union of scrofula with tuberculosis, and if clinical experience still finds clear-cut differences between them, pathological anatomy and bacteriology agree in confounding scrofula and tuberculosis in one and the same diathesis.

Now, in regard to scrofula, gymnastics constitute one of the most effectual curative means, by favoring the operations of hæmatisation, by augmenting the respiratory functions, by regulating the development of the body and improving nutrition.

If gymnastics may render us great service in the prophylactic treatment of tuberculosis, one should be very chary in their employ when the tuberculous lesions have attained a certain stage; you know well, in fact, that everything which congests the thoracic organs also augments the gravity of pulmonary accidents, and is especially likely to cause hæmoptysis.

Do not forget, also, that overwork and over-fatigue debilitate the organism, and thus make it a suitable culture soil for the microbes of tubercle. You should therefore enjoin on the tuberculously predisposed a certain moderation, variable according to the subjects, in the use of physical exercises.

The action of bodily exercises on the circulation gives scientific warrant for the application of these gymnastics, on the one hand to the treatment of diseases of the heart, on the other to the treatment of anæmia. If on the first point there is not unanimous agreement, this is not the case with respect to anæmia. Everybody, in fact, admits the happy influence of gymnastics in the therapy of anæmias, and in particular of chlorosis, and this, through the augmentation of the pulmonary capacity and the increased activity of the cardiac pulsations occasioned by these exercises.

You know that every respiratory act, by bringing a greater quantity of blood in contact with the oxygen of the air, promotes the gaseous exchanges and directly enhances the functions of the blood-globule. To this immediate action on the blood-globule are joined the direct effects on nutrition; the appetite is quickened, the muscular strength

augmented; and thus you understand the manifold benefits obtainable from gymnastics in the treatment of anæmia. In this category of exercises must be included walks in the open air, mountain excursions, swimming, horseback-riding, and all the feats of gymnastics which are not too severe and too exhausting.

It was in Germany that the idea originated of applying to the treatment of diseases of the heart, and in particular of fatty degenerations of this organ, corporal exercises and fatiguing tasks. Cœrtel, and his pupil Schweninger, have been the most earnest advocates of this method. They contend that by corporal exercises you excite the fibrillary contraction of the cardiac muscle, and thus augment the contractile power of the heart, which manifests itself by increase of the arterial tension. Moreover, the augmentation of the pulmonary capacity clears the lungs, combats cyanosis, and facilitates the contraction of the right ventricle.

Therefore these German authorities recommend two sorts of exercises,—walking on level ground, and, first and foremost, mountain-climbing. In subjecting himself to this latter exercise, the cardiac patient undergoes a real gymnastic training proportioned to his forces, a training which enables him every day to increase the distance to which he can climb. You see to-day this method applied in the Tyrol and in a great number of Alpine stations. Benches arranged at places here and there, and at variable heights, indicate the length of the ascent which the patient with heart-disease is expected to make every day.

Other medical authorities have gone even further, and if Schol, of Frankfort, limits the exercises imposed on cardiac patients to the practice of the Swedish method, Classen prescribes real gymnastic movements, and would have these patients engage in all the corporal exercises of the gymnasia. Sommerbrodt and Heilighenthal approve also the method of Cœrtel, and all these authorities are agreed in pushing the exercise, whether it be walking, climbing, gymnastics, till the cardiac patient experiences some degree of breathlessness and dyspnœa.

What is the therapeutic value of these procedures? To decide this question, we must review the physiological action of corporal exercises on the muscular structure of the heart.

You remember that in the last lecture I had something to say about over-fatigue of the heart, and the theories which have been

broached to explain the state of the heart after too exhausting labors. Whether you adopt the hypothesis of primary hypertrophy, or that of myocarditis, or even that of the toxic effect of leucomaines, the result is always the same,—that is, these fatigues lead to the arrhythmia of dilatation of the heart, and finally to asystolia. All writers who have studied overstrain of the heart are unanimous in this regard, and you will find in the descriptions of Peacock and Albutt in England, of Seitz, Frantzel, Otto, Hahn, Curshmann, and Leyden in Germany, and of Daga and Coustan in France, an almost absolute clinical identity as regards the symptoms of overstrain of the heart.

Having settled these facts, let us see what takes place when we attempt to apply corporal exercises to diseases of the heart. Whatever may be the cardiac affection which you are endeavoring to combat, whether it be alteration of the orifices or of the myocardium, the heart, in endeavoring to overcome its obstacles, tends always to undergo hypertrophy and degeneration. For if the heart, by the histological constitution of its muscular fibres, is a muscle similar to the muscles of animal life, it differs from these by the dominant fact that it is never at rest, and that you can never assign inaction as a cause of atrophy of this muscle, as you can of other muscles.

What, then, do corporal exercises effect? They increase the contractions of the heart, and favor its hypertrophy and degeneration. This result may be favorable in the period of compensation, but it is unfavorable in that of degeneration; and, as the one fatally entails the other, our conclusion is this, that extreme caution and prudence should be used in the employment of these hygienic means, and that if it is a good thing to exercise the heart within reasonable limits, there is always danger of exhausting that organ.

Hence all the tact and judgment of the experienced physician are brought into practice when it is a question of prescribing corporal exercises to patients affected with heart-disease, and such patients should be counselled to begin moderately, and increase little by little every day the amount of exercise which they can well bear. The Swedish gymnastics, graduated walks, ascents made in a methodical and progressive manner, may render you some service, but you should always watch your patient, and examine the results of these exercises on the heart and general circulation.

I have little to say respecting the applica-

tion of gymnastics to the troubles of digestion. I ought to recall to your minds, however, that these exercises augment the digestive functions. Kinesitherapy is applicable to the treatment of anorexia and dyspepsia, and one has only to test in order to verify the saying of Chomel, "A man digests with his legs as well as with his stomach."

But there is another point which I desire to emphasize, viz., the treatment of constipation by gymnastics, and, in particular, by abdominal gymnastics. In fact, just as we have seen described certain kinds of respiratory gymnastics, so also there is an aggregate of movements and of exercises to which has been given the name of abdominal gymnastics.

It is for the most part the Swedish physicians who have interested themselves in these abdominal gymnastics, and Nycander, of Stockholm, has given us a complete description of these exercises, which really appertain much more to massage than to gymnastics. These consist in passes, pressures, tappings, and shocks of the abdomen, of which I shall say more in the next lecture, when I come to speak of massage.

There are, however, other exercises of a purely gymnastic nature which very happily combat constipation, and augment in notable proportions the tonicity of the abdominal muscles. These exercises are of two orders. One kind consists in flexions of the trunk, the subject being either standing or sitting, the other in movements of elevation of the arms. In directing flexions of the body, you may to advantage prescribe the opposition gymnastics above described. The patient sits on a chair with his feet braced against a stool, then grasps with his hands the padded handles; then, with arms extended, executes a series of tractions and relaxations, which compress the abdomen.

To impart increased tonicity to the abdominal muscles, and especially to the rectus, whose relaxation is one of the causes of that obesity which Brillat-Savarin has characterized by the word *gastrophorous* (big-bellied), where you have a plump abdomen and relatively slender limbs, you can make use of Dally's *wall exercise*, which consists in standing a patient against a wall, making him bring his arms up stiffly above his head, then swing them back and forth describing a half-circle.

I come now to the application of gymnastics to muscular disorders. I have told you that gymnastics augment the volume of the muscles and regulate their contractions, hence

these exercises have been found of utility in three kinds of muscular affections,—atrophies, contractures, and chorea.

There is no better treatment of muscular atrophy, from whatever cause originating, than gymnastics, and here we witness the triumph of the Swedish Movement Cure, which enables us to limit the exercise to a given muscular group. You readily understand the service which this species of gymnastics may render in such cases. These muscular atrophies produce also those bony or articular deformities of the skeleton, the treatment of which occupies an important department of infantile surgery,—orthopedics. In these deformities nothing more conduces towards a cure than the practice of gymnastics. To accomplish this result numerous means have been proposed. Some have advised the use of mechanical appliances, more or less complex, for the correction of these deformities, and all sorts of methods have had their day, from Andry's Orthopedic Cure to that of Scarpa. At a later period we have seen the prevalence of Jules Guérin's method of tenotomy, which was long so popular among surgeons. Lastly, we come down to the modern period, when, under the influence of Bouvier, Bouland, of Dally, and of Pravaz, surgeons have studied with greater care the causes of these deformities, and have endeavored to indicate the treatment for each.

I need not recall to your minds the meaning of the words *kyphosis*, *lordosis*, and *scoliosis*.

You know that the first of these deformities is characterized by curvature of the vertebral column, with convexity posterior, while in *lordosis* the convexity is anterior, and in *scoliosis* the curvature is lateral.

In all these malformations gymnastics render an important service, but they should be directed by the best medical judgment. Care should be taken that the compensatory curvatures shall not augment the deformity already existing. It is, then, always under the eye of a skilful and experienced physician that such exercises should be undertaken.

Bear in mind that in the case of *kyphosis*, as well as of *lordosis*, the efficient cause, in the majority of cases, is tuberculous softening of the vertebræ, in consequence of which the vertebral column presents so feeble a resistance as to give way under strains and lead to grave consequences.

You should, then, wait before attempting gymnastic movements in such cases, and before neglecting the use of such fixation apparatuses as Bonnet's troughs, or the plaster

of Paris bandage, till cicatrization and the new ossification of the vertebral column shall allow you to interfere without danger. But there are deformities like *scoliosis*, and the spinal distortions so well described by Dally, which are quite amenable to gymnastic treatment.

Among the exercises which you can prescribe to your patients in order to promote straightening of the head and trunk, there is one mentioned by Tissot which deserves to find a place here on account of its simplicity. Tissot mentions the fact of a boarding-school mistress who, in order to compel her pupil boarders to walk erect, made them carry on their heads a light object of rather unstable equilibrium (such as a brick or piece of wood), and obliged them to walk and to run without letting this object fall.

This is, I think, a practice which might often be employed to advantage, for you must often, like myself, have noticed that in countries where women have the habit of carrying milk-pails and other burdens on their heads, they are distinguished for their portly, supple, and erect forms.

Swedish gymnastics and opposition gymnastics have considerable utility in the treatment of these deformities. To the muscular inequalities, which are the efficient cause of these deformities of the skeleton, must be opposed an inequality of efforts, so as to exercise the atrophied muscles, and immobilize the muscular group which, by its preponderance of action, has entailed the deformity of the skeleton. This result is attained by the resistance movements. For further particulars as to the orthopedic treatment of these deformities I must refer you to the works which have been published on this subject, and which are now quite numerous, such as, especially, those of Bouvier, of Malgaigne, of Dally, of Saint-Germain, of Leblond, etc.

Gymnastic exercise is quite as efficacious in the treatment of certain convulsive affections, and, in particular, of chorea. Since the introduction of gymnastic exercise into the hospitals, we have seen it applied to the treatment of chorea, and with striking success. Blache has given us the most complete particulars in this regard, showing us, in 1854, that out of one hundred and fifty-eight cases of chorea, one hundred and two recovered in thirty-nine days, and six in one hundred and twenty days under gymnastics associated with sulphurbaths. All previous and subsequent observers are unanimous in recognizing the good effects of gymnastics in this disease, and authorities

such as Germain Sée, Becquerel, Parrot, and Jules Simon are earnest advocates of the movement cure of chorea. What kind of bodily movements are likely to be of most benefit in this disease? Laisné, who has carried out this treatment under the direction of Blache, has furnished us the most precise indications in this regard, and his studies in this department have since been completed by Pichery, Leblond, Heiser, and others. These gymnastic applications vary according to the period of the disease and its intensity.

In the grave choreas, especially in those of paralytic form, only massage is practised; then, at a less intense period, the child is made to execute passive movements, affecting principally the parts where the choreic movements are most pronounced. These passive movements consist in delicately seizing the choreic member, and making it execute rhythmical movements, at the same time compelling the little patient to count in a loud tone of voice in concert with the preceptor. In exercises of this kind there is demanded on the part of the preceptor a great deal of patience and no little skill to keep from struggling with the little patient and yielding to his convulsive movements. When these movements are still less intense, you can make the child perform some exercises on the "orthopedic ladder." Lastly, when the incoordination becomes still less, you may have the child execute movements of a decidedly rhythmical character, and here chanting, by giving a cadence to these movements, has a real utility.

To sum up. Extreme skill and prudence are required in the employment of gymnastics in the treatment of chorea, and an experienced physician or a master of gymnastics ought always to direct them.

The application of gymnastics to chorea leads me to speak of the gymnastic treatment of affections of the nervous system in general.

I have told you that without adopting the exclusive opinion of DuBois-Reymond, who sees in gymnastics only an exercise of the cerebro-spinal system, I am inclined to regard gymnastics as promotive of equilibrium between the functions of the brain and spinal cord. Therefore to all nervous, ataxic, neurasthenic persons, a class of patients so numerous in our large cities, to all those who are broken down by severe mental work, to all who by reason of being entirely devoted to sedentary official duties give little or no time

to the exercises of the body, gymnastics are not only useful but a necessity.

It is not enough to know that in such cases gymnastics may give marvellous results, you must also be able to apply them, and here you will meet with difficulties. If your patient is a man, the thing is easy enough; and if some of our patients object to going to the gymnasium, almost all are willing to try boxing and fencing. But where the question presents greater difficulty is in the case of female patients. All naturally object to gymnastics properly so called, and you hardly like to propose, or they to accept, fencing as an exercise. As for horseback riding, this kind of exercise is quite popular among our neighbors across the Channel, but it is repugnant to our French ladies. Horseback-riding, from a gymnastic point of view, is an exercise which develops unequally the muscles of the organism, but which, at the same time, presents the great advantage of requiring early rising on the part of the patient and rides in the open air. Unfortunately, this is an exercise which only those in somewhat affluent circumstances can afford. As for the middle and poorer classes, you will have to be content to order long walks, especially in the open country, mountain excursions, and sports, such as lawn-tennis and croquet. All your knowledge and judgment will be demanded in ordering exercises appropriate to the position in life and the situation of the patient who consults you.

We now pass on to the application of gymnastics to the treatment of hysteria.

Are gymnastics capable of curing hysteria?

I cannot say yes to this question. I believe there are even cases of hysteria where gymnastics are more detrimental than useful. At the same time there are other cases where this multiform neurosis may be usefully modified by kinesitherapy, especially if you combine hydrotherapy with it. Muscular fatigue, in fact, often enables these patients (if I may use the expression) to *discharge* their nervous systems,—to work off their surplus of force, and under these two hygienic means, physical exercise and hydrotherapy, we see sleep supervene and the nervous phenomena calmed. I have had a little experience in this kind of treatment, having been enabled for more than a year, owing to the kindness of Pichery, to try his opposition gymnastics on a great many female patients in my wards.

You must, like myself, have been often impressed by the fact that while all, or nearly all, our patients are men who have led active lives, demanding a considerable and often

excessive expenditure of muscular forces, our female patients, on the other hand, are persons who have pursued sedentary occupations, which, whether carried on sitting or standing, do not demand much labor on the part of the muscles. Hence we see a series of morbid phenomena resulting from these habits of inactivity, phenomena which we may very happily combat by gymnastics. It is even to be desired that these gymnastic exercises should be more generally adopted in our hospitals, and that we may be enabled to give our poor patients the benefit of this salutary association of hydrotherapy and corporal exercises.

If the multiple nervous states connected with hysteria are tributary to treatment by gymnastics, there is another neurosis quite as grave, or even more so, namely, epilepsy, in which great moderation is requisite in the use of gymnastics. To the epileptic, horseback-riding and swimming are absolutely interdicted; a fit during these exercises might result in death. It is the same with all the exercises of the gymnasium performed with apparatus. You can, however, make free use of those kinds of gymnastics which give suppleness, and which I have called "*gymnastique d'assouplissement*." At the Salpêtrière, all the young epileptics are made to perform these exercises of suppleness, and very good results are obtained therefrom, both from the point of view of physical development and the prolongation of the interval between the fits. Do not forget that walking, as well as gardening and farm-work, have a favorable influence in the treatment of this disease.

In idiocy, which is sometimes found associated with epilepsy, gymnastics have a favorable influence. In the case of these forlorn, pitiable beings, who have an instinctive prompting to locomotion, which they manifest by disordered and aimless movements, gymnastics regulate these movements, habituate the child to obedience, lessen the tendencies to masturbation, and tend in a certain measure to develop intelligence. Hence all authorities who have had to do with the education of idiots—Esquirol, Belhomme, Delasiauve, Voisin, Bourneville—have remarked the beneficial effects of gymnastics in the training of these unfortunates, and you can see at Bicêtre, in the idiot department, the brilliant results obtained by Pichery from gymnastics. Here it is movements of an exact, rhythmical character—movements in concert, accompanied by singing—which seem to give the best results.

But I have told you that it is chiefly by their

general action on nutrition that gymnastics take a preponderant place in the treatment of diseases. In exciting the organic combustions by the increase of the respiratory capacity, in energizing the muscular and inter-molecular oxidations, in favoring the vitality of the cell, gymnastic exercise is perhaps the most powerful modifier of nutrition. Hence in all diseases where nutrition is compromised you will find that kinesitherapy operates favorably.

There are three diseases where nutrition is especially at fault: obesity, the uric diathesis and gout, and diabetes. In the treatment of these three diseases exercise plays a preponderant part. As for obesity, I have already in former lectures shown you what sort of hygienic rules the corpulent should follow, and in this hygiene I have given a place to exercises and massage. To this point, then, I need not return. Here it is especially to training practices that you must resort, and a rigorous system of training is more beneficial than any other kind of treatment. I must also remind you of the utility of abdominal gymnastics, and of such movements above described as "wall exercises," in the case of individuals who, without being absolutely polysarcic, have the abdomen a little too prominent (the big-bellied men of Brillat-Savarin). This condition results from a flabby, toneless state of the abdominal muscles, which you may often signally remedy by the exercises which I have just pointed out.

In the uric diathesis and in gout exercise is indispensable, and this is a fact known from all antiquity. Under exercise the waste matters of the organic combustions are better got rid of, and uric acid tends to disappear.

I cannot go back to this question of urea and uric acid, which we treated quite fully last year while on the subject of diet in gout. It is enough for me to remind you that the production of uric acid, whatever view we may take of its origin, is in direct relation with a slowing of nutrition in general, and this is combated by exercise, which has an opposite effect. Interrogate most of your gouty patients and you will find that the larger part of them err by want of exercise.

Besides the phenomena of combustion, corporal exercises promote perspiration in gouty patients, and this is salutary because, the cutaneous surface being vicarious with the kidneys, urea and uric acid are eliminated by this excretory channel; but these exercises must not be carried too far. Scudamore long since showed us that often attacks of ne-

phritic colic or of gout supervene in gouty subjects after fatiguing tasks, such, for instance, as too prolonged devotion to the pleasures of the chase, and Lécorché has cited facts of this kind. You must, then, insist on daily exercise in moderate amount, and in proportion to the state of your patient's forces.

Salmouth has even claimed that by forced marches one may arrest an attack of gout in its incipency. Unfortunately, this is not so, and when once an attack is begun, even passive exercises must be forbidden. When deformity of the limbs or muscular atrophy has rendered walking impossible, it is not even then necessary to abandon exercise, and you will see in the next lecture that massage will render you excellent service; you can also at this period recommend horseback- or carriage-riding.

Besides nephritic colic, the gouty subject is liable to biliary colic. In biliary lithiasis gymnastics are useful; they favor the combustion of cholesterine, the basis of calculi, by the activity which they give to the organic exchanges. At other times when limited to abdominal gymnastics, such exercise facilitates the flow of bile and prevents its stagnation, and this of itself is a matter of no small moment.

Lastly, in diabetes the action of gymnastics, as Bouchardat has shown, is of the first importance, and constitutes, with dieting, the basis of the hygienic regimen of this disease. Corporal exercises augment the combustions without increasing the proportion of urea, diminish the quantity of sugar, and favor the functions of the skin. Here, as in polysarcoma, the general rules of training must be followed, caution being taken not unduly to fatigue the patient.

Recall to mind that spirited and charming volume of Cyr, entitled "The Impressions and Adventures of a Diabetic" (Paris, 1881). Cyr's diabetic patient travels over the different countries of Europe, and in each metropolis where he stops he consults some physician eminent in the treatment of diabetes. In Paris he applies to a certain Prof. P. (he should have said Prof. B., for he has given an exact picture of my venerated master Bouchardat), and under the title of an "original consultation" Cyr gives the routine of daily exercises and the bill of fare prescribed for his patient for one week. The exercises were to consist in digging the earth and removing the soil with a wheelbarrow, in marching with a company of infantry, in several times making the ascent of the towers of Notre Dame, and in

walking around Paris by the boulevards in the suburbs, etc. While making due allowance for the imagination of the romancer, it must be admitted that there is a good deal of common sense in the hygienic prescriptions there laid down, and that it is a good thing to order exercise under all its forms to the diabetic.

Only you must bear in mind that diabetics are generally aged persons, and they have neither the courage nor the energy of one of our recent chemists, whose death France deplores, and who, when attacked with diabetes, became one of the noted gymnasts of the day. The greater part of these patients refuse to go to the gymnasium. In such cases, besides fencing, which is sometimes acceptable, and long walks, I cannot too much recommend gardening and joinery. Nothing, in fact, can be better than garden-work; besides labor in the open air, the patient in digging, weeding, raking his garden, executes numerous muscular movements which cause fatigue and sweating; but all diabetics, unfortunately, do not possess gardens. To such persons I can earnestly recommend the use of tools and joiner-work; the patient may, at a little expense, provide himself with a little workshop and a set of tools, and he will be likely to take a lively interest in the fabrication of objects which with a little practice he can learn to make, and he will find his muscular forces greatly increased thereby; therefore I would say to diabetic patients, if you have any natural mechanical ingenuity, apply yourselves to these healthful tasks.

Such are the principal applications of gymnastics to the treatment of diseases. In the next lecture I shall take up a subject which has many points in common with gymnastics, namely, massage.

*THE INFLUENCE OF ANTIFEBRIN, SALICYLIC ACID, AND CARBOLIC ACID
ON NORMAL AND ABNORMAL
BODILY TEMPERATURE.*

BY H. A. HARE, M.D. (UNIV. OF PA.).*

(Continued from page 389.)

II. SALICYLIC ACID.

IN ten experiments as to the influence of salicylic acid on the normal rectal temperature of the rabbit, the following results were

* Demonstrator of Experimental Therapeutics and Instructor in Physical Diagnosis in the University of Pennsylvania.

obtained: In six experiments there was quite a marked fall of bodily temperature. In two others it rose slightly, while in the remaining two there was no change of any moment whatsoever. The writer is unable to give any explanation of these somewhat varying results, although one of them may be possibly explained by the struggling which took place when the animal was picked up. It may be, too, that in the remaining experiments the drug failed to reach the general system owing to delayed absorption, since, although an endeavor was made to place the hypodermic needle in the same region in each animal, it is perfectly possible that in one or two instances the drug may have entered in a spot where absorption went on slowly. That the drug does reduce normal bodily temperature seems proven not only by the majority of these experiments, but also by the results which were obtained in the experiments on the circulation and temperature in the dog. Thus we find on looking at the charts that in all five experiments on the normal animal when attached to the manometer there was a very marked fall in the temperature of the body.

These results are directly opposed to those obtained by Prof. Sée* and Fürbringer,† the first of whom used enormous doses, as much as 150 grains for a man, without finding any change in his temperature.

Prof. Sée gave the drug by the stomach, and, as Kohler has proved that the same investigator's experiments on the action of this drug on the circulation were made before the drug was absorbed, the same fallacy may exist here.

Gedl,‡ who gave man doses varying from 46 to 78 grains, found that in two cases there was no result, in three a lessening in the daily alterations in temperature, in three a slight fall of temperature, and in one a decided fall of 0.8° C.

Danilewsky states that the effects of the drug are slight and inconstant, while Mr. North§ found that the acid prevented very powerfully the rise of temperature following severe exercise.

Notwithstanding the somewhat contradictory results obtained by these experiments, I think the bulk of evidence points to a reduction of normal temperature under the influence of this drug, and that there is no doubt but that salicylic acid in very large doses decreases temperature very greatly.

I report the following experiments in detail:

Experiment 1.—Rabbit; weight, 2 pounds. Black doe.

Time. P.M.	Drug.	Rec. temp.	Remarks.
12.25	102½°	
12.30	1 gr.	
12.55	102°	
1.15	101½°	Animal huddles closely to the other, and apparently feels cold.
1.35	102°	
1.55	101½°	
2.15	102°	
2.35	102½°	
3.35	102½°	Fall of temperature = 1½° F.

Experiment 2.—Rabbit; weight, 2 pounds. White doe.

Time. P.M.	Drug.	Rec. temp.	Remarks.
3.40	103½°	
3.45	1 gr.	Quiet.
4.05	103°	
4.25	102°	
5.25	101½°	
5.45	102½°	
6.05	103½°	
6.25	103½°	
6.45	103½°	Fall of temperature 2½° F.

Passing on to a consideration of the action of this acid on the circulation under normal conditions and in fever (ten experiments), we find that there seems to exist no relationship between arterial pressure and the temperature, and that under both conditions the drug causes a rise rather than a fall of pressure. On the abnormal or pyretic temperature salicylic acid in moderate or small doses seems to possess but little influence. Other observers, whose observations have been chiefly confined to the bedside, report that the drug has antipyretic powers, although even its most vehement supporters do not claim that it is very reliable as an antipyretic.

*Charts showing Arterial Pressure and its Relationship to Temperature, also showing Fall of Temperature produced by Salicylic Acid.**

Experiment 3.—Rabbit ; weight, 3 pounds.

Experiment 4.—Dog ; weight, 12½ pounds.

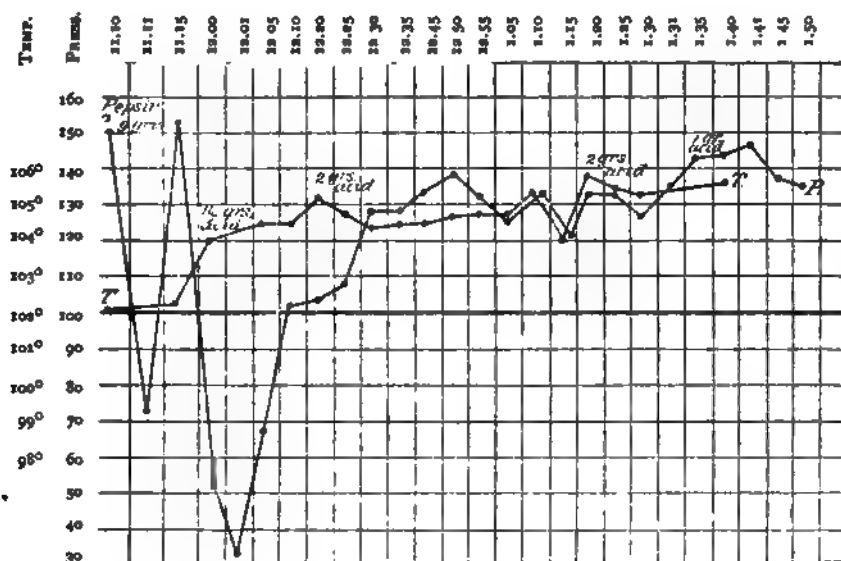

With Fever.

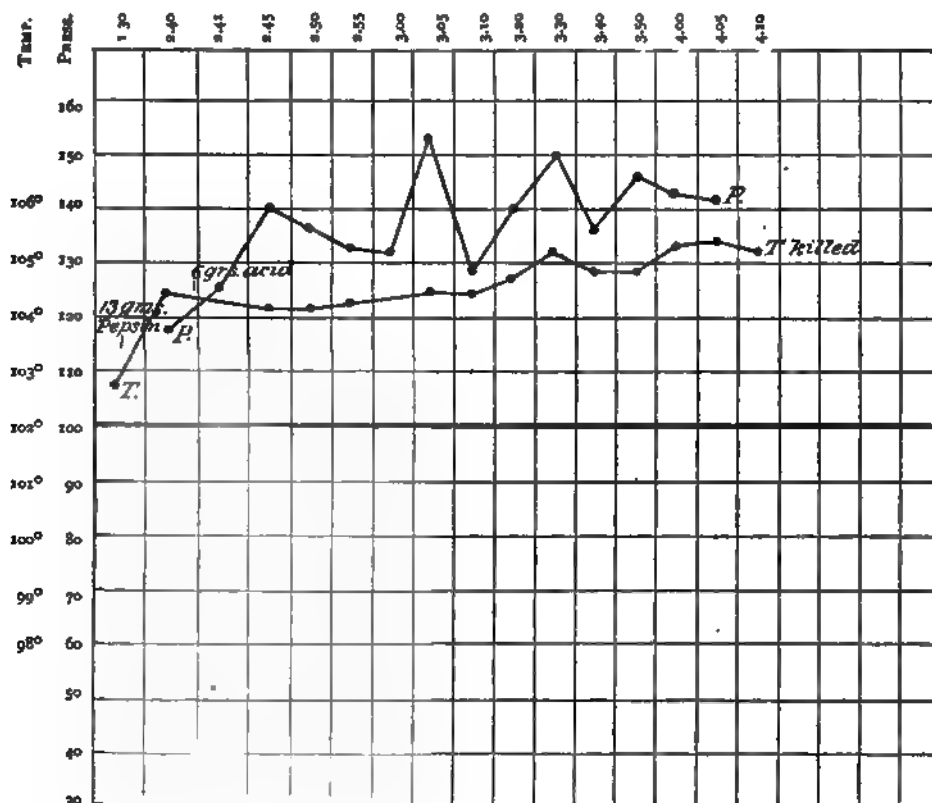

* It is proper to state that the details of many of the experiments have been left out owing to lack of space, not only in this portion of the paper but in the other portions also. In all, ninety experiments were performed, thirty on each drug.

Charts showing Arterial Pressure and its Relationship to Temperature, also showing Fall of Temperature produced by Salicylic Acid (Continued).

Experiment 5.—Dog; weight, 15 pounds.

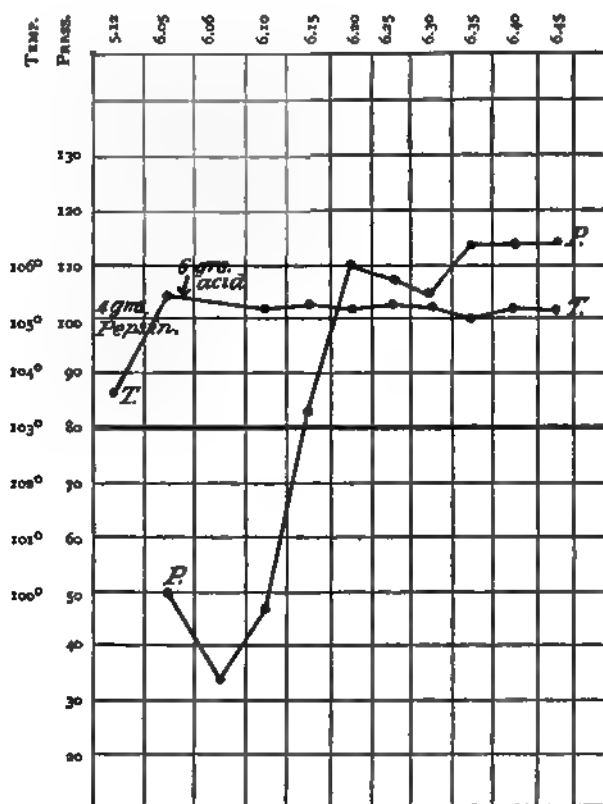

Experiment 6.—Dog; weight, 17 pounds.

Charts showing Arterial Pressure and its Relationship to Temperature, also showing Fall of Temperature produced by Salicylic Acid (Continued).

Experiment 7.—Dog; weight, 32 pounds.

The study of the action of this drug on the production and dissipation of heat is the most interesting portion of its investigation, and a somewhat minute analysis of the results is therefore not out of place.

We find that in two experiments there was a *gain* of both dissipation and production, and that in the first of these the two functions balanced each other, while the second (No. 9) dissipation was very markedly increased over production.

In two other experiments there was a loss or decrease of both functions (Nos. 10 and 11).

In No. 10 dissipation was decreased more than was production, while in No. 11 heat production was decreased more than dissipation.

In No. 12 there was loss of dissipation and gain of production.

It will be seen, therefore, that the results obtained as to the method by which normal

temperature is decreased are not concordant, but from the first four experiments it seems evident that the drug acts on both functions in reducing normal temperature.

Experiment 8.—Dog; weight, 20 pounds.

On analyzing the calorimetrical observations during fever we find that in one instance

† The word "loss" is used as synonymous with decrease.

(No. 13) we have a gain of both functions, but that dissipation being increased more than was production, temperature was decreased thereby. In No. 14 both functions were decreased, but that production was decreased far more than was dissipation, thereby permitting a fall of temperature.

Again, in No. 15 dissipation was not influenced, while production was decreased.

In No. 16 there was loss of both functions, dissipation being more decreased than production.

In No. 17 the same condition of affairs also held.

These results are much more discordant than those obtained on normal temperature, and agree with the experiments already given, showing that the drug does not have any positive power over fever.

Thus, in one instance, the fall of temperature depended on increased dissipation, and in two others on decreased production, while in the remaining experiments there was a rise in temperature due to a greater failure of dissipation than production.

Experiment 13.—Dog; weight, 12 pounds.

Hourly loss of production after drug 8.313

Result.—Loss of dissipation and production, the loss of dissipation being the greater.

A SUMMARY OF THE ACTION OF SALICYLIC ACID ON BODILY TEMPERATURE.

1. *Salicylic acid* has the power to reduce slightly normal bodily heat.

2. *Salicylic acid*, according to the writer's experiments, has but little power over pyretic temperature.

3. *Salicylic acid*, when acting on either normal or abnormal temperature, does not seem to have much influence on the circulation either in regard to pulse-rate or arterial pressure. Any change, when it occurs, seems to be an increase of arterial pressure rather than a decrease, and this increase occurred more markedly in the normal than in the pyretic animal.

4. *Salicylic acid*, in reducing normal tem-

perature, probably acts on both functions, namely, production and dissipation, while it seems to act very uncertainly and irregularly when reducing high temperature, failing frequently, as before stated, to prevent an increase of bodily heat.

(To be continued.)

CROUPOUS PNEUMONIA OF THE APEX ATTENDED BY A UNIQUE SYMPTOM.

BY LOUIS STARR, M.D.*

THOUGH the histories of isolated cases are, as a rule, unread, and therefore useless, I cannot but believe that the following details of a case of apical pneumonia will be of interest to all students of pediatrics, as they present a symptom that has certainly never occurred before in my somewhat extended experience with this peculiar form of pneumonitis, and which, so far as I know, has never been recorded.

Percy P., a well-nourished English boy of 4 years, was admitted to my wards in the Children's Hospital on April 15, 1887. There was no history of tuberculosis, and, with the exception of an attack of scarlatina sixteen months before, the child had enjoyed perfect health. On the day before admission he was at school, though while there he was in a febrile state and drank freely of water, afterwards vomiting and complaining of pain in his head. That night he was restless and feverish, and had short and rapid breathing, the expiratory movement being attended by a grunt or complaint of pain.

When first seen the little patient's condition was as follows: face drowsy in expression, a slight herpetic eruption on lips, and a bright circumscribed flush on the right cheek; decubitus right lateral, with the head markedly retracted, the neck stiff, the spine arched forward, the arms pressed close to the sides and folded across the chest, the thighs drawn up towards the abdomen, the legs flexed on the thighs and the feet crossed,—a decided *en chien de fusil* position in fact; tongue heavily coated, breath offensive, no vomiting, bowels active, and abdomen rather distended; respiration 40 per minute, with active nostrils, grunting expiration, and frequent hacking cough; pulse 140, regular and quick; skin dry; axillary temperature 104° F.; no *tache cérébrale* nor hyperæsthesia; urine scanty and

* Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania.

heavy with lithates ; cerebral activity blunted, but patient readily roused ; well-marked physical signs of consolidation of the upper lobe of the right lung.

The subsequent course of the case can be seen at a glance from the subjoined table :

Day of disease.	Temperature.		Pulse.		Respiration.		Movements of bowels.
	M.	E.	M.	E.	M.	E.	
2	104 ⁰	104 ⁰	140	...	40

* Can only account for this fall by shock consequent upon the long journey to hospital.

† Convalescence thoroughly established.

The peculiar decubitus,—the special feature of the case,—together with the other general symptoms, continued unchanged in character throughout the illness, and the former did not diminish until the temperature began to fall on the ninth day, and did not disappear entirely until the temperature settled to the normal line on the fourteenth day.

The treatment consisted of a liquid diet,—milk and beef-tea in small quantities at short intervals,—quinine (by suppository) and whiskey to maintain the general vigor, digitalis to slow and strengthen the action of the heart, counter-irritation, and a cotton jacket over the right lung. Bromide of potassium was administered in small but repeated doses for several days during the height of the attack, on account of the marked cervico-spinal rigidity, and carbonate of ammonium at the end to aid in stimulating the heart.

In ordinary cases of cerebral pneumonia there is little to draw attention to the lungs. In place of flushed cheeks, active nostrils, rapid breathing, frequent hacking cough, and high fever, the face is pale, the nares passive, the cough slight or absent, the breathing quiet, and the fever moderate in degree. On the other hand there are vertigo, muscular twitchings, and marked and persisting drowsiness sometimes approaching stupor ; all pointing to cerebral disease. Without care a mistake is easy. Suspicion is first excited by noting the absence of certain prominent features of tubercular meningitis. Thus there is no history of an insidious and protracted

prodromal period, no obstinate vomiting nor constipation, no retraction of the abdomen, no slowing of the pulse, no irregular, sighing respiration, no *tache cérébrale*, no squinting or irregularity of the pupils, and no absolute unconsciousness. Should these points strike the observer, and he remember that there is such a disease as cerebral pneumonia, an examination of the chest will follow and the key to a diagnosis be found.

In the case I have reported there were quite enough symptoms to at once direct examination to the lungs, at the same time the drowsiness of cerebral pneumonia and the peculiar decubitus of tubercular meningitis were prominent. Having examined the lungs little difficulty was experienced in reaching a conclusion, proved to be correct by the subsequent course of the disease. This, then, was an easy case, but it is none the less instructive. It carries a warning that may save future anxiety and delay, and prevent the embarrassment of a mistake.

ACUTE CEREBRO-SPINAL MENINGITIS.

By JOSEPH X. ZITKE, M.D., BATESVILLE, IND.

IT is a fact well known to the general profession that in the course of years—sometimes after a lapse of half a century—there are seasons in which cerebro-spinal meningitis appears suddenly and unexpectedly even in the farthest districts from large cities in an epidemic form, spreading rapidly over a certain district of the territory, and after a stay of some weeks or months disappears again as suddenly as it had come in.

During the last twelve years of my practice I had occasion to observe three such epidemics of this dreadful disease, and I must confess that the mortality of two of them was rather more than distressing to me to contemplate. The last one was, perhaps, not of the most virulent type, hence, perhaps, the more satisfactory results observed and obtained.

Besides this form of cerebro-spinal meningitis, there appears, also, another one (a less independent form), complicating other diseases, and thus lessening the at best dubious chances of recovery. It is this latter form of the disease that seems to me to have caused a considerable confusion in the pathology of the disease, for many of the best authors seem to consider meningitis as the

primary, and the accompanying disease as the secondary, pathological state of the body, whilst other writers, and perhaps the more profound thinkers of the profession, consider meningitis as a secondary pathological process following in the wake of another one,—the primary.

This question, however unimportant it may seem, has nevertheless a great significance and importance in general practice, to which I shall return again when considering the etiology and nature of cerebro-spinal meningitis.

That cerebro-spinal meningitis is by no means one of the new diseases of the nineteenth century, as some of our medical authorities would try to convince us, can be easily proven by the study of ancient medical records, and by the symptomatological history of the many epidemics which devastated Europe during the latter period of the middle ages and during the first centuries of the new era. Thus, if we consider the most important symptoms of the historically recorded plagues of the past centuries, we shall find it specially mentioned by Simon de Lovicka, "De preservatione a pestilentia," vol. i. pars i., folio edition. Pragensis, 1537.

Other authors of those years give the same symptoms of the fatal plague which scourged Europe so dreadfully in those times. Another but very little differing account can be found in the work of the same author, entitled "Enchiridion Medicinæ," Krakau edition, 1537.

Johanes Agricola gives the history of the pest in a work entitled "Historia Pestis Nigræ," which was published in Prague in 1535, at which time the university had the greatest reputation as to medical studies. Soon after the work of Master Agricola, another professor of the same university published a book on the same subject. It was Magister Udalricus Leonorus a Cauba (1535), a graduate of Padua, who opposed quite earnestly all *blood-letting and violent administration of salts* in the disease, and advised chiefly rest and "regimen corroborans naturam debilitatam." He also compounded a bolus, which he called "bolus pestilentiae," and which he prescribed to some noble lord, and vouched for its action as "qui operat sedative, dolorem mitigat, somnum excitat, et sic per quietem cerebri totum corpus sanatur." (How is that for 1535?) He seems to have been a rather stout man of considerable adipose tissue, and both his success in treating the plague and his colossal, fat figure gave origin to the following couplet:

"Tam desperanti devit hanc*—Leonorus nicrete
Excellens medica—corpore crassus homo."

From which it is evident that even in the sixteenth century professional reputation was considerably united with the exterior of the doctor.

Another writer on the same subject is Petrus Andreas Mathioli (1552), an Italian, a graduate of Padua, Paris, and Prague, who wrote the celebrated work "Epistolarum Medicinalium libri quinque" (Pragæ, 1561), which work was later translated both into German and Bohemian, though it met with a great opposition at first from the medical faculty of the university, chiefly on account of the author's opposition to blood-letting and salts in the plague, which latter disease he calls "morbus maculatus," or for the first time, "pestilentia cerebri maculata nigra."

It would be too long and too tedious if I should try to introduce here even the names of all the authors of the middle ages who wrote about the celebrated plagues of Germany, Italy, and England, however barren English literature may be on that subject. From their writings, however, and from the symptoms enumerated and so clearly stated, we can hardly doubt that the celebrated plagues of the middle ages and the pestilent, acute, and malignant form of cerebro-spinal meningitis, if not the same disease, were surely very consanguineous, and of a very near and true relationship.

Thus the well-known pestilence which followed the bloody, ambitious war of Charles V., of Germany, and Francis I., of France, had so many characteristic symptoms of our cerebro-spinal meningitis, that it is very hard to doubt their identity of nature. Though very little is said about this renowned plague in the works of Master Ambrosius Parré, or in those of Magister Amboise, yet an old volume which for many years was preserved in the monastic libraries of Ossegg, and which was attributed to the celebrated perfumer, astrologer, and poisoner of Queen Catharine de Medici, Renée, the Florentine, gave such accurate descriptions of the symptoms of the pestilence that they hardly differ from those given by other writers of more professional character and respectability, and thus indirectly confirm, which directly to do they should perhaps never be called on.

The further progress of the cerebro-spinal meningitis during the last two centuries all over the world is ably traced in Pepper's

* Sanitatem.

"System of Medicine," under the head of "Cerebro-Spinal Meningitis" (vol. i.). The name by which this special disease was designated was widely differing in the various countries.

Thus we find it called "pestis," "pestis nigra," "febris maculata," "pestis maculata cerebri celer," "febris maculata nigra," "la febre convulsiva," "febbre soporosa," "fièvre satanique," "fièvre maculée." The popular name in England and United States was the "spotted fever," which name is even now used by the people, though every educated physician should avoid it, because it expresses by no means the meaning of "cerebro-spinal meningitis." For, if we consider the multitude of diseases which terminate with a cutaneous purpuric and hemorrhagic eruption of the skin, it would be very difficult for us to form a definite idea from such an indefinite and general nomenclature of a pathological state as is expressed by the words "spotted fever." The German and Slavonic popular term—das "steifneckfieber"—is far more better chosen, and gives a more clear idea of "cerebro-spinal meningitis," because it recalls at once to the mind the most characteristic symptom of the disease, and that of such an importance to the physician that in many cases of doubtful nature where no positive diagnosis has been or could be made, this essential symptom settled the diagnosis of cerebro-spinal meningitis.

As to the etiology of cerebro-spinal meningitis but little can be said. It appears that in all countries can be found its field of "deadly action;" that it can be traced far in the north and deep to the south. However, it is mostly at home in a warm climate. That it is not caused by uncleanness is proved by its appearance in the houses of the rich as well as of the poor, and perhaps more among the better class of mankind. Another characteristic proof seems to be in the fact that cerebro-spinal meningitis has not yet visited Russia and Poland. Whether a micrococcus or bacillus, introduced in some way into the animal economy, is its cause is till now not determined. But, if we consider the fact that so many diseases are now charged to the general bill of these microscopic organisms, we can hardly deny the general possibility.

The persons mostly affected by the disease are young children, and persons from thirty to thirty-five years of age. Males seem to have more affinity for the disease. This latter fact was so well known to the medical men of the middle ages that Archbishop Albicus, for-

merly the dean of the medical faculty of Prague and the body physician of the Emperor Charles IV., says, in his work "De Pesti Maculata Nigra," "Mares ab ipsa afficiuntur plus quam feminae, et mortalitas major est in genere masculino, quam in feminino."

Some of our later observers, chiefly of French origin, try to establish among the causes of the disease homesickness, excesses in Baccho et Venere, sudden changes of temperature, dry and wet seasons following in quick succession, sudden mental shock, and finally violent mental emotion.

It is hard to form a definite opinion where so many various states contend with each other for acceptance, but if we consider the fact that the greater number of victims of cerebro-spinal meningitis are young children, and boys and girls hardly yet arrived at the age of puberty, we can surely eliminate from the above-named list the excesses in Baccho et Venere, as well as the sudden mental shocks and mental emotions.

As to the disease itself, after years of study, it is finally determined that it is *not contagious*. The forms of cerebro-spinal meningitis, as observed on the sick-bed, are various, hence many medical writers made so many distinctions and contra-distinctions among the different types of the disease that they are very apt more to confuse the student than to instruct him. The whole divisions and classification of the various types of cerebro-spinal meningitis may be found in Pepper's "System of Medicine" in all its fulness, and may be very interesting reading for the experienced physician, but by no means the proper food for the mind of the young student or physician, whose mind has not yet in its possession a clear and firm picture of the general character of cerebro-spinal meningitis.

For this reason I prefer the simple division of Niemeyer, who recognizes but *one form* of acute cerebro-spinal meningitis, subject, however, to changes and modifications of its symptoms according to the virulence and acuteness of the disease itself and the psychological and physiological qualities and status of the patient. Retaining thus these two chief points in view, and submitting to our consideration all the changes which an inflammatory, acute process does and must produce in various persons of various temperaments, ages, nutrition, and development; also considering now one, now another of the pathologically important and characteristic symptoms which may become prominent, we shall easily form for ourselves all the various types

of cerebro-spinal meningitis that fill our text-books and mislead the beginner, and see them for ourselves without any didactic teaching, and without any following confusion and the consequent uncertainty and doubt.

Some other existing forms of cerebro-spinal meningitis are mostly not of primary origin, but of secondary nature. Such cases are usually observed as following in consequence of pneumonia or pleurisy, exanthematic fevers or other infectious diseases, the most important of which are Bright's disease and typhoid fever.

Another class of the same disease is also observed as produced mostly by physical forces, as blows on the head, falls from an elevation, etc. It seems also that exposure to the hot rays of the sun can produce cerebro-spinal meningitis.

Finally, the last class of this secondary origin is the cerebro-spinal meningitis called forth by syphilis, which is clearly described in Ziemssen's "Handbook."

The epidemic appearance of cerebro-spinal meningitis in large barracks and penitentiaries seems to be a kind of blood-poisoning, the specific nature of which is not yet well determined.

Symptoms, Prognosis, and Treatment.—Cerebro-spinal meningitis is one of those diseases that attack a human being often suddenly and without any *stadium prodromorum*. A child, a boy or girl, may appear quite healthy at supper-time, may not complain at all, or its appetite may be not quite to the normal, when suddenly near or after midnight the whole household is awakened from sleep by its complaints of a violent headache. The face is flushed, the eyes bright, the pupil dilated. The child moans continually, interrupting the moaning by violent screams, which are heard all over the house. These screams, which, at the beginning, may be heard but at long intervals, become more and more frequent, the patient becomes restless, throws his hands, his feet, his whole body all over the bed. All the body is in motion except the head, which usually is kept at rest. By and by convulsions set in, which terminate by a comatose condition, which is interrupted by low, meaningless, plaintive moaning, and which usually ends in death after a lapse of from forty-eight hours to five or six days. At the same time the stomach is usually deranged, frequent vomitings set in, which, by the violent strain and by the increased hyperæmia of the cerebral blood-vessels, still further augment the pain, and thereby make

the patient often appear as dead or nearly dying.

The bowels are usually constipated, but I have seen cases in which they have been very loose, and by this very symptom, and the tenderness in the abdominal region, and the great headache, might have led to a mistaken diagnosis if the thermometer had not shown us the right direction in which to travel in quest of the true one.

The temperature is usually in no proportion to the violence of the general symptoms, and seldom reaches 102°. The pulse is usually slow, and very seldom over 110 beats in a minute. The tongue is covered with a whitish or light yellow fur, while the lips bear evidence of the existence of a herpes labialis. In some cases a roseola eruption may be observed on the chest and abdomen. The thirst is usually great, yet, as soon as a drop of water has reached the stomach, the awful straining of vomitus sets in. Sometimes a slight strabismus may be observed in one or the other eye, sometimes in both. The same may be said of deafness, which occurs, in the majority of cases, at the same time as the strabismus has appeared. On the third, fourth, sometimes even not till the sixth day, the characteristic symptom of cerebro-spinal meningitis sets in,—i.e., the stiff neck, produced by the contraction of the long neck-muscles,—and thus removes all doubts, if any were existing, in respect to the correctness of the diagnosis.

The prognosis is always doubtful and serious, the termination usually fatal. Indeed, as long as the old treatment was strongly and unmercifully followed, with its bleeding, leeches, cantharides-plaster, etc., all used and applied as if man was made from a mass of immutable, never-changing, never-differing material, the general death-rate was appalling. Some twenty years ago, in an epidemic in Austria, of one hundred patients confined in the hospital for treatment, only three escaped with their lives. But in what a state! It had been, perhaps, better for them if they had followed the great caravan of their fellow-sufferers.

In fact, though science has furnished to our hands in these days better knowledge of the pathology of the disease and more suitable drugs for its resistance, it is yet true that the general mortality of cerebro-spinal meningitis is very great, and that the general state of health of the convalescent is far from being envied. Indeed, experience teaches that many of those convalescents remain afflicted for a

long time, if not for the whole term of their natural life, with one or another of the many diseases which have taken their origin from the destructive process of the inflammation of the meninges and consequent effusion into the arachnoid cavities. Thus, we find some suffering from a life-long photophobia, others from strabismus, from deafness, blindness, or from general or partial paralysis of some part. And, again, others, though the animal functions of their organisms seem not to have been deranged at all, lose all their mental abilities and capacities, become idiotic, demented, and even epileptic.

Such is the prognosis and course of cerebro-spinal meningitis. The convalescence is usually very slow, and requires just as careful medical attendance as the acute stage of the disease.

Treatment.—The general treatment of cerebro-spinal meningitis was till perhaps the last decade more or less antiphlogistic. Quantities of blood were taken, either by the lancet, the cup, or the leech. Even in our own days there are still some physicians who cannot treat cerebro-spinal meningitis but with a cup or a leech. The same may be said of the application of mustard-poultices to the neck, or of cantharides-plasters to the occiput. As for myself, I never found them beneficial. The counter-irritation which produced a more or less large blister had no beneficent effect on the disease itself, while the annoyance produced by the irritation was of harmful consequence to the patient. Further, nearly in all cases where cantharides were employed dysuria took place, and the patient underwent regular torments as often as he was obliged to urinate.

How far the use of drastic purgatives or large doses of salts are of benefit I cannot say, for I never employed them, as, considering the debilitating state of the febrile process itself, I did not consider them pathologically applicable to such cases.

Till the year 1879 I tried in many cases the above-mentioned treatment, complicating it with the use of cold or hot cloths on the head, and internal administration of quinine and other antipyretics. But I must say that the success that followed such a treatment was nearly *nil*.

It was in 1879 that cerebro-spinal meningitis raged in my neighborhood, and at one time I had about nine cases under treatment. They all were in one house, in a college, where they had been sent for education. The consulting physician was a man of the old

school, thoroughly addicted to the old antiphlogistic treatment, and nothing could convince him that it was wrong both in practice and theory.

At that time I was well acquainted with the fact that morphine, or any form of opium, was highly recommended in the disease, but the gentleman was obdurate and would not listen. The consequence was that eight of our patients died in a comatose condition between the fourth and sixth day of their illness. The ninth of the group was sick the second day at that time, and I had but very little hope that he would pull through. Fortunately, the old doctor became himself unwell, and could not come to see the patient, who from that time on remained entirely in my care. I changed the treatment immediately, stopped the nauseous mixtures of quinine, threw away the cantharides-plaster, and commenced a pure morphine treatment, with plenty of fluid nourishment and cold applications on the head.

The effect was soon visible to all. The patient grew quiet, slept for several hours, day and night, and finally recovered. This single successful case from nine was deeply interesting to me, and I determined to study the effect of morphine in cerebro-spinal meningitis more carefully at the very next opportunity.

This opportunity, however, did not come for many years, till it arrived in the month of January of this year. The case was as follows: S. H., aged 13, male, son of healthy parents, was taken sick one Sunday evening with pain in his head, vomiting, pain in his limbs, considerable tenderness in the hepatic and stomachic region. There was also constipation for two or three days. The conjunctiva slightly yellow, also the tongue covered with yellowish white fur; slight moist râles observed on the chest; no cough; temperature 100°; pulse 96 per minute; urine normal. A compound cathartic was administered, consisting of hydrarg. chlor. mit., jalap, ipecac, and colocynth, which was followed by two or three copious evacuations of dark greenish color and sickening smell. After these evacuations his head seemed a little relieved, and the vomiting was for a time arrested.

The following night, about two hours after midnight, the pain returned again with increased violence, and the frequent vomiting seemed to torment the boy to the utmost. External applications of menthol, camphor, Hoffman's anodyne were tried, but without any benefit. The face became flushed, the pupils dilated and sparkling, the hands and

feet burning hot and dry. About every twenty minutes he screamed from pain with such force that he was heard all over the house. The restlessness continued, and became more violent as time went on, the screams became more frequent, and he finally fell into convulsions, so that three men were necessary to hold him in bed.

As I had been but recently introduced into the family, I called a consultation, which ended in the application of an anal injection of hydrate of chloral. However, the effect of the drug was but of short duration, hence I proposed to make an injection of $\frac{1}{2}$ grain of sulph. morph. hypodermically. This was done, and soon afterwards the patient fell into a quiet sleep. Meanwhile, ice-cold applications were made on the head day and night. Till that time no positive diagnosis was made, yet my experience from the previous cases mentioned inclined me very much to suspect either an encephalitis or cerebro-spinal meningitis.

During the whole time the pulse was hardly more than 90, the temperature 100° or 101° .

On the night of the third to the fourth day the patient was very restless, so that several injections were necessary to keep him quiet. On the same day the characteristic sign of cerebro-spinal meningitis appeared, and my previous suspicions were confirmed.

As soon as the diagnosis was established I determined to rely exclusively on morphine, if no extraordinary circumstances should call for other treatment. As the vomiting still continued, the drug was given hypodermically, and rectal alimentation begun. Every three hours an injection was made in the stomachic region, and every four hours a two-ounce syringe filled with Carnrick's beef peptonoids injected into the rectum.

The following observations were made at that time (January 26):

Time.	Temperature.	Pulse.	Note.
12 M. injection.	101°	96	Restless.
12½ P.M.	$99\frac{1}{10}^{\circ}$	90	Quiet; sleeping.
2 P.M.	$99\frac{1}{10}^{\circ}$	89	Little moaning.
2½ P.M.	$99\frac{1}{10}^{\circ}$	91	Little restless.
2¾ P.M.	$100\frac{1}{10}^{\circ}$	97	Very restless; moaning.
3 P.M. injection.	101°	100	Very restless; moaning.
3½ P.M.	$99\frac{1}{10}^{\circ}$	90	Quiet; not entirely.
4 P.M.	99°	88	Very quiet; sleeping.
5 P.M.	$99\frac{1}{10}^{\circ}$	88	Quiet.
5½ P.M.	$99\frac{1}{10}^{\circ}$	92	Restless.
5¾ P.M.	$100\frac{1}{10}^{\circ}$	94	Very restless.
6 P.M. injection.	$100\frac{1}{10}^{\circ}$	98	Very restless.

This table shows how the morphine injections affected the patient. About one-half or three-quarters of an hour after the injection the boy became quiet, and when not sleeping he was able to understand every word that was spoken in the room. A clear example, or rather confirmation of this assertion, happened that very day. The Catholic priest, who had given him the sacraments, asked me in regard to the prognosis. As the parents of the boy were in the room, I answered him in Latin, to which the priest answered in the same language. He did not mind the boy, as we thought him asleep. In the evening some conversation was started, in which something was said about Latin. At once, quite unexpectedly to us all, the sick boy said, "The priest and the doctor spoke Latin this morning." This one fact speaks for the use of the drug as it was applied.

The treatment was continued in the same manner till the fifth day, when I determined to have the patient's head shaved, and applied a cap of oil-silk, after having had rubbed into the occipital region of his head a portion of a ten per cent. iodoform ointment.

The next few days the restlessness, which usually appeared about two and one-half hours after the injection of morphine, did not come till nearly three and one-half hours had passed. The vomiting was stopped also. Henceforth the drug was given by the mouth in a watery mixture, to which an equal quantity of caffeine was added. A teaspoonful was given every four hours.

The seventh day the time was prolonged to five hours, and on the eighth day none was given during daytime, and only one dose during night.

From that night real convalescence began.

Besides this case I had two more cases of the same disease, which, treated in the same way, ended also in convalescence.

Dr. Timermann, of Huntersville, had at the same time some cases on hand which were treated also with morphine, yet, as I hear that gelsemium and other drugs were used, I cannot say how much of the good effect was derived from the action of morphine and how much from gelsemium.

As for myself, I neither tried ergot nor gelsemium, but morphine alone, hence the result must be put to the account of that drug. The pathological anatomy of cerebro-spinal meningitis I omitted purposely, as being well known to every educated physician.

*A CASE OF CHANCROID SUCCESSFULLY
TREATED WITH MERCURY.*

BY C. L. DODGE, M.D., KINGSTON, N. Y.

I WAS consulted in April, 1886, by Mr. A. He had contracted a venereal ulcer a few days before, which was situated on the prepuce, and which I unhesitatingly pronounced a chancroid. I treated it in the usual way. First gave him a prescription of calomel and oxide of zinc, equal parts of each, to dust on the sore, with a small piece of lint to cover it, the foreskin then being drawn forward. This was continued for several days with no improvement, the sore, on the contrary, enlarging and becoming more painful. I then made a solution of iodoform in ether, and directed him to paint it carefully with a camel's-hair brush. This he tried for several days without any better result. I then told him if he would put up with the odor of iodoform I would give him some of the pure drug, which I felt confident would soon bring about a change for the better. Much to my surprise and the great annoyance of the patient, this seemed to have no better effect than the solution. After continuing for a reasonable time, I at last used a solution of nitrate of silver, twenty grains to the ounce, the ulcer meanwhile spreading and enlarging, and becoming more painful every day. After using the nitrate of silver for three days without any improvement whatever, it occurred to me that possibly I might have been mistaken in my diagnosis, and might have a true chancre to deal with. I then gave him 5 grains of hydrarg. cum creta three times a day. In less than a week the sore began to improve, and I congratulated him on the fine appearance it then presented, and told him he need not return for a few days to come, as it was doing so nicely. Two days later he met me on the street, and told me he had a sore mouth. Without stopping to inquire further, I at once took it for granted that it was owing to the use of the mercury; and I then told him to discontinue taking the powders, and gave him a prescription for a solution of chlorate of potassium as a mouth-wash. He returned in a few days, and told me that his mouth was all right, but the sore was almost as bad as ever. Upon inspection this proved to be true. I now carefully inquired as to the sore mouth, if there had been a bad taste, sore teeth, and an excessive flow of saliva. He then told me that none of these symptoms were present, but he had a broken back tooth,

which he thought had caused the trouble in the side of his cheek, and this proved to be the fact. He went to a dentist, had it properly treated, after which he had no more sore mouth. I now immediately resumed the mercury, and in a few days improvement was evident. The treatment was continued for three weeks, and at the end of that time the sore was completely healed, and gave no further trouble. I now supposed I had a case of syphilis, and had been mistaken in my diagnosis of chancroid. Here was a case presenting a single sore, with no induration of base, however, secretion quite profuse and purulent, and causing a good deal of pain. There were no enlarged ganglia at any time, as I took particular pains to determine positively. Now, this man has been under my observation from that time to the present,—fifteen months. I see him every day, and he has never had any of the secondary symptoms of syphilis, and is to-day a well man. Now, what was this case, chancre or chancroid? I am firmly convinced that it was chancroid. Bumstead* says, "In my own practice I have learned to regard the appearance of secondary symptoms between the fortieth and fiftieth day after the development of the chancre as almost certain, and I have never seen a case which was carefully watched in which they failed to show themselves within three months. Ricord's limit of 'six months' will certainly include the most extreme cases." If this had been a true chancre secondary symptoms ought certainly to have shown themselves long before this. No one would presume to say that he was *cured* of *syphilis* by 5-grain doses of mercury with chalk in three weeks, so I think I am warranted by the facts in affirming this to be a case of chancroid, as I first believed it to be. Now, mercury is said to be always useless and in most cases injurious in chancroid. Under treatment of chancroid Bumstead† says, "The internal use of mercury has no beneficial influence whatever upon the chancroid, which continues in a state of stubborn persistency, or even progresses, after the system is fully under the influence of this mineral. This statement is not a mere inference from the distinct nature of the chancroid and syphilis, but is founded upon experience. I was fully convinced of the fact by personal observation, and ceased to employ mercury for 'soft chancres' several years before the distinction between the two species was recognized. Since abandoning it in my own practice I have had

* "Venereal Diseases," p. 438. † Ibid., p. 365.

numerous opportunities of observing other surgeons administer mercurials for the chancre, and my former opinion has only been confirmed." Authorities are pretty well agreed as to the impropriety of administering mercury in the so-called "soft chancre." In this instance I was led to the use of it from a belief that it might be the true infecting sore, and well knowing the almost marvellous effect that mercury often has upon rebellious chancres, I prescribed it here. Believing this case to be unique, I have recorded it for what it may be worth.

POISONOUS SYMPTOMS FROM NITRO-GLYCERIN.

BY J. NOER, M.D., STOUGHTON, WIS.

ON November 14, 1886, I was called to see Mrs. O. S., age 47. I found her in bed, propped up with pillows into a semi-recumbent position. Face was very pale, and general appearance indicated great prostration and dejection; skin was cold, and covered with a clammy sweat. Breathing slow and heavy. Pulse tense, rather slow (50 to 65), and irregularly intermittent. For a short time it would intermit regularly every third beat, and then it would beat regularly for twenty to fifty beats, when the heart would suddenly stop for a second or two and then start again to repeat the irregular pulse as before. Temperature in the mouth was 99½° F. Pupils dilated, urine scanty, very dark in color, and passed with a great deal of pain and tenesmus at the neck of the bladder apparently. A hasty examination of the urine gave the following results: reaction neutral; sp. gr. 1030; large deposits of solids, principally urates and phosphates. Heller's test gave a very copious deposit of blood-pigments in a test-tube. Auscultation of the heart revealed a peculiar loud booming, seemingly distant, sound, synchronous with the ventricular systole, masking almost entirely the second sound of the heart, while the ventricular contraction appeared to be greatly prolonged. The area of the apex-beat was greatly increased, while the sounds in the aortic region were almost entirely inaudible.

The patient complained a great deal of the pain in the region of the heart, which she said was sharp and intense. There was intense headache, with hammering sensation in the temporal region, and a constricting band round the forehead. There was also great

weakness and muscular prostration. These symptoms, she stated, had been present for about three days.

I was at first unable to decide as to what to attribute these signs and symptoms; but finally I concluded that they must be due to the action of some poison. I soon ascertained that my patient was an old asthmatic, and that she had about three weeks previous to my visit consulted an eminent European physician, who was at that time sojourning in a neighboring city. After examining the mixtures which she was taking, and reflecting upon the symptoms that they had evidently caused, I concluded that nitro-glycerin might very probably be the offending ingredient. I directed the patient to take no more of my predecessor's medicines, and prescribed Tonquin musk, gr. vi, in suppositories, to be used every third hour; strychnine sulphate, gr. ⅓, four times a day; pot. iodide, gr. v, in solution after meals. In a few days patient expressed herself as quite recovered. Pulse was, however, intermittent, and urine contained traces of blood for over a week after my first visit.

Upon investigation I found that Mrs. S. had been taking the following mixtures for two weeks:

R Sol. nitro-glycerin. alcoholic., 30.
Sig.—Ten drops night and morning.

R Decoc. lichen. island., 25-250;
Pot. iodidi, 15;
Pulv. Doveri, 5. M.

Sig.—One tablespoonful after each meal.

R Fumigatoires pectorales (Français), 1 box.

It is evident that the nitro-glycerin solution was the cause of the trouble with Mrs. S. The directed dose of 10 drops had not been taken till a few days before I saw the patient, she having begun with a dose of 3 drops, and increased to 8 drops, which dose had been taken for some time. The 10-drop dose had been taken only a few times.

I think the physician may be open to criticism in this case, first, for prescribing a large and very uncertain dose (drops from a vial) of a dangerous, uncertain, and almost untried remedy to a patient that he never expected to see again; and, secondly, for not warning his patient of the danger. His dose is a very large one, and I believe the patient stated that she had been cautioned by the druggist.

New and dangerous therapeutic agents ought not to be used by travelling physicians nor by any physician who cannot see his patient frequently. I could in this case have helped my learned countryman into a very

disagreeable malpractice suit had I been so disposed. These can, however, bring nothing but disgrace to the medical profession, however much glory and cheap notoriety they may bring to the instigator.

*CARBOLIC ACID POISONING FROM THE
USE OF CARBOLATED COTTON
WITH A CHILD.*

DR. JULES SIMON reports the following case in *Revue Mensuelle des Maladies de l'Enfance*:

A little girl, aged 22 months, had a swelling of the submaxillary glands, for which tincture of iodine was applied, but, unfortunately, so strong that its escharotic effect was produced, and an ulcerated surface was formed. This was dressed with iodoform gauze and also carbolic acid wadding. Twenty-four hours after the first dressing the child was restless, complaining of pain in the head; the throat dry; the conjunctivæ injected; and coryza was present. The temperature was slightly raised, and the pulse very frequent.

The physician in attendance, fearing iodoform-poisoning, removed the iodoform gauze, but continued the carbolic dressing, and added borated cotton to the dressing.

Forty-eight hours after the first dressing the child was taken with uncontrollable emesis, prostration, and anuria; the carbolic acid dressing was then removed.

Great improvement followed in twelve hours, and in twenty-four hours the child was convalescent. The beginning of improvement was marked by the passage of a considerable quantity of urine almost black; the urine increased steadily in quantity, and became quickly normal. The fact that the urine gave no reaction for iodine showed that the poisoning was not due to that agent, while all the symptoms pointed to carbolic acid as the toxic agent.

CALCIUM GUMMOPHOSPHATE.

The administration of compounds such as those known under the names "lactophosphate," "chlorhydrophosphate," and "citrophosphate of lime" is criticised by DR. SAMBUC (*Journ. Pharm.*, April 15, p. 411) on the ground that it is an error to consider them to be soluble double salts in which the phosphate employed retains its primitive condition in the presence of the added acid. On the

contrary, Dr. Sambuc states that the phosphate is decomposed, whether it be dicalcic or tricalcic, monocalcic phosphate being formed, together with calcium lactate, chloride, or citrate, as the case may be. If this be correct, the patient, in order to take one gramme of the monocalcic phosphate, would have to swallow also one-half gramme of calcium chloride or a corresponding quantity of one of the other salts,—a proportion that, considering the freedom with which these preparations are sometimes taken, can hardly be desirable. In order to meet this objection, Dr. Sambuc proposes to use gummic acid, obtained by decomposing Senegal gum with hydrochloric acid and separating by dialysis, and states that when this is added to freshly-prepared dicalcic phosphate it combines with part of the lime, soluble monocalcic phosphate being formed, together with calcium gummate, which, being practically a regeneration of the gum, is not objectionable. As ordinary gum contains, in combination with gummic acid, lime, potash, and magnesia equal to about 1.75 per cent. calculated as calcic oxide, one hundred grammes should, according to this theory, be equal to the solution of ten grammes of dicalcic phosphate. But, in addition to this, it has been shown by Messrs. Lefort and Thibaut that natural gum arabic will dissolve 1 to 1.1 per cent. of bicalcic phosphate, possibly in consequence of the presence of some gummic acid not in combination, so that the total solvent power may be somewhat greater.—*Pharmaceutical Journal and Transactions*, April 30, 1887.

TREATMENT OF ARTERIO-SCLEROSIS.

HUCHARD recommends the following:

R Aquæ destill., ʒi℥ss;
Potass. iodid., ʒi℥ss;
Ext. aqueos. opii, gr. iss.

Dose.—2 to 3 teaspoonfuls daily.

When bronchitic complications are added the following may be used:

R Aquæ destill., ʒi℥ss;
Potass. iodid., ʒi℥ss;
Tinct. senegæ, ʒi℥ss;
Tinct. lobeliæ, ʒi℥ss;
Ext. aqueos. opii, gr. iss.

Two or three teaspoonfuls daily.

—*Les Nouveaux Remèdes*, No. 8.

Leading Articles.

THE IODOFORM QUESTION.

ONE would think that iodoform had been long enough before the medical public to have thoroughly established its status. Nevertheless, in many points we find the greatest diversity of opinion as to the value or even harmlessness of this remedy. On no point, perhaps, is there greater uncertainty than as regards the local application of iodoform in the treatment of tubercular deposits.

If the literature of this subject is examined we will find on the one hand numerous authors denying totally any special action of iodoform on the tubercular process; others, while perhaps admitting a favorable influence in preventing the return of the disease after total excision of the tubercular tissue, limit the action of iodoform to this alone. It is evident that if we restrict the value of iodoform to such cases as these its action cannot be regarded as specific, but merely as assisting the primary healing of the wound. On the other hand, a number of authors, led by Mosetig-Moorhof, go so far as not only to attribute specific antitubercular action from direct contact of iodoform, but even attribute to the

odor of this drug specific antitubercular properties. This contradiction is without doubt attributable to the great difficulty attending any thorough application of this drug. As an illustration of this we need only recall that the failure to heal, often seen in the treatment of tubercular ulcers and fistulæ from the application of iodoform, is not to be attributed to the lack of action of this drug, but to the difficulty in procuring thorough contact between it and all the various tortuous passages of the fistulæ.

Considerable light has been thrown on this subject by a communication published by Prof. Bruns in the *Therapeutische Monatshefte* for May, 1887. He calls attention to the fact that the progress of cold tubercular abscesses treated by means of iodoform injections should offer conclusive proof as to the value or worthlessness of iodoform. He relates the progress of fifty cases treated in this manner in his clinic. The method of treatment was to aspirate the abscess under antiseptic precautions, and then to inject through the aspirator-needle a ten per cent. mixture of iodoform, with equal parts of glycerin and alcohol, and to close the opening by means of iodoform collodium. His general experience was that this operation was followed by no local or general reaction, with the exception of a single instance where slight symptoms of iodoform-poisoning were observed. As a rule, in small abscesses a single injection serves to produce cure and gradual disappearance of the disease within one to two months. Generally, however, two to three injections were necessary, which were performed at intervals of three or four weeks. In such cases several months were required for cure, and in several cases a fistula formed to the abscess. This, however, Prof. Bruns does not regard as a serious complication, since the abscess evacuates itself through this fistula, and ultimately heals. Of the fifty-four cases which were treated by this manner forty were healed, and among them a number of abscesses from which between five hundred to one thousand grammes of pus were evacuated.

When one thinks how extremely difficult it is to obtain a cure of cold abscesses by any method, this large percentage of cures is very striking, and when it is further remembered that a tubercular abscess membrane and often tubercular bone remains behind, it seems almost warrantable to attribute with the author to iodoform a specific antitubercular action, for it is evident that the action of the iodoform does not depend either upon caustic de-

struction of the tubercular tissue or through exciting a sufficiently strong inflammatory process to accomplish its removal. It seems therefore warrantable to attribute the results to the prolonged and close contact of the iodoform with the inner wall of the abscess and of the consequent destruction of the tubercular tissue. To obtain some light as to the exact method in which the iodoform produced its action, Prof. Bruns opened a number of cold abscesses at different intervals after the injection of iodoform, and partly or totally extirpated their walls in eight cases, whose tubercular nature was clearly proved, and subjected them to microscopic examination. While no full details of the examination are given, Prof. Bruns states that the first change which follows as a result of the iodoform treatment is the disappearance within a few weeks of the tubercular bacilli from the walls of the abscess, while the characteristics of tubercular tissue give place to normal granulation-tissue. He therefore attributes the cure to the destruction of the bacilli through the application of iodoform.

ANTIPYRETICS.

AT a recent meeting of the Association of American Physicians the subject of antipyretic administration was discussed *in extenso*.

In opening the discussion, Dr. H. C. Wood advanced the following propositions:

First.—Fever is a disturbance of calorification in which, through the nervous system, heat-dissipation and heat-production are both affected. If there be a fever which is produced by a direct action of a poison independently of the nervous system, we have at present no proof of its existence.

Second.—That heat-production is regulated by a nervous apparatus, our knowledge of which is still imperfect. There is certainly an inhibitory centre which depresses or controls the production of heat. It probably does this by acting on the trophic cells of the gray matter of the spinal cord. It is also probable that there is a centre which when excited increases tissue-change, but its existence has not been absolutely proven.

Third.—Heat-dissipation is regulated through the vaso-motor nerves, so that vaso-motor paralysis is followed by an enormous loss of animal heat, and under unfavorable circumstances by death from cold.

Fourth.—Drugs may lower bodily temperature in health or in fever by increasing heat-dissipation.

The facts which he stated as demonstrating the truth of these propositions appeared to be accepted by all the members present as definite and positive, excepting in that Professor Welch, of Johns Hopkins University, stated that he believed that the experiments of Aronsohn and Sachs had established the existence of accelerator heat-nerves, and after the discussion Dr. Wood acquiesced in this.

Almost all the physicians who took part in the discussion were in accord in believing that the modern antipyretics, such as antipyrin and antifebrin, are in most cases of fever efficacious in reducing temperature, and that when properly used they do not affect the general strength or the force of the circulation; and whilst they are entirely devoid of any power in controlling the course of specific fever, they often do good by quieting the pain, promoting sleep, and overcoming restlessness through the reduction of temperature.

Almost all the speakers who claimed to have experience with the cold bath appeared to believe that its action was more favorable than was that of the antipyretic remedy. It was suggested by Dr. Wood that the cold bath, acting as a powerful stimulant to the immense mass of the peripheral nerves which reach the surface of the body, probably has an action on the organism apart from the mere obstruction of heat, and that it may be much of its soothing influence is the result of this peripheral stimulation.

The difficulties which surround the use of water as an external refrigerator agent are such that, at least in this country, most practitioners will probably prefer antipyretic drugs, although the latter are probably of inferior value.

Dr. John Guit  ras, who practised for a long time in the extreme southern parts of the United States, stated as the result of large experience that in the long-continued fevers of those sections antipyrin, whilst capable of producing a temporary influence, had no power in controlling the disease, and often seemed to lose its influence; that in a very large proportion of cases in which he had been called in consultation the best results were achieved by withdrawing the antipyretic and substituting the cold bath, which seemed not only to temporarily affect the fever, but to have some influence in subduing the disease.

DIARRHŒA OF CHILDREN.

AS the season of the year approaches in which diarrhœas are especially fatal in children, we feel it not improper to call the attention of our readers to a remedy which, though used by some practitioners, is, we think, still neglected by many of the profession. We refer to the phosphate of sodium. In the summer diarrhœas connected with a lack of digestive power, in which the stools are either clay-colored or habitually greenish, phosphate of sodium often brings a favorable response when the ordinary remedies for diarrhœa seem to irritate rather than do good. In nursing children it may be given in the milk, 10 grains of it in each bottle, or it may be given after eating, dissolved in a little water. It should be administered always in repeated small doses and not in a single large dose. Where there is habitual constipation, with occasional attacks of diarrhœa in young children, it is especially serviceable. It probably has some distinct specific action upon the glandular organs of the intestinal tract.

Another treatment of diarrhœa to which we want to direct the reader's attention anew, is the use of the cold bath. Our own experience has convinced us of the truth of the original affirmation of Dr. Comegys, of Cincinnati, that in the diarrhœas occurring in young children in intensely hot weather with more or less pronounced elevation of the bodily temperature, the cold bath will often suffice for a cure, and will often bring relief when all other measures fail. It should be given as often as the child's temperature rises; in rare cases once in every three hours. In other cases two or three times a day. The water should be of a temperature not above 80°, and the immersion should be sufficiently long to produce a distinct effect. Properly managed, these cold baths we think of inestimable value in the treatment of those forms of summer infantile diarrhœa which are the outcome of heat.

GASTRIC ULCER.

ULCER of the stomach is probably a much more frequent disorder than is generally recognized. On the other hand it probably is often believed to exist when not present. Our own experience has led us to think that the positive diagnosis as to its existence or non-existence is in some cases impossible. It may be simulated by chronic gastric catarrh

or by neurosis of the stomach. Pain after eating, with vomiting, and great epigastric tenderness are very common in hysterical women, especially in girls shortly after puberty. The absence of blood from the vomit is not of as much importance from a diagnostic point of view as appears at first sight. Hysterical vomiting is not rarely accompanied by slight or even more pronounced hæmatemesis, and we have seen fatal ulcer of the stomach without hemorrhage, and, indeed, without any history of vomiting. Gastric ulcer is of course not infrequent in young hysterical girls, but that the gastric symptoms are often not due to any stomachic ulceration is proven by their occasional sudden disappearance.

Our own experience is that in many of these neurotic cases a quarter of a grain of nitrate of silver with a grain of hyoscyamus, accompanied by soft diet, is efficacious. If, however, it fail to do good in the course of a very few weeks, its use should be abandoned, and the treatment be that of hysteria, with a use of diluted nitro-muriatic acid at meals.

In a recent article in the *Medical Press* Dr. W. H. Pearce calls attention to the fact that many of these cases do best when their eccentricities of diet are given full swing. If the patient prefers smoked and salt fish, salt meats, pickles, onions, or even Dutch cheese, he allows the article to be taken with asserted good results. A favorite article with him seems to be one which is not much used by the Anglo-Saxon race in America, namely, "potatoes with vinegar." Whether by this is meant the potato salad beloved by our German brethren or not, we do not know.

"DRUMINE."

UNDER this title our readers will recollect that we called attention to what was claimed to be an alkaloid found in *Euphorbia Drummondii* by Dr. John Reid, of Melbourne.

In the notices in which we called attention to this alleged discovery we expressed ourselves as doubting the accuracy of Dr. Reid's statements, and alluded to the entire failure at the hands of Dr. Ogsdon, experimenting with the article obtained directly from Dr. Reid, to obtain any anæsthetic properties whatever.

From articles published in the *Pharmaceutical Journal and Transactions* for June 18, 1887, we learn that our scepticism is supported by a similar failure in the hands of Mr. W. H. H. Jessup, who tested the article

also procured directly from Dr. Reid both by injecting subcutaneously and when applied to the eye, with absolutely negative results. Chemical examination also showed that the solution gave no indication of the presence of any alkaloid. In the same number of the *Pharmaceutical Journal and Transactions* is a letter from Mr. Tanner, who found that the so-called alkaloid was entirely insoluble in water, dilute acetic acid, alcohol, ether, and chloroform, but soluble in dilute hydrochloric acid, from which it was reprecipitated on the addition of ammonia in excess. The hydrochloric solution gave no precipitate with the usual tests for alkaloids, and when gently ignited on platinum foil but little charring took place, and a considerable grayish residue, soluble with effervescence in hydrochloric acid, and answering in characters and tests to calcium carbonate, was obtained. It afforded no indication of the presence of nitrogen. Mr. Tanner advances further proof to show that the substance supplied under the name of "drumine" consists mainly of calcium oxalate. It would, therefore, appear that if an alkaloid is present in the plant operated on by Dr. Reid, his method of extraction fails in obtaining it, while it is well calculated to furnish nothing more than calcium oxalate. It might also be added that the agents selected by Dr. Reid for the supply of this so-called alkaloid having found it "unsatisfactory," have declined any further supply of the article at present.

Reports on Therapeutic Progress.

AN EXPERIMENTAL STUDY OF THE EFFECTS OF PUNCTURE OF THE HEART IN CASES OF CHLOROFORM NARCOSIS.

At a recent meeting of the Medical Society of the District of Columbia Dr. B. A. WATSON, of Jersey City, read a paper on the above subject.

The results of sixty experiments on dogs were given in detail. The experiments consisted briefly in producing death by chloroform inhalation, and then within from one to three or four minutes an aspirating needle was introduced into the heart through the chest-walls, the attempt being to reach the right ventricle. In the first fifty cases the chloroform was administered rapidly and air was excluded as far as was possible. In the last ten the chloroform was administered slowly, and

with a large proportion of air. The first forty animals had already suffered some severe traumatic injury, while the last twenty were perfectly healthy animals. The punctures made in these sixty experiments were as follows: Right ventricle, 38; left ventricle, 6; right auricle, 6; superior vena cava, 3; inferior vena cava, 2; apex of the heart, 2; and not stated, 1. The resuscitations were as follows: after puncture of the right ventricle, 9; right auricle, 1. The first forty experiments gave only four recoveries, while the last twenty gave six. In only one of the sixty cases did the heart fail to respond to puncture, and in this instance the use of the needle was postponed for four minutes after the cessation of the heart's action, and one minute after breathing had stopped.

Should the puncture be carried into one of the cavities of the heart in order that blood may be abstracted? In chloroform narcosis the heart is found in diastole, and the veins in the lungs are greatly distended with blood. It may therefore theoretically be assumed that blood may be advantageously drawn from the right side of the heart. The author was assured that this procedure was practical and advantageous.

The only deaths during these experiments which could be attributed directly to the puncture were those in which the needle penetrated the vena cava. In these cases there was profuse hemorrhage into the thoracic cavity. Punctures made into the auricle are sometimes followed by a flow of blood into the pericardium. Punctures into the ventricle are not attended with any hemorrhage from the interior of the organ, but there may be a few drops of blood from a wounded cardiac vein.

The following conclusions were reached:

First.—Puncture of the heart, especially of the right ventricle, stimulates muscular contractions, and may be advantageously applied in the treatment of chloroform narcosis.

Secondly.—The best results are obtained when abstraction of blood from the cavity of the ventricle is combined with the stimulating effects produced by the entrance of the aspiratory needle.

Thirdly.—The puncture of the right ventricle is a safer and more efficient operative procedure than the puncture of the right auricle.

In the discussion which followed the reading of this paper Dr. N. P. DANDRIDGE, of Cincinnati, said the conditions under which the experiments were made were different

from those under which accidents usually occur in human beings. In the latter case the accident usually occurs after only a small quantity has been taken, and often early in its administration. The effect is probably due to a reflex effect upon the inhibitory action of the heart. In the experiments reported puncture was resorted to within one or two minutes after the cessation of the heart's action. In the accidents with chloroform it is not uncommon to have recovery after apparent cessation of the heart's action for a comparatively longer period. A large number of experiments are required to test the relative value of this procedure as compared with artificial respiration. The use of nitrite of amyl, and particularly with the subcutaneous injection of atropine, should be resorted to. This latter can always be done quickly, and has a stimulating effect upon the cardiac and respiratory centres.

DR. JOHN B. ROBERTS, of Philadelphia, said that the speaker, while he had shown the comparative innocuousness of the heart with a small needle, had also shown the danger of using chloroform as an anæsthetic in any cases, possibly cases of parturition excepted. His experiments have shown that it is more dangerous to puncture the auricle than the ventricle, which would naturally be suggested by the fact that the auricle has a much thinner wall.

DR. T. J. DUNOTT, of Harrisburg, referred to a case in which the heart was twice punctured with an aspiratory needle, and blood drawn from the cavity of the heart. It was a case of dilatation of the heart with general dropsy, etc. The operation was performed by a homœopathic practitioner, under the idea that he was dealing with a case of dropsy of the pericardium. A large quantity of blood was removed, and for a time there was improvement. The symptoms again returned, and the operation was repeated with a fatal result.—*Journal of the American Medical Association.*

STRETCHING THE SPHINCTER IN APOPLEXY.

In the *Lancet* for May 21, 1887, MR. JOHN W. TEALE reports the case of a lady, aged 64, who suffered greatly from constipation, had had several attacks of what she called angina pectoris, and lived in perpetual dread of having accumulations in the bowels, from which she had suffered. The routine treatment of mild alteratives, tonics, and aperients which Mr. Teale instituted proved a complete

failure. The sphincter was found tightly contracted, and the rectum distended with hardened fæces. In her feeble health, shattered nerves, irritable heart, and albuminous urine, an operation seemed inadmissible. Repeated castor-oil enemata were consequently resorted to, resulting in considerable relief.

About a week later two injections were employed, which proved ineffectual, and she became very restless and excited, and her face commenced to twitch, increasing in violence until these twitchings amounted to violent convulsions. When Mr. Teale reached her he found slight but well-marked symptoms of paralysis of the left side of the face, and which gradually became more decided in character, extending to the left arm and leg; the pupils were regular, somewhat contracted, slightly sensitive to light. There was no stertor, but insensibility was complete. Every few minutes there was a convulsive attack, commencing with twitching on the left side of the face, extending gradually to the left arm and leg, and then becoming general over both sides of the body, and gradually relaxing without pursuing any definite order. On examining, per anum, hardened fæces could be felt floating in enema of soapy water and olive oil, which had been given, though the sphincter was so tightly closed that the finger could only be passed with difficulty. Availing himself of the state of unconsciousness present, Mr. Teale stretched the sphincter freely, and immediately the enema poured out, followed by offensive fæces. The convulsions continued as before; potassium bromide was given by injections and retained, and the urine, which became almost solid on boiling, was drawn off by the catheter. Consciousness did not return until the next day. For the next three or four days the urine had to be drawn off by the catheter. The amount of albumen soon became merely nominal. The patient slowly recovered.

For some days she misplaced names and words. The right side of the body soon regained power, the left more slowly, but remained markedly weaker than the right. In about three weeks she returned home, the bowels then acting easily and naturally without purgatives.

A year later the patient died. The writer thinks the operation lengthened her life for nearly a year, and also relieved her from suffering. The fact that prolonged constipation from any cause is an important factor in causing apoplexy, when the arterial coats are

dégenerated, has long been recognized,—an argument, no doubt, for the early and effectual surgical relief of affections of the rectum, where they are found to exist.

COMPOSITION OF COW'S MILK.

The results of an experiment made primarily to determine the variations in the proportion of phosphoric acid occurring in the milk of the cow have been recorded by M. ANDOUARD (*Comptes-Rendus*, civ. 1298). The experiment was made on four cows, one of which was fed on pasturage, with the necessary complement of hay and bran, while the others were fed with beets, swedes, potatoes, legumes, etc. It was found that the phosphoric acid in the milk underwent a progressive diminution during the period of lactation extending to 10.46 per cent. on the initial weight in the case of the cow fed on pasturage, and ranging from 14.91 per cent. to 45.39 per cent. on the initial weight in the cases of those fed on roots, etc. It was also observed among other things that the butter, and especially the sugar, also diminished in quantity during the same period, whilst with respect to casein the milk from two of the cows contained an increasing proportion, while that from the other two contained a decreasing proportion. The paper does not contain any statements of absolute quantities.—*The Pharmaceutical Journal and Transactions*, May 28, 1887.

SOME POINTS IN THE SELECTION AND ADMINISTRATION OF ANÆSTHETICS.

At a meeting of the West London Medico-Chirurgical Society, held May 6, DR. HEWITT read a paper upon the above subject, and said that he wished to limit his remarks to the consideration of the following points: 1. The best method of administering nitrous oxide and ether, either in succession or in combination. 2. The prevention of vomiting during or after the administration of an anæsthetic. 3. The danger of inducing general anæsthesia in persons so suffering from obstructive dyspnoea. 4. The possibility of dangerous symptoms occurring from the administration of opium or morphine prior to chloroform, ether, or other anæsthetics. He exhibited an apparatus which he had used for three years in hospital and private practice. It consisted of a Clover's portable ether-inhaler fitted with a special form of face-piece, and with a bag capable of holding two gallons of gas. By

means of this apparatus any desired combination of nitrous oxide and ether could be given. The amount of gas in the bag was always sufficient, when administered with the face-piece shown, to anæsthetize a patient before gradually admixing the ether vapor; and the whole apparatus was portable, and could be changed before entering the room in which the operation was to be performed. By means of this apparatus there was no sudden transition from nitrous oxide to ether, as when face-pieces were changed during the administration. Vomiting could be prevented by rapid and deep anæsthesia. In a large number of cases he had given a half-grain of cocaine in half an ounce of water shortly before the administration of an anæsthetic. This was done with the object of lessening the sensibility of the gastric mucous membrane. Vomiting after anæsthetics was best prevented by keeping the patient upon his side, and by moving him as little as possible. The danger of inducing anæsthetic sleep in persons suffering from obstructive dyspnoea was then considered. Patients in this condition were dependent for their existence upon an increased activity of their respiratory mechanism, and failure of respiration was very likely to ensue under chloroform or ether.—*The Lancet*, May 28, 1887.

PHYSIOLOGICAL ACTION OF REMIJIA FERRUGINEA.

According to the Paris correspondent of the *British Medical Journal*, June 4, 1887, at a recent meeting of the Biological Society MM. PINET and DUPRAT communicated a note on the physiological action of *remijia ferruginea*. The preparations employed in the experiments were a watery and a hydro-alcoholic extract of the root of the plant. Both extracts, when tested with litmus-paper, showed a decided acid reaction. The hydro-alcoholic was much less active than the watery extract. The experiments were made on frogs weighing thirty grammes, and the dose was the quantity contained in three divisions out of twenty in a Pravaz syringe. A quarter of an hour after an injection into one of the hind feet, the animal was found to show general hyperexcitability, with considerable increase of respiratory movement and of cardiac pulsation. In some of the animals the energy of the ventricular contraction was so great as to produce asphyxia, which continued throughout the entire duration of the intoxication. The heart was found to be abnor-

mally red. The electrical contractility of the muscles remained intact. Ligature of the iliac artery on one side, with injection of the extract into the opposite limb, produced no difference in the result. Section of the lumbar nerves on one side, with injection into the opposite limb, caused convulsions only on the side on which the innervation remained intact. When the spinal cord was divided below the medulla, no convulsive action took place. Ablation of the cerebral hemispheres in no way affected the phenomena above described. MM. Pinet and Duprat conclude that *remijia ferruginea* acts chiefly on the medulla.

BERGEON'S METHOD OF TREATING PHTHISIS.

At a recent meeting of the Association of American Physicians Dr. E. T. BRUEN read a paper on the above subject, in which he stated that since February last he had employed Bergeon's method of treatment in sixty-one cases. Forty-four of these cases had been benefited, but of these only three appeared to regain full health. Two of these were cases of incipient phthisis, with apparent consolidation of the apex of the right lung. In one of these cases the bacillus tuberculosis was not found, although five examinations were made. In the other case the bacillus was found. In these cases the apparent recovery had been associated with a decided increase in weight. He believed, however, that the disease was simply latent. The third case was one of broncho-pneumonia. In all the other cases the lesions were more or less advanced, with the presence of cavities and profuse expectoration. In the fifteen cases in which a negative result was obtained the treatment in some was followed by temporary benefit. The good results had consisted in lessening of the expectoration, diminution of the cough, lowering of the temperature, and suspending of the night-sweats. In most of the cases there was a diminution of from fifteen to twenty beats in the pulse, and a diminution of half a degree in the temperature during the administration of the gas. Even in those cases which were benefited, and in which the temperature had been brought to normal, there would be during the progress of the treatment occasional outbreaks, with a return of the fever and the other symptoms. These, however, disappeared under a continuance of the injections. In order to determine the effect of the treatment on the bacilli, Dr. E. O. Shakespeare made a number of examina-

tions during the progress of the cases. There had been no diminution in the number of the bacilli. It was, however, thought that in those cases where the treatment had been continued for some time the reaction of the bacilli to the staining fluid was less marked.

Two cases had died. In one of these an autopsy was made. This case had been under treatment for two months. The walls of the cavity were moderately smooth and firm, but there was no tendency to cicatrization. The results were of a decidedly negative character.

In most of the cases a solution made by the addition of five grains each of sodium sulphide and sodium chloride to a pint and a half of water was the solution employed. In some cases the strength of the solution had been gradually increased, but where no benefit had been obtained from the weak solution the stronger solution did not act with any better results. In cases of diarrhoea his experience had been unfavorable, except where the gas was given in very small quantities. Chronic peritonitis was a contraindication to the use of this plan of treatment. In about one case in every ten he had observed the reaction of sulphuretted hydrogen when a paper treated with acetate of lead had been applied to the mouth.

Bergeon's method is chiefly valuable in those cases attended with bronchial catarrh. He had had very little good effect in those cases where there was thickening of the lung without much catarrh. The speaker feared that the trouble and detail necessary to the successful application of this method and the limitations of its power would cause it to be set aside for other therapeutic measures.

DR. F. C. SHATTUCK, of Boston, also presented some clinical notes on the same subject. The speaker had treated only seven cases by this method. They were in an advanced stage of the disease. He had seen such improvement follow careful dietetic and hygienic management that he had not much confidence in the results claimed for special methods of treatment in these cases. Any new method of treatment will often have an apparently beneficial effect through its influence on the mind even in those cases which are incurable. Six of the cases treated suffered with phthisis, and five were in an advanced stage of the disease. One was a case of chronic bronchitis with asthma and emphysema. Four of the patients suffered with more or less pronounced collapse from the use of the injections. Nausea, vomiting, and diarrhoea oc-

curred in several cases. In one case, although the patient was weak, no local or general ill effect was observed. In another case the treatment was continued four weeks with no ill effect. The only benefit obtained was a diminution of the expectoration. In the case of asthma and chronic bronchitis, thirty-four enemata were given. The improvement was no more rapid than on a previous occasion when the patient had been treated in the same general way with the exception of the gas. He presented the following conclusions :

1. Toxic symptoms may follow the injection of sulphuretted hydrogen gas ; these are nausea, vomiting, general depression, collapse, and perhaps headache.

2. Strong artificial solutions of sulphuretted hydrogen gas with carbonic-acid gas are apt to cause abdominal discomfort. The risk of this is diminished by heating the solution of the former gas.

3. This is not by any means a specific. If useful at all it is only as an auxiliary to the more usual methods of treatment.

4. The only benefit which we have seen that could be fairly attributed to the enemata was a diminution in the amount of the expectoration.

In conclusion, the author stated that the impression which he had formed was that the good results which had unquestionably followed this method of treatment were attributable in large part to the stimulation induced by the employment of a novel method of treatment which makes the patient feel that something is being done for him.

DR. WILLIAM PEPPER, of Philadelphia, stated that he had, with the assistance of Dr. J. Crozier Griffith, employed this method in twenty-four cases in which the treatment was continued, on an average, twenty-five days. Other treatment was frequently combined with the use of the injections. A daily temperature record was kept in sixteen cases : in four there was more or less reduction ; in eleven there was no appreciable effect ; in one the temperature increased, but this was probably a coincidence. In no case was the temperature brought from a febrile to a continuously normal condition. The fall was not more than is seen in similar cases under other methods of treatment.

In twenty cases in which the weight was recorded there was in eight more or less gain. Eight pounds in thirty-seven days was the greatest gain. In six cases the weight remained stationary, and in six it was diminished.

The improvement in cough was not marked. The expectoration was somewhat diminished in four out of twenty-four cases. Search was made for the bacilli in thirty cases, and they were found in twenty-seven. In eleven cases the examination was repeated, and only in four was there any apparent decrease. Cases of night-sweats were not numerous. In one they were checked and in seven improved. Physical examination showed no improvement in a single case. The enemata had a decided hypnotic influence in three cases. The only unpleasant symptom of any real moment was colic. This was complained of in eleven out of twenty-four cases. Three others suffered so much that the treatment could not be repeated. The colic was not often controlled by giving smaller quantities of the gas, nor did it seem to be influenced by the slowness of the injection. This method of treatment is seldom of real benefit by relieving certain symptoms.

DR. H. C. WOOD, of Philadelphia : After studying the cases treated by this method he came to the conclusion that it was of a certain amount of benefit. He saw that the method of employing the gas presented many objections. The sulphuretted hydrogen should accomplish the same results when absorbed by the stomach as when taken up by the large intestine. He has, therefore, administered the sulphuretted hydrogen gas in carbonic acid water. Water at the ordinary temperature takes up two or three times its volume of sulphuretted hydrogen. He thinks that this is a distinct addition to pulmonary therapeutics. He has tried it in certain cases with benefit.—*The Medical Record*, June 18, 1887.

THE TREATMENT OF SCROFULOUS GLANDS.

All surgeons are familiar with the slowly suppurating cervical and other lymphatic glands occurring in strumous children, which, while tedious and insidious in their course, generally after months or years of suffering end at the best in elevated or depressed cicatrices and unsightly scars. We have already referred to the method introduced by Prof. Verneuil, of the treatment of such conditions by drawing off the pus and injecting an ethereal solution of iodoform. In the *New York Medical Journal* for June 25 is an article by DR. H. C. ROGERS on the subject. He states that he has treated nine cases by this method. The swelling gradually disappeared in from three weeks to two months. The plan

is first to evacuate the pus by aspiration. To do this a large-sized trocar should be employed, handling the parts as little as possible. As soon as the liquid becomes slightly blood-stained the iodoform solution should be injected. Dr. Rogers's experience usually is that one injection will be sufficient, and he employs the injection even where he is unable to find pus, but where the centre of the swelling is soft and in a condition to break down. In such cases his plan is to inject from 10 to 20 minims of a two per cent. solution of iodoform in ether. In addition to the local treatment he employs internal medication, and speaks in the highest terms of the compound syrup of trifolium, which is a mixture containing iodide of potassium combined with the vegetable alteratives, red clover, burdock-root and prickly-ash bark, stillingia, poke-root, and berberis aquifolium, each ounce containing eight grains of iodide of potassium. Together with this Dr. Rogers uses iodide of arsenic, bichloride of mercury, sulphide of calcium or iron, to build up the constitutions. Instead of ether, glycerin may be substituted as a solvent for iodoform, ten parts of iodoform being mixed up with one hundred parts of glycerin.

MOLLIN.

LIEBREICH writes as follows concerning this new substance in the *Therapeutische Monatshefte*, Heft 4:

Under the name mollin we commonly understand a mixture of potassium soap and fat. The name itself does not inform us whether the substance is chemically one, or a mixture of substances of the same sort, or a preparation after a given formula, of ingredients prepared for the physician's use. We have as yet no name precisely describing mollin; we can only describe it as a potassium soap which contains seventeen per cent. of excess of fats, which are the ordinary soap-fat, tallow, and cocoanut oil, to which glycerin is added. The mixture is white and smeary, and strongly alkaline in reaction. This salve is very easily made, for cocoanut oil saponifies very easily when cold, and induces the same process in other fats mixed with it.

Mollin may be prepared as follows: A mixture of 50 parts cocoanut oil and 50 parts lard is treated with a solution of caustic potash, 20 parts potash and 4 water, and allowed to stand an hour. In this time saponification takes place. The mixture may be also warmed. This soapy compound is increased

by the addition of seventeen per cent. of fat, previously melted and refined. The process of saponification is slower and less complete when fat is added when the first mixture of cocoanut oil and lard with the alkali is made. To mollin so made glycerin also may be added. The solid condition of the product is dependent upon the property of the cocoanut oil to harden readily. The process may be carried on without heating if concentrated caustic potash solution is used, a fact familiar to all soapmakers. The suggestion for the manufacture of mollin was given by Unna in his remarks upon soaps containing an excess of fats. The therapeutic uses of mollin will appear as it is used more extensively.

All glycerin fats show a marked tendency to become rancid, especially when mixed with soaps. It is a well-known fact that when any error in the technique of soap manufacture is made, the importance of securing the saponification of all fats is at once evident from the instability shown by soaps containing free fat. The idea that the excess of an alkali can be neutralized by fat is erroneous, for we frequently find soaps which have been kept for years, and yet contain free fat in the presence of free alkali. The combination of the fat contained in a soap with a free alkali can only be properly performed during boiling. Neutralization is only possible when fat is decomposed by the alkali, a process which takes considerable time and a high temperature for its accomplishment. The writer states that he has often previously observed that the free alkali in a soap is extremely hard to neutralize, and that a neutral soap may be best formed by separation by centrifugal force. After the alkalies of a soap have combined, the central mass or real soap will be separated by centrifugal force, and the lye removes in still greater amount the potash and impurities. But this form of manufacture is possible only for sodium soaps. With potassium soaps chlorate of potassium will not combine with the fats, while sodium chloride forms a sodium soap. A good potassium soap then can only be made by the most careful manufacture, and will contain free alkali. It is hardly possible by direct combination to obtain a neutral potassium soap.

In mollin, also, which is a cocoanut oil potassium soap, the free alkali is not entirely neutralized, but by the addition of the excess of fat the action of the alkali is much lessened, both by the reduction of its percentage and by the local protection against its influence

which the fat affords. The choice of cocoa fat is not without detriment. This fat contains more than those of the glycerin series of the lower fatty acids, and a potassium soap made with such fat contains a considerable amount of the salts of these fatty acids. The fact that these substances may exercise an irritating influence upon the skin should lead to caution in preparing and ordering mollin, as the per cent. of fat may be changed at pleasure; the ordinary *sapo kalinus* of the (German) Pharmacopœia may prove a better material for such preparations than cocoa fat.

The following formulæ give useful and well-combined mixtures:

Saponis kalini, 100 parts;

Add

Adipis (melted at gentle heat), 50 or 80 parts;

Glycerini, 10 parts.

The consistence of this mass is not as solid as that of mollin made with cocoa fat.

The greater the amount of soap added in this mixture the more easily will the substance be washed from the skin, and by such removal of the soap under all circumstances the skin will be covered by fat. The danger that mollin will become rancid through the fat added in its preparation suggests the substitution of lanolin for the cocoa fat. The consistence of the resulting mixture is the same. It may be prepared after the following formula:

Saponis kalini, 100 parts;

Lanolini, 50 or 100 parts.

It is extremely useful in many cases in which an alkaline soap cannot be used, to mollify the action of the alkali by the addition of fat. It must, however, be remembered that such soap or ointment has a pungent taste and irritating action, and all who prepare such compounds should be instructed that they are not to be used upon wounds. The same prohibition applies naturally to mucous membrane. The applicability of such caution to mollin is evident when we remember that mollin is a preparation of soap.

We shall reach better and more accurate results and more exact information if those who use mollin will adhere uniformly to the formulæ given, thereby giving a constant basis for judgment.

A NEW AND IMPERVIOUS DRESSING.

Photoxylin, a substance in use among photographers, was recommended some time ago by Dr. Krysiniski as a suitable material

for mounting microscopic specimens, and more recently still it has been utilized by PROF. WAHL, of St. Petersburg, as a substitute for collodion in surgical practice. A five per cent. solution in equal parts of alcohol and ether he finds preferable to collodion, as it adheres more firmly to the skin, not being so easily rubbed off in washing. It is absolutely impervious to liquids, and exerts a perfectly even compression on the tissues. In out-patient practice Prof. Wahl finds that, after small operations, such as the extirpation of glands, the application of photoxylin solution enables him to dispense entirely with voluminous antiseptic dressings; also in plastic operations on the face, and in operations in the neighborhood of the male genital organs, such as those for the radical cure of hernia and castration, where it is very difficult to prevent the urine soaking through antiseptic dressings. Prof. Wahl, after carefully arresting all hemorrhage, closes the wound with sutures and gelatin plaster, and then covers the whole with a thin layer of wool soaked in a solution of photoxylin. This, it is stated, will remain eight or ten days, entirely resisting all the effects of moisture. Even in laparotomy, extensive dressings may, he believes, be dispensed with by painting a solution of photoxylin over the wound with a brush, or by the application of a layer of cotton-wool soaked in the same liquid. Photoxylin appears to be unknown in this country. It was introduced by Messrs. Mann, of St. Petersburg.—*The Lancet*, June 18, 1887.

MECHANISM OF THE THIRD STAGE OF LABOR: THE SEPARATION AND EXPULSION OF THE MEMBRANES.

At a recent meeting of the Obstetrical Society of London DR. F. H. CHAMPNEYS read a paper with this title, part of which has already been laid before the readers of the GAZETTE. The views that had been expressed on the subject amounted to four: 1. The peeling off of the membranes by the traction of the descending placenta. 2. Separation by effusion of blood. 3. Wrinkling of the membranes by uterine contraction and retraction. 4. Separation of the lower pole of the ovum by retraction of the lower uterine segment. The second of these was dismissed on the ground that the quantity of blood lost in an ordinary labor was too small to produce this result, and that, with the usual eccentric implantation of the placenta, this mechanism would fail of its purpose. He

criticised the expression "weight of the placenta," as having influence on the mechanism in the recumbent attitude, and also the expression "leaving (the process) to nature," as applied to its course in the recumbent attitude. He explained the natural process as follows: 1. Separation of the lower pole of the ovum by retraction of the lower uterine segment during the "premonitory stage" of labor; this required a complete "bag of waters." 2. Wrinkling and partial separation of the membranes by diminution of the internal surface of the uterus; this required some escape of the waters. 3. Peeling off of the membranes by the traction of the descending placenta; this required the evacuation of the uterus. The rupture of the membranes at the proper time was an integral part of the normal process. The first stage in the process seemed calculated to prevent a very common defect,—namely, the adhesion of the membranes round the lower uterine segment.—*The British Medical Journal*, June 11, 1887.

ACETONE-CHLOROFORM—A NEW DISCOVERY.

An interesting communication (an abstract of which appears in the *Monthly Magazine of Pharmacy*) has just been laid before the Académie des Sciences by M. ENGEL, in which he describes an entirely new body lately discovered by M. Willgerodt, and designated by the not very satisfactory name of acetone-chloroform. As, from a private source, we understand that the compound in question has already been tried tentatively with regard to its effects upon the animal economy, with the result that it is said to be non-poisonous when taken internally, but lowers the animal temperature when above the normal limits, and also exerts a mild narcotic action, we trust that further researches will be instituted upon a systematic plan.

The therapeutic properties of "acetone-chloroform" should be investigated without loss of time, as, if it really possesses the properties of a sedative and an antipyretic, it can scarcely fail to become a practically valuable addition to our list of new drugs.

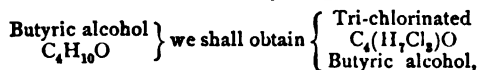

It is prepared, we are informed, by digesting, at a slightly-elevated temperature, a mixture of anhydrous chloroform and acetone in equivalent proportions, and in the presence of a little hydrate of potassium. Combination takes place without difficulty, and the principal reaction seems at first sight to be one

of simple addition in accordance with the following equation:

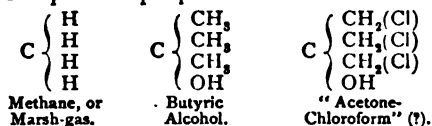

But the latter body enters into combination with the alkaline base already mentioned as being necessary to the reaction in question, forming a species of salt therewith; it thus possesses distinctly acid properties, and in fact is described as an acid by the discoverer. At the same time it must be borne in mind that as yet no reliable details of the real constitution of acetone-chloroform are forthcoming, and we must wait patiently for the further development of the interesting problem here involved. There is, however, no occasion to accept too hastily the statement that "acetone-chloroform" is really an acid at all, without some stronger evidence in support than we have before us at this moment. Alcohols are, as we all know, quite capable of forming compounds with the hydroxides of the alkali-metals, and it appears to us that this latter observation has a particular bearing upon the case.

Butyric alcohol, $\text{C}_4\text{H}_{10}\text{O}$ (like chloroform itself for that matter), for instance, belongs to that numerous class of bodies which may be classified under the "marsh-gas type," CH_4 , and of this alcohol there are or may be several isomeric modifications, as Lieben has conclusively shown. Into the details of these we cannot descend just now, but if we place in juxtaposition two formulæ of the simplest possible character, our meaning will be rendered more clear. Thus, if we replace by chlorine three atoms of hydrogen in

which, as our readers may observe, is of precisely the same composition as "acetone-chloroform."

The possible relations of the latter to marsh-gas itself may be exhibited in several ways, but a single example will be amply sufficient for our present purpose. Thus we have

So much for the hypothetical chemistry of the new compound. We may return to the consideration of the subject from a pharmacological and therapeutical stand-point upon a future occasion. It is, however, important to bear in mind that the term "acetone-chloroform" is already commercially, and quite correctly, applied to the chloroform

now manufactured upon a considerable scale in Germany (and also in the United States.—ED. W. D.) from the acetone derived from the distillation of wood and other substances. But this is merely ordinary chloroform, CHCl_3 , or, to compare it with methane,—

It therefore differs in no way from the chloroform ordinarily met with, except in the fact that it is prepared from acetone instead of alcohol.—*Western Druggist*, June, 1887.

*MANIPULATION WITHOUT INCISION AS
A POSSIBLE TREATMENT IN CER-
TAIN CASES OF STONE IN
THE KIDNEY.*

In the *Lancet* for May 21, 1887, MR. WILLIAM H. BENNETT reports the following interesting case :

An unmarried woman, 30 years old, of a spare habit and nervous disposition, came as an out-patient at St. George's Hospital in September last, complaining of symptoms which led to the suspicion that she was the subject of a calculus in the left kidney. At the same time she presented several indications of "hysteria," and stated that she occasionally suffered from fainting attacks, which were quite unconnected with the symptoms on account of which she applied for treatment. Upon examining the abdomen, which was very thin, deep pressure over the left kidney caused considerable sharp pain, and threw the superjacent muscles into rigid contraction. The kidney could be distinctly felt and moved with the hand, and seemed of the natural size and form. Taking into consideration the hysterical tendency of the patient, it could not be decided, in the absence of any very marked abnormality in the urine, with the exception of a very slight deposit of mucus and pus, whether the case was really one of renal calculus or not. Seeing, however, the ease with which the kidney could be felt, partly by reason of the thinness of the patient, Mr. Bennett determined, as drugs afforded no relief, to insure complete relaxation of the abdominal parietes by the administration of an anæsthetic, and then manipulate the kidney as freely as possible, without previously exposing it by incision, with a view, if the case were one of calculus, to disturbing the stone, and, if it were not too large, perhaps bringing about its passage down the ureter, or, in the event of the symptoms being "hysterical," with

the hope of producing a mental effect upon the patient sufficient to relieve her distress. She, however, declined the anæsthetic; the manipulation was attempted without its aid. The patient having been laid on her back upon a couch, the fingers of my left hand were dipped deeply into the abdominal wall over the kidney, the right hand being pressed forward into the loin. By a little management, the muscles being quite flaccid from the patient having become faint, the kidney could be felt quite easily between the two hands, and was kneaded as thoroughly as the circumstances allowed. The patient, although much discontented with the aching and tenderness which the operation seemed to have caused, was well enough to walk away almost directly afterwards.

Two days later she reappeared at the hospital in a more grateful mood, saying that, having suffered much discomfort for the rest of the day after the manipulation, she was seized as she was going to bed with a most acute pain in the affected loin and side of the abdomen. The pain lasted for about half an hour, during which she vomited twice. All at once an uncontrollable desire to micturate occurred, and the pain immediately ceased. No further pain followed, and there can be little doubt that a small calculus had made its way down the ureter into the bladder, although no evidence of its having passed *per urethram* was forthcoming. Moreover, it is quite possible that the manipulation had moved the stone from its resting-place in the kidney, and thus brought about its expulsion.

An isolated case like the above cannot be taken to necessarily prove much, since the passage of the calculus may have been a mere coincidence; at the same time Mr. Bennett is strongly disposed to attribute the result to the manipulation. This view receives some corroboration from a case in which the kidney was exposed and examined without the detection of a stone, although shortly afterwards an attack of renal colic was followed by the expulsion of a very small calculus, which had probably been disturbed during the exploration. Other similar cases have occurred. As bearing on the same point, it seems most probable that when relief has followed the exposure and manipulation of the kidney without the detection of a stone, the result has been due to an alteration in the position of the calculus, produced by the kneading to which the organ has been subjected. That calculi of *considerable size* may be overlooked both in the lumbar and com-

bined abdominal and lumbar operation for exposing the kidney when the organ is examined by the fingers only is certain, and it is equally certain that only stones of the smallest size can escape detection when the kidney is thoroughly explored by acupuncture,—an operation which has been at present associated with risks which are hardly more than problematic, and at all events less serious than the danger which exists of overlooking calculi of no small size when digital examination is alone employed. Manipulation of the kidney through the parietes without previous incision is possible in certain cases, the number of which is far larger than is generally supposed, when the abdominal walls are not too much loaded with fat, and the muscles have been completely relaxed by the administration of an anæsthetic. In conclusion, Mr. Bennett suggests that manipulation without incision is a proceeding worthy of trial as a treatment which may possibly prove of utility in certain cases of renal calculus, not too far advanced, as a means of changing the position of the stone and perhaps effecting its expulsion,—a possibility to our mind sufficiently strong to commend the process to the attention of physicians as an adjunct to the medical treatment of renal calculus.

BORACIC ACID IN THE TREATMENT OF LEUCORRHOEA.

From the excellent results which are yielded by boracic acid packing in chronic suppurating otitis, DR. N. F. SCHWARTZ (*St. Louis Courier of Medicine*, June, 1887) was led to employ it in a case of leucorrhœa which had resisted the most persevering use of the ordinary remedies. The experiment was successful within a fortnight, and the patient has remained well for several months since. Dr. Schwartz states that he has been equally successful in a number of other cases. His manner of using it is as follows: Having first irrigated the vagina with water at as high a temperature as can well be borne by patient, a cylindrical speculum is introduced, and the vaginal walls very carefully dried, first with a soft sponge and then with absorbent cotton. This done, boracic acid in crystals is poured into the mouth of the speculum, and pushed up against the uterus and vault of the vagina with a clean cork caught in a uterine sponge-carrier, sufficient acid being used to surround and bury the intravaginal portion of cervix, filling the upper part of vagina. A tampon of absorbent cotton is then firmly pressed against

the packing, and held *in situ* until the folds of the vaginal walls close over it as the speculum is withdrawn.

This should be allowed to remain three or four days, or even longer, as after this time there still remain some undissolved particles of the acid, nor will the tampon seem at all offensive. The ostium vaginae, if examined in twenty-four hours, instead of being besmeared with the leucorrhœal secretion or discharge, presents a clean appearance, and bathed in a watery fluid, which begins to appear several hours after the packing has been placed, and in his cases this was the only discharge noticed afterwards.

However, a second or even a third repetition may be necessary, but in none of his cases, numbering nearly a score, has he found more than a second packing called for, and in many one sufficed; and in no instance has its use occasioned pain, not even inconvenience.

THE STRING-DRAIN AS A SUPPLEMENT TO THE ORDINARY DRAINAGE-TUBE.

DR. A. R. JENKINS proposes in the *Annals of Surgery* for May, 1887, as an adjunct to the drainage-tube, the introduction of one end of thirty or forty feet of rough string, highly hygroscopic, and completely aseptic, through the usual "Chassaignac drainage-tube," so that, when the last is placed in the wound, the string may be drawn through, from time to time, as will be explained hereafter.

The string may be of cotton, linen, or wool, that has been freed of fat and disinfected, for which purpose it is recommended that it be treated after the manner that V. Bergmann prepares his gauze,—by immersing the absorptive string for one hour in the following: Sublimate 1, glycerin 50, alcohol 100, water 150, warmed; then to be dried, and kept in hermetically-sealed glass jars; it will then hold one-third per cent. sublimate, and is very absorbent. The end of the string being passed into the tube, and the tube placed in the wound, and it closed, then the strings and aperture or apertures of the tube are covered by the usual protective of "gutta-percha paper" or "Lister's oiled silk," to hinder evaporation or gluing of the string. The string is now tried to see that it draws freely, and is so placed that it lies along the line of least resistance, and closely applies to the body's surface; over the gutta-percha paper and string the gauze and cotton,

etc., are to be placed. The coil of the string may be kept in an antiseptic magazine, such as a glass bottle, which can be included in the bandage or left out, as desired; in the last case, when not being used, the bottle should be tightly stoppered, and covered by an antiseptic bandage. The draw-end should be left out, and can be drawn upon from time to time, as may be necessary, until it comes free of secretion.

The soiled end of the string can then be cut away, and it and the bandage at its emergence disinfected with a saturated solution of iodoform in ether.

The other end should be protected most rigidly against infection, as mentioned above.

Or the string might be placed in a coil in the wound itself, in form of tampon, and passed out through a drainage-tube.

This might apply in wounds such as would be left after the removal of tumors (as lipoma), or might thus be used with Martin's drainage-tube in "Douglas's fossa."

The process advocated is recommended during the first forty-eight hours, when the wound is pouring out a large quantity of serum, before granulation is established on the wound's walls, which follows especially operations in which "carbolic" or other irritants are extensively employed, and in this time the tube is most likely to be stopped by coagula.

A SPEEDY AND SOMETIMES SUCCESSFUL METHOD OF TREATING HAY FEVER.

SIR ANDREW CLARK, in an address delivered before the West London Medico-Chirurgical Society, describes as follows a method of procedure which he has employed with considerable success in the treatment of hay fever. For this treatment there are required a common laryngeal brush and a carbolic mixture, the latter being composed of glycerin of carbolic acid, one ounce; hydrochlorate of quinine, one drachm, and one-thousandth part of perchloride of mercury, heat being required to dissolve the quinine. If there is much mucus in the nostrils, cleanse them by means of a douche of warm water containing boroglyceride, in the proportion of an ounce to the pint. Dip the laryngeal brush in the carbolic acid mixture, and see that the brush is full but not overflowing. Place the left hand on the left side of the forehead, and the thumb on the tip of the nose, with the shank of the brush between the thumb and two forefingers of the right hand, and the brush itself directed upwards, push it gently but firmly into one of the nos-

trils, carry it as high as you can without inflicting injury, move it about so as to bring the mixture in contact with as much as possible of the interior of the upper part of the nostril, and then withdraw it. With another brush filled with the carbolic acid mixture, or with the same brush washed, dried, and replenished, you complete in the manner following the two operations required for each nostril. Having the left hand in the position already described, and the right hand holding the laryngeal brush, with the hair pencil directed forward from the body of the operator, push the brush along the floor of the nostril into the pharynx, and after insuring free contact with the adjacent parts, withdraw it. If during the operation the brush is overfull, some of the carbolic mixture will fall into the throat and excite coughing or some other discomfort. When you have thus finished the treatment of one nostril, and carefully removed any of the carbolic acid mixture which may have been spilt upon the nose or lips, you will proceed to treat the second nostril in exactly the same manner as you have dealt with the first. During the performance of these manœuvres great assistance will be obtained from the left hand of the operator being placed over the left side of the forehead and face of the patient. With this hand the operator can adjust the patient's head to the various movements of the laryngeal brush, and with the same hand placed on the tip of the patient's nose the opening of the patient's nostril can be adjusted to a convenient size and shape. When the local effects of a paroxysm are severe, and have extended to the back part of the soft palate, it will be desirable to introduce through the mouth into the pharynx the laryngeal brush moderately filled with the carbolic acid mixture, and there, by a manœuvre easily acquired and practised, to brush the posterior surface of the soft palate and the adjacent parts. The immediate effects of these manœuvres differ in different persons, and in the same person at different times. In all cases the effects are more or less disagreeable, and last from half an hour to half a day. Sometimes a little blood-stained mucus is discharged from the nose and throat; sometimes there is a slight frontal headache; sometimes there is a trivial cough, and occasionally you will have developed all the local phenomena of a paroxysm of hay fever.

When advising a patient with hay fever to submit to this plan of treatment for its relief, it is expedient to warn him beforehand of

the disagreeable effects which sometimes follow the application of the carbolic mixture, and to assure him that they are both brief in duration and devoid of danger. When this warning is withheld, some patients will grossly exaggerate their sufferings, ascribe all sorts of injurious consequences to the application, and cover the physician with undeserved reproaches. Sometimes a single application of the carbolic acid mixture is sufficient to prevent for a whole season the return of the hay fever paroxysm, and four times within the writer's own knowledge it has never reappeared. Usually two or three applications are necessary to insure a full chance of success. The length of the interval between the applications must be determined by the character of the immediate effects. If these are mild, the application may be renewed on alternate days; but if severe, at least three days should elapse between succeeding applications.—*The Lancet*, June 11, 1887.

SALOL.

As an extension of what we have already published on this subject, we abstract the experience and formulæ of GEORGI, of Görlitz, and SAHLI, of Berlin, regarding this remedy, which, although used in foreign practice, has not been thoroughly tested by the profession of America.

In rheumatism the unpleasant after-effects observed by other investigators were not observed. The carbolic-acid coloring of the urine persisted during the entire time of administration.

Average dosage per diem was from 3iiss to 3iii. In general the drug possessed little advantage over salicylic acid.

The antipyretic dose was 15 grains to 30 grains. A mouth-wash and gargle composed of 3ii to 3iiss of a four or five per cent. alcoholic solution, added to 3vi $\frac{1}{2}$ of water, was found useful.

The following are different formulæ for salol:

R Salol, gr. xv;
Ol. menth. pip., q. s. ad odorem. M.
Ft. chart. 10 in num.

One powder to be placed on the tongue, and swallowed with water.

Compressed tablets having been found unreliable, the following combination with starch is useful:

R Salol, gr. viii;
Amyli, gr. iss.

To be made into 10 tablets.

For external use in ulcers and skin-diseases:

R Salol, gr. vi to 3i;
Ol. olivarium,
Adipis,
Lanolini, aa 3x.

In using salol as a powder it should be combined with starch, as

R Salol, gr. viii to lxxx;
Amyli, 3xiiss.

A mouth-wash of salol is prepared according to the following:

R Ol. menth. piper., m lxxv;
Caryophyllor.,
Cort. cinnam. Zeyl.,
Fruct. anisi, aa 3iiss;
Spiritus, Oii;
Cocconelli pulver., gr. lxxv.

Digest for eight days, and to the filtered fluid add Salol, gr. xl.

This liquid should be added, drop by drop, to one-fourth glass of water, until a milky cloudiness results.—*Therapeutische Monatshefte*, Heft 4.

THE REPARATIVE TREATMENT OF SOME OF THE GRAVER FORMS OF VESICO-VAGINAL AND VESICO- UTERINE FISTULÆ.

At a recent meeting of the Academy of Medicine in Ireland, held April 1, 1887, DR. MORE MADDEN read a paper on the treatment of certain forms of vesico-vaginal fistulæ. Notwithstanding the great advance of modern gynæcology, in no respect better known than in the operative procedures by which vaginal fistulæ have been so generally rendered amenable to ordinary reparative treatment, the management of some cases of this kind still presents one of the most difficult problems that occasionally occur in our special line of practice. In the present communication the writer confines himself to those more difficult and exceptional cases of vesical fistula consequent on parturition. Among these Dr. More Madden includes all cases of vesico-uterine fistula in which the loss of tissue or the position and character of the rupture are such as to preclude the restoration of the former structural integrity of the parts, and in which either new vesico-vaginal or vesico-uterine walls must be built up by plastic operation, or else a new condition of the parts must be established. In most of the instances of vesico-uterine fistula that have come under Dr. More Madden's observation the patients

had been delivered instrumentally; and, moreover, were pluripara in whom the uterine walls had been previously softened and disintegrated by imperfect involution. In the latter cases there are, as a rule, but three courses available in the way of operative treatment,—viz., tracheorrhaphy in the first instance, followed by a plastic operation on the disrupted vesico-uterine walls; secondly, closure of the os uteri, so as to convert the uterus into an appendix to the bladder; or, thirdly, the same result may be obtained in some cases by turning the cervix into the vesical wound, within the closed walls of which it may be included. In this connection Dr. More Madden refers to a case in which, after the normal aperture of the uterus was thus closed, nevertheless the patient subsequently again became pregnant. In some exceptional instances, however, of destruction from sloughing of the entire vesico-vaginal septum, none of the reparative operations usually recommended are feasible or effectual, and in such cases the advisability of closing the vaginal orifice, so as to thus afford a possible restitution of retentive power, becomes a question for consideration. Against Simon's operation for this purpose must be recognized the consequent liability to fatal renal disease, which Dr. Emmet holds to be an inevitable result of its performance. Nor should it be lost sight of in this connection that in some instances the most extensive vesico-vaginal fistulæ may in course of time become cured without any operation by the occurrence of senile atresia of the vagina,—a fact of which two cases have come under Dr. More Madden's observation. Such instances are, however, far too exceptional to have any practical influence on the determination of the line of treatment to be adopted in any case of this kind; and in some instances, fortunately exceptional, there is no alternative to abandoning a sufferer from vesico-vaginal fistula to a life of hopeless misery, or else resort to closure of the vaginal orifice. A somewhat remarkable case of this kind is detailed in which the writer succeeded in thus curing a very extensive fistula by a modification of Simon's operation. Dr. More Madden adds that whilst regarding his modification of Simon's operation for closure of the vagina merely as a *dernier ressort*, to be adopted only in some exceptional instances of vesico-vaginal fistula otherwise incurable, this procedure, nevertheless, appears to him to be deserving of consideration in such cases. Therefore, although yielding to no one in his respect for Dr. Emmet's authority, he

would not, even by that condemnation, be deterred from again resorting in any similar case to the operation by which the patient referred to was benefited. Whether in this case any renal disease supervened or not there was no data to say. Dr. More Madden, in conclusion, observed that a patient whose condition had for years previously been as miserable as any that could well befall a woman, and who, to the best of his judgment, was otherwise incurable, was, by the operation referred to, restored to a state of comfort and apparent health, which continued for eighteen months subsequently, when her death from fever occurred.—*Medical Press*, June 8, 1887.

*CURE OF A CANCROID OF THE LARYNX
BY EXTIRPATION THROUGH THE
NATURAL PASSAGES.*

FRÄNKEL, of Berlin, reports a case in which a tumor, the size of a bean, was situated on the right vocal cord, which he removed by a snare four times in succession, and which each time returned promptly. He made a diagnosis by the microscope of a cancrroid growth, and in June, 1884, he again removed it in two sittings by means of the snare. Although he omitted to cauterize the site of the tumor with the galvano-cautery, as he had previously done, the growth did not return, and the patient, although 75 years old, has since remained well. He has also, oddly enough, preserved his voice, and can be truly regarded as recovered. Fränkel thinks that this case shows the superiority of intra-laryngeal operations for cancrroid, and he advises the following rules for operation: In all cases where the site of the tumor is definitely ascertained, as large a portion as possible should be removed with the snare or forceps, through the larynx, and under the influence of cocaine. If the microscopic examination shows a cancer to be present, and no especial danger that the cancer implicates both sides exists, an effort should be made, under anæsthesia, if needed, to remove the growth from its position with the forceps or snare. The patient should be kept under observation with the laryngoscope, and each returning mass removed in the same way. If a complete removal cannot be effected by intra-laryngeal operation, partial resection should be performed. If both sides of the larynx be implicated, the question may yet be raised whether a removal by intra-laryngeal procedure is not feasible.—*Centralblatt für die gesammte Therapie*, June, 1887.

RAPIDITY OF THE BLOOD-CURRENT IN THE KIDNEY AND OTHER ORGANS.

According to the Vienna correspondent of the *British Medical Journal*, June 4, 1887, DR. GÄRTNER, assistant to Dr. Stricker, Professor of General and Experimental Pathology, recently made an interesting communication to the Imperial-Royal Society of Physicians of that city on the rate at which the blood flows in the kidney and other organs. Several similar experiments had previously been recorded. Claude Bernard examined the rapidity of the blood-current in salivary glands when at rest, and when subjected to irritation; Sadler and Gaskell (under the direction of Ludwig) that in passive and in irritated muscles; and among the researches on this subject made in the Ludwig laboratory, must also be mentioned those of Slavjanski on the rapidity of the blood-current in the inferior vena cava, and of Basch and Tappeiner on its rate of movement in the portal vein. This method of separately examining each organ as to the rapidity with which the blood passes through it has, however, other advantages besides the immediate results obtained by these inquirers. Each organ can thereby be examined as to the presence of nerves in the blood-vessels, and as to the different conditions under which these nerves act either in the way of narrowing or distending the vessels. Some hints for therapeutic use might also be got by ascertaining the various ways in which the vessels of a particular organ are influenced in respect of the quantity of blood contained in them. This mode of investigation, moreover, makes it possible to perform comparative experiments as to the quantity of blood passing through two different organs of the same animal in equal spaces of time. From such experiments it is clear that the rapidity of the outflow of the blood from the renal vein is greater than that from the femoral vein below Poupart's ligament, though the region drained by the latter is comparatively much larger. Dr. Gärtner performed his first experiments on the kidney of the dog. A canula, provided with a tube to carry away the outflowing blood, was introduced into the renal vein, and the blood-current was observed either by counting the blood-drops as they fell, or by Ludwig's graphic method. When the operation was performed with sufficient care, and without doing any injury to the kidney itself, the loss of blood was comparatively slight, and did not interfere in any way with the experiment. In a curarized animal, when artificial respira-

tion was suspended, the rapidity of the blood-current diminished exactly in proportion as the blood-pressure increased. In three cases, not a single drop of blood escaped for more than a minute, when the animal was near suffocation. The oscillations of the blood-pressure were also shown by the quantity of outflowing blood; to each fall of the blood-pressure curve corresponded a quicker dropping of blood, and when the arterial blood-pressure increased the drops again fell more slowly. It was known that when the suffocation of the animal was continued for a longer time, the blood-pressure again decreased, but there was no corresponding increase in the number of falling blood-drops. This was another proof of the truth of the theory established by T. Wagner and Openchowski, that the decrease of the blood-pressure which preceded the death of the animal did not arise from weakness in the blood-vessels, but from diminished action of the heart. Dr. Gärtner further remarked that Carl Ludwig and Thiry had, by direct inspection of the exposed kidney, observed that it became pale, and that the blood-vessels contracted when the medulla oblongata was irritated. This phenomenon, on which one of the most important points of the doctrine of circulation is based, when produced in the manner described by Carl Ludwig and Thiry, is so slight that no exact idea can be obtained of it, even when the experiment is repeated for several times. By the experiment of the outflow of the blood, however, the contraction of the vessels can be demonstrated even to a great audience. Besides the kidney, Dr. Gärtner said he had performed some experiments on the crural vein. On suffocation of the animal, the action of the blood-current was contrary to that in the renal vein. The blood-drops fell with a rapidity directly proportional to the increase of blood-pressure. Such an antagonism had already been proved to exist by other methods; for instance, it had long been known by thermometry that after division of the sciatic nerve in animals the blood-vessels of the hind legs became paralyzed. It was observed that, in such cases, the temperature of the hind legs was raised, and their size also increased, as well as the pressure in the veins. Here also no other mode of operation could produce the phenomena in so striking a manner as what may be called the bleeding method. Before the sciatic nerve was cut through, the blood could be seen falling drop by drop from the mouth of the canula, while after division of the nerve-trunk it gushed out with

great force and rapidity, as if a sluice had been opened. Its flow could again be diminished and slackened when the peripheral end of the sciatic nerve was irritated by electricity. Dr. Gärtner stated that, together with Dr. T. Wagner, he had performed similar experiments on the brain, and that he would give an account of them at one of the next meetings of the society.

CASEIN AS AN EMULSIFIER.

At the last meeting of the Paris Pharmaceutical Society, M. LÉGER submitted some information respecting the employment of casein as an emulsifying agent (*L'Union Pharm.*, May 16, p. 193). Considering that the natural emulsions, such as vegetable juices, milk, etc., owe their peculiar condition to the influence of albuminoid substances, he inferred that these substances might be utilized in preparing artificial emulsions if they could be separated in a form convenient for manipulation and preservation. Casein, which so perfectly emulsifies butter in milk, was chosen for the experiment. It was separated by adding sixty grammes of ammonia to four litres of milk, and after twenty-four hours' contact removing the soapy layer that collected at the top, and then precipitating the serum with acetic acid. The magma of casein, after being strongly pressed, was mixed with ten grammes of sodium bicarbonate and sufficient sugar that the product should contain ten per cent. of its weight of casein: This "saccharide of casein," when powdered, is said to be easily soluble in water, and capable of being employed in the same proportion as gum in making an emulsion, without requiring the use of a mortar. The sole defect admitted by M. Léger is that the "saccharide" gives off a slight animal odor.—*The Pharmaceutical Journal and Transactions*, May 28, 1887.

WILL THE KNEE-JERK DIVIDE TYPHOID FEVER FROM MENINGITIS?

Dr. Hughlings Jackson asserted recently at the Medical Society of London that loss of knee-jerk might prove of service in the diagnosis of meningitis from typhoid fever; for he had never known knee-jerk to be absent in typhoid fever, whilst he had found it to be wanting in cases where the necropsy ultimately proved the disease to be meningitis.

At the same meeting Sir Dyce Duckworth asserted that the knee-jerk might be absent in undoubted typhoid fever. Further light is

thrown upon this subject by a paper by DR. ANGEL MONEY, in the *Lancet* for May 21, 1887. He suggests that prolonged pyrexia with all that it involves, whether in the way of direct deterioration of protoplasm by the fever heat or of indirect deterioration by collateral consequences of the pyrexia, is the cause of the very general exaggeration of the deep reflex and muscular irritability to be found in typhoid fever, phthisis, and other continued fevers, and he states that he has not seen a case of typhoid fever in which the knee-jerk was lost; though the jerk may have been absent on the day or so preceding death in fatal cases, which are rare at the age at which tubercular meningitis is common. On the other hand, tubercular meningitis does not always cause the disappearance of the knee-jerk. Sometimes the knee-jerk is increased in cases of undoubted tubercular meningitis, but only when the child is unconscious or nearly so. He has even observed, in company with Dr. Gee, that tapping of the patella tendon on one side caused powerful contraction not only of the quadriceps extensor of the same side, but also of the adductors of the thigh of the opposite side, in a case of tubercular meningitis. Such phenomena will not be found to be very uncommon if they be diligently searched for, and may be seen in diphtheritic paralysis, as well as in tubercular meningitis and phthisis. In order to answer so far as is possible the question which forms the title of this brief communication, Dr. Money formulates the following propositions: Given a case of fever with morbid mental phenomena, without a typical rash, optic neuritis, or choroidal tubercle, or any sign of cranial nerve paralysis or irritation, if the knee-jerk is lost on both sides during the illness, and the wasting of muscle is unattended with loss of response to the faradic current, the diagnosis should be meningitis rather than typhoid fever. If the knee-jerk be exaggerated, and if there be ankle-clonus, no certain conclusion can be drawn, for these conditions occur both in typhoid fever and in meningitis (and other conditions). That increase of the jerks (with or without ankle-clonus), accompanied by lively spontaneous flickerings (fibrillar contractions) of the muscles, is much more likely to be due to prolonged pyrexia than to direct disturbance of the nervous functions from meningitis or other nervous irritation. If typhoid fever be complicated with myelitis or meningitis—complications of rare occurrence—then the jerk may be lost, whilst in tubercular

meningitis its disappearance for a few hours, or a day, or a few days, is by no means rare. A variable state of the knee-jerk—*e.g.*, one day present, next day absent, and a third increased—points to meningitis, not fever.

To make what may be considered a curious comparison, Dr. Money thinks that the differential diagnosis of meningitis from mere fevers might be assisted far more by the state of the knee-jerk than by the swelling of the spleen; for unless the splenic enlargement be enormous, tubercle as well as typhoid fever and other diseases—*e.g.*, pyæmia—will account for the splenic swelling; whereas absence of the knee-jerk, or rather ascertained disappearance of the same, is practically never met with as the simple outcome of prolonged pyrexia.

A NEW OPERATION FOR HEPATIC ABSCESS.

DR. GEORGE ZANCAROL, of Paris, describes the following operation as performed by him for hepatic abscess.

The operation consists in making a large opening sufficient to expose the whole cavity of the abscess, and in thoroughly cleansing it of all pus and *débris* of sloughing hepatic tissue. It may be divided into three stages: 1, exploration of the liver; 2, opening the abscess; 3, cleansing the abscess-cavity.

1. *Exploration of the Liver.*—After having well washed the skin with a brush and soap and water, and a two per cent. solution of carbolic acid, an exploring trocar is plunged into the liver to find the abscess; this exploratory puncture may have to be repeated several times, so that a good idea may be formed of the size and direction of the abscess.

2. *Opening the Abscess.*—An opening is made with the thermo-cautery into the lower third of the abscess, five to seven centimetres (two to nearly three inches) long, according to the size of the abscess, and as much as possible in the direction of its greatest diameter. This opening must be sufficiently large to enable the surgeon to see the whole cavity with ease when the edges of the opening are held well apart by retractors. To obtain this result in abscesses of the left lobe an opening in the soft parts will suffice; but if the abscess is in the right lobe, resection of one or two ribs will be necessary. This resection is also performed with the thermo-cautery, using an elevator to detach the periosteum, and Liston's bone-forceps, care being taken not to wound the intercostal artery; should this, however, happen, the hemorrhage will cease

as soon as the abscess is opened. After resection of the bone, the abscess is opened with the thermo-cautery, keeping always in the direction of the resected rib, and with the aid of two strong retractors held by an assistant, while the margins of the incision are kept open, they are pressed against the liver, and kept in close contact with the abdominal and thoracic walls, so as to prevent either pus, or the liquids used for washing out the abscess, from finding their way into the abdominal or pleural cavities. If this precaution be observed no harm will result, even should there be no adhesion between the wall of the abscess and the parietal peritoneum; for when once the abscess has been thoroughly washed and cleansed, adhesions will be established before fresh pus can accumulate. In fifty such operations performed by the writer during the last two years, it is stated that no purulent matter has ever escaped into the pleural or peritoneal cavities, although cases were operated upon in which no adhesions existed.

3. *Cleansing the Abscess-Cavity.*—The retractors being still held in the position already described by an assistant, a strong current of warm distilled water is allowed to play within the abscess-cavity by means of a siphon; every particle of adherent pus and necrosed tissue is removed with the fingers, or with sponges fitted to proper holders, and the washing out is continued until the walls of the cavity look perfectly clean, often granulating, and the water returns clear. The retractors are then withdrawn, two drainage-tubes of large calibre are inserted in the cavity, and the dressings applied, which are left undisturbed for twenty-four hours; the cavity is then washed out again with warm distilled water, as above described, and the current kept on until the water returns perfectly clear.

As a rule, the temperature becomes normal immediately after the first washing, but if fever should reappear, or if the pus is abundant, the washing-out should be repeated every twelve hours; if in spite of all this the fever persists, or diarrhoea sets in, this would indicate that other abscesses exist in the liver, and such cases are invariably fatal.—*British Medical Journal*, June 11, 1887.

THE TREATMENT OF TYPHOID FEVER BY ANTIPYRIN AND THALLIN.

At a recent meeting of the Association of American Physicians, Dr. FRANCIS MINOT, of Boston, read a paper on the above subject,

in which the following conclusions were reached: 1. Both antipyrin and thallin have a remarkable power of reducing the temperature in typhoid fever. 2. In no case was the use of these refrigerants apparently followed by any unfavorable effect upon the course of the disease. 3. The general condition of the patient was more comfortable after taking antipyrin and thallin, which were often followed by sleep. 4. The refrigerant medication by antipyrin and thallin appears to have no specific or decided effect upon the course or issue of typhoid fever. It often contributes much to the patient's comfort; perhaps indirectly promotes his safety. 5. The effect of antipyrin and thallin in promptly lowering the temperature shows that the danger in typhoid fever does not consist in high temperature alone, and that the latter is rather an index of the violence of the abnormal condition which we call fever, though perhaps adding somewhat to the danger. 6. By the internal use of antipyrin and thallin all the effects which are claimed for the treatment of typhoid fever by the cold bath are readily obtained without the trouble and inconvenience of the latter method, and without exposing the patient to the dangers of exhaustion and shock consequent on the fatigue of removal from bed. 7. These remedies may be given without danger to the youngest patients in suitable doses, and, indeed, their beneficial effects are more decided and the unfavorable consequences are less observable than with adults. —*Medical Record*, June 11, 1887.

THE TREATMENT OF THE DYSPEPSIAS OF INFANCY, AND THEIR CAUSATION BY MICROBES.

HAYEM, of the Hospital of Saint Antoine of Paris, reports the following interesting observations in a pavilion in the hospital especially devoted to very young children:

"Shortly after going on duty at the hospital my attention was attracted by the frequency and gravity of the gastro-intestinal disorders of the children under my charge. These cases are, as is well known, among the most common of diseases among such patients. At the beginning I tried to combat them with the ordinary means of treatment at present recognized: regulation of the times of nursing and of all artificial foods, the use of alkalies, absorbent powders, calomel, hydrochloric acid, and, when vomiting was present, cocaine or sedative compounds. Hydrochloric acid had formerly seemed to me

to give the best results. But such results were irregular, at times excellent and well sustained, afterwards transient and incomplete, and more often nothing at all. After finding the matter ejected from the body is generally, in such cases, neutral or feebly alkaline, the idea suggested itself of trying another acid, and I was pleased to find in lactic acid a remarkably useful medicament.

"Meanwhile some of the children, apparently cured by lactic acid, were taken with relapses after the medicine was stopped. With others the acid seemed to lose its effect. It was also noticed that as soon as several patients, suffering from diarrhoea with greenish stools, were brought into the wards an epidemic of this disease appeared and became quite general. The contagiousness of the disease impelled me to order that all linen soiled with dejecta or vomit be soaked in a solution of bichloride of mercury, 1 to 1000. Upon this the diarrhoea ceased. The lactic acid was given in a solution of 2 to 100, in teaspoonful doses, a quarter of an hour after nursing. From 5 to 8 teaspoonfuls may be taken in twenty-four hours, amounting to from 6 to 9 minims of pure lactic acid. The effects of this treatment were promptly recognized. When vomiting was present it immediately ceased, the number of stools decreased, and the dejecta lost their characteristic green color and became yellowish. As soon as the stools became normal, in regard to color and consistence, and in two or three days (rarely in five or six), the patient was cured. But this result was only obtained when the prophylactic measures described were fully carried out. Several times neglect of these measures caused the disease to reappear, when strict observance caused it again to disappear.

"In the course of four months all the children had rapidly recovered, and the epidemic had not spread to their neighbors. In cases of tuberculosis and children in the last stages of collapse, the dyspepsia and diarrhoea were not completely suppressed by lactic acid. But even in these cases the character and color of the stools were changed, and they became yellow. While I had been occupied with the treatment of these cases, the resident physician, M. Lesage, began experiments to seek the cause of the coloring of the stools. It was not long before he was able to recognize in the greenish dejecta a particular bacillus which formed in considerable masses. He was able to isolate and cultivate this microbe, which produced the green matter by a sort of excretion, and it was owing to his studies

that these interesting results were obtained. Among other valuable facts demonstrated he showed that lactic acid, whose curative power in the children we had learned, had the property of destroying, even in dilute form, cultures of these bacilli made upon peptonized gelatin. These experiments seemed to me to explain satisfactorily the contagion of the disease. Still, they could not entirely prove that the disease had been caused by the introduction from without of the bacilli into the digestive tract. It was true, from conditions always present in the diarrhœas of children, that the microbe of diarrhœa with green stools could find, by reason of a previous modification in the character of the secretion of the digestive tract, a nidus favorable to its development and multiplication. This probably happens as follows: The microbe gains entrance to the stomach with food, and under ordinary conditions finds a medium favorable to its multiplication. In dyspepsia the secretions of the stomach are altered, and the microbe comes into the intestine without having lost its vegetative power. There it finds a medium of neutral or alkaline reaction which permits it to multiply with great activity, and produce the green color of the stools of diarrhœa. Lactic acid can act in two ways,—by combating the dyspeptic condition and rendering the contents of the stomach properly acid, or by sterilizing the germs of the bacilli, as we observed that it was sufficient, when experimenting upon cultures, to add a small amount of lactic acid to cause the spores of the bacilli to die.

"M. Lesage has undertaken experiments which will endeavor to produce diarrhœa with greenish stools in young animals by pure cultures of this bacillus, to determine precisely the conditions favorable for producing the germination of the bacilli in the digestive tract. His results are needed to explain the action of lactic acid. Meanwhile, the use of analogous agents was indicated. I have already spoken of the efficacy, in some degree, of hydrochloric acid in such cases. It is an antidyseptic agent whose action is as difficult to explain as is that of lactic acid. I can only remark that all acids certainly hinder, outside the organism, the development of bacilli; but under the conditions obtaining when they are given in illness, they acidulate only the contents of the stomach. If we can demonstrate that they act as germicides, it must be admitted that they sterilize in the stomach the germs which would otherwise develop in the succeeding portions of the digestive tract. In

addition to the acids we have the great number of disinfectants proper, among them naphthalin, iodoform, sulphide of mercury, and calomel has seemed to me to merit trial in this category. This drug has been elsewhere recommended as one of the best for this purpose. After having made trials with these substances, lactic acid has seemed to me preferable. It is perfectly well borne, it is easily and simply given, and its results have been to me very conclusive. In conclusion, the stools of nursing children suffering from diarrhœa owe their color to a material produced by a specific bacillus. It is probably produced by a dyspeptic condition which permits the bacillus to find in the digestive tube a medium suitable for its growth. I believe, further, that I am justified in saying that this diarrhœa is contagious, and that germs deposited upon linen soiled by dejecta are the agents of the contamination. However this may be, before the questions raised by the demonstration of the microbic origin of diarrhœa with greenish stools are definitely settled, I do not wish to delay longer in bringing to the notice of the profession the prophylactic and curative treatment which has made me, in a sense, master of this formidable malady, with the hope that my colleagues will come to confirm the value of this treatment."—*Bulletin Général de Thérapeutique*, May 30, 1887.

THE TREATMENT OF LUPUS BY SCRAPING.

At a meeting of the Liverpool Medical Institution MR. RUSHTON PARKER read a paper on the treatment of lupus by scraping, which in some form he recommends and performs in lupus of all kinds and stages. In the most extensive degrees of lupus ulcers he uses Volkmann's sharp spoon, in the slighter forms of pustular, scabby, or erythematous lupus, especially when also recurring on a small scale after partial healing of serpiginous cases, he uses a blunted gum lancet, a blunted wide-eye spud, the point of a tooth-elevator or tooth-scaling instrument, according to the size of the nodule to be scraped away. The part is rendered bloodless by ring-compression with the aid of stout wires of various sizes mounted in handles, and ending obliquely in a ring which is pressed into the skin around the spot to be scraped, facilitating the recognition and removal of every particle of lupoid tissue. Before removing the ring, nitrate of silver is rubbed into the raw surface, preventing or arresting subse-

quent bleeding, and providing a dry aseptic scab for the next two or three days. Two cases were shown that had been for fifteen years under treatment,—one a typical case of extensive ulcerating lupus of the face, including cheeks, nostrils, nose, lips, gums, and even the inside of the upper eyelid; the other, a marked case of erythematous lupus of cheeks and nose. The former had almost recovered after two or three scrapings during the last twelve months, the latter after seventeen scrapings (on a very small scale at each spot) during the last two years at intervals of from twelve days to three months. What is claimed by scraping is thorough and accurate removal of morbid tissue, without waste or injury to the neighboring healthy parts it otherwise keeps unhealed.—*Medical Press*, June 8, 1887.

THE ACTION OF HYDROCHLORATE OF HYOSCINE.

Under the direction of Kobert, SOHRT, according to the analysis of his paper published in the *Medical Chronicle* for June, 1887, by Dr. D. J. Leech, has made a series of experiments on the physiological action and therapeutic use of hyoscine, the results of which are published in the above paper. The conclusions arrived at by Wood, as to the manner in which hyoscine influences the various organs, are to a large extent confirmed, but on some points the views of the American and German observers are not in accord.

In healthy men the injection of $\frac{1}{10}$ of a grain gave rise, according to the latter, to disturbances of co-ordination and some muscular weakness; the head felt heavy, sank on the shoulder, and could only be lifted up with difficulty; the limbs likewise felt heavy, and the upper eyelid could hardly be raised; there was a sense of fulness of the head, the pupils were dilated, and a tendency to sleep was noticed in every case; the throat was dry. The hallucinations, delirium, nausea, and trembling, which have been described by Wood and other observers as following the administration of the hydrobromate and hydroiodate of hyoscine, were not observed by Sohrt and Kobert.

Hyoscine, according to Kobert, even in large doses, is well borne by some of the lower animals; a cat recovered after 9 grains, and a small rabbit was unaffected by 3 grains. After large doses it is excreted unchanged by the kidneys. It influences but little the cerebral functions of the lower animals, but has

a markedly calming effect on man when the brain is excited. The depression of the reflex excitability of the spinal cord, which, according to Wood, was present in lower animals after the administration of hydrobromate, was not observed in the experiments made by Sohrt.

Claussen, who published his investigations on the action of hyoscine in 1883, stated that this drug stimulates the vagus and decreases the heart's frequency. Wood concluded that it had no influence on the vagus. Kobert, however, is of opinion that it paralyzes the vagus terminations in the lower animals, and probably also in man. In a lunatic with depressed circulation, which he attributed to inhibition exerted by the brain on the heart, he found that hyoscine always improved the pulse. In healthy men, however, increased rapidity of the pulse, which ought to follow vagus paralysis, was not always noticed. It antagonizes the influence of muscarine on the heart. In cold- and warm-blooded animals it dilates the peripheral vessels, probably by its paralyzing influence on the ganglia contained in their walls. Kobert does not think that it influences the vaso motor centre, as the experiments of Wood led him to believe. The respiration is unaffected, according to Kobert, while Wood considers that this drug has a depressing influence on the respiratory functions, acting in all probability on the respiratory centre.

Hyoscine certainly diminishes the secretion of saliva, hence the drying of the throat which follows its use. The secretion of perspiration, too, is lessened, and some of Sohrt's patients, who tried both hyoscine and atropine to check sweating, preferred the former drug.

It is well known that muscarine increases intestinal peristalsis; hyoscine antagonizes this influence, paralyzing therefore the nerve apparatus on which muscarine acts.

According to Dr. Emmert, of Berne, hyoscine acts more energetically and rapidly as a mydriatic than either atropine or duboisine, and is effective even in solution of 1 part to 1000. Kobert, however, states that complete dilatation of the pupil is only produced by full doses. It acts, he says, by paralyzing the periphery of the oculo motor nerve. Sohrt found that $\frac{1}{10}$ of a grain dilated his pupils without paralyzing accommodation. Sohrt gave subcutaneously from $\frac{1}{10}$ to $\frac{1}{100}$ of a grain to a number of lunatics suffering from mental excitement and insomnia, who had taken other calminatives in vain. He administered the drug about one hundred times.

Sleep was always produced, and no threatening symptoms were noticed.

As a rule, the patients fell asleep in ten to fifteen minutes after the injections, and did not awake for five to eight hours. A little fullness of the head was at times complained of during the morning following an injection. It is specially worthy of remark that the hyoscine produced good results in several cases in which hyoscyamine in full doses had been ineffectual. Kobert is inclined to consider hyoscine beneficial as a sedative in mental diseases only.

EXTIRPATION OF THE CRICOID CARTILAGE FOR ENCHONDROMA.

Böcker, of Berlin, reports in the *Centralblatt für die gesammte Therapie*, June, 1887, the case of a man, aged 62, on the cricoid cartilage of whose larynx there was a hard tumor as large as a hazel-nut. After performing tracheotomy, examination with the finger showed that the tumor was not movable, but embodied with the flat and also curved surfaces of the cricoid cartilage. The operator then introduced a tampon canula, and split the larynx to the hyoid bone, sawing through the thyroid cartilage, and extirpated the cricoid cartilage, leaving the arytenoid cartilages behind. The tumor proved to be an enchondroma, with the formation of spongy bone-substance in its interior. The patient recovered from the operation, but was obliged to wear a permanent canula, as the vocal cords approximated otherwise on inspiration. Deglutition was unimpaired, and the patient was able, by stopping the aperture of the canula, or by using Brun's canula, to speak, although the voice was raw and hoarse in quality. At the end of a year the patient remained without any indications of a return.

SANITATION OF THE LYING-IN CHAMBER.

At a meeting of the Academy of Medicine in Ireland, Dr. BOXALL, in a paper dealing with the above subject, pointed out that much of the illness following delivery was essentially of a preventable nature. It is not the mortality alone which should be taken into account. Those minor ills of the puerpera, the outcome of less fatal attacks, must be also included. Septic poison can only be produced within the passages where air is permitted to enter, or any decomposable material is left behind; for both the presence of air and a suitable nidus are essential to de-

composition. A special liability, however, exists of the poison, ready made so to speak, finding an entrance from without. Dr. Boxall urged the importance of inquiring into the antecedents of the nurse, with a view to ascertain if she had been nursing or otherwise brought into contact with any person suffering from septicæmia or pyæmia, burns, abscesses, or acute specifics. If exposure have occurred, he advised a complete change of clothing, and a general carbolic or iodine bath. He regarded as the most important element in antiseptic midwifery the thorough washing of the hands with soap and water, including the use of the nail-brush; but he further advised the soaking of the hands and wrists in strong antiseptic solution (sublimat 1 in 1000, or carbolic acid 1 in 20) immediately before making any examination, performing any obstetric operation, or touching the genitals of the patient. Second only in importance to this was the thorough washing and subsequent disinfection of all instruments and utensils employed. The abolition of sponges, and the employment of cotton-wool or tow in place of napkins, he thought beneficial in every way. Special inquiries should be made into the source of all articles passed on from one patient to another, such as binders and mackintosh sheets. Parish bags in use among the poor should always be regarded as likely to contain assorted samples of infection. The condition of the drains should be carefully ascertained, and any defects remedied long before the expected date of the confinement. Too little attention was frequently paid to this point, and also to the subject of ventilation. A fire should be kept burning in the grate, and one window at least opened a few inches at top. With regard to the choice of antiseptic agents, he urged the advisability of employing one of universal applicability rather than several, more especially when incompatibility exists. Sublimate is incompatible with soap (hence the hands must be well rinsed before they are immersed in the solution) and with oils (hence sublimated glycerin or vaseline should be substituted for carbolic oil or lard, as a lubricant); carbolic acid is incompatible with Condyl's fluid, which, again, is decomposed by soap, while iodine enters into combination with the alkali contained in it. These are points which are frequently overlooked. Whatever antiseptic be used, the strength should invariably be measured accurately, for if the proportion be merely guessed at, not only may the solution be so weak that its sepsis-destroying properties

become much deteriorated or are quite destroyed, but, on the other hand, it may be so strong that great danger may result, either locally to the living tissues or generally by absorption, especially when the more powerful agents are employed in the form of douche after delivery. For the hands and instruments he advocated the invariable employment of corrosive sublimate (1 in 1000), or carbolic acid (1 in 20): solutions of the same strength to douche the vagina in every case during the first stage of labor, and after labor subsequently to douche the uterus also, where any intra-uterine interference or foul discharge from the cervix specially indicated such a proceeding. But after the first douche the solution might usually be reduced to half the strength. The sublimate douche frequently administered was not unattended with danger, and he would never advise its use unless the patient were under constant observation. In ordinary cases, when the douche was given as a routine practice, he considered Condy (color of claret) or boracic acid (saturated solution) of sufficient potency. While he invariably advocated the douche (giving morning and evening till the lochial discharge ceases, at from 110° to 115° F.) as a routine practice when the services of a competent nurse are available, he felt sure that in the hands of an ignorant woman more harm than good might ensue. In such a case it was advisable to trust to the more simple details necessary to insure thorough washing and disinfection of the hands and instruments, the exclusion of all sources of infection and of decomposition from, and free ventilation of, the lying-in chamber, and to limit the employment of the douche to the labor, unless special circumstances dictated its subsequent use, and then it should be performed by the doctor in person or under his immediate supervision. Intra-uterine irrigation should never be intrusted to the nurse, however efficient she may be.

DR. INGLE thought Dr. Boxall must have selected an unusual season or place for the statistics given. He did not think the experience of private practitioners would furnish anything near such an estimate, but rather evidence wholly to the contrary. Effort after such sanitation as had been described by Dr. Boxall might be of service in lying-in institutions, with trained skill and careful medical oversight; but in general practice he thought it undesirable that much interference with the parturient should be encouraged other than great cleanliness. Injections of vagina, except specially needed,

were rather to be discouraged, as involving many risks.—*The Lancet*, June 18, 1887.

THE TREATMENT OF EPISTAXIS.

The embarrassment too often created by the persistence with which hemorrhage from the nose continues in some cases, notwithstanding that resort is had to the extreme course of plugging the nares, renders any suggestion for effectually controlling this accident acceptable to practitioners. Its occurrence, moreover, not unfrequently takes place under circumstances that tend to increase the concern naturally aroused by loss of blood so alarming in extent as in many instances it is; very often the surgeon is hurriedly called in to arrest the flow without having been informed of the nature of the illness he is about to attend, and he is consequently unprovided with the special appliances deemed necessary for meeting such an emergency, and this, it may be, at a distance from home much too great to allow of any steps on his part towards procuring the means of easily making and placing in position the plugs with which, as a rule, he would seek to put an end to the bleeding. This question has recently been under discussion at the Paris Academy of Medicine, before which body M. Verneuil has described a method that he is disposed to regard as specific in even grave cases, and which consists in applying over the region of the liver a counter-irritant in the form of a large blister; and he narrated three cases in which this plan of treatment effectually arrested the epistaxis, even after trial with digitalis, ergotine, and plugging had been made in vain. However successful the proceeding may be, it is impossible to regard it as less than a severe remedy, and if a simpler one should prove to be attended with equally good results, the choice, in ordinary cases, would most certainly lie with it.

That such is the case would appear to be the fact from the results claimed by MR. CHARLES H. WADE (*Medical Press*, June 1, 1887), which follows the immersion of the feet and legs of the patient in water as far as possible, and as hot as can be borne. He states that he is indebted for this method to Mr. Jonathan Hutchinson, who found it equal to the needs of all occasions on which he employed it. Mr. Wade also states that he has employed this plan in a number of cases with the greatest success. The success of this process evidently depends upon the abstraction of blood from the head, owing to the

greater demand for it in the lower extremities under the influence of the hot water.

Moreover, it is probable that the force of the outflowing stream through the nostrils being once diminished, coagulation is encouraged in the nasal vessels as a consequence of the loss already sustained, for the tendency, even in obstinate cases of epistaxis, is undoubtedly to the production of clot after a certain period in the process of bleeding. The frequent uselessness of hæmostatics during the flow also points to the same conclusion; for these agents act readily enough when once the loss of blood is arrested, they fail earlier because the effect of their local action is undone by the persistence of a current past the points affected, but which current is slowed or even stopped when a new demand for largely increased supplies of blood is set up in a more dependent part of the body.

It is impossible not to see in the plan of M. Verneuil a close relation to the one described, though the latter has many elements of advantage to recommend a preference for it, at any rate, at first. Whatever opinion may be held as to its mode of action, however, there can be no question of its extreme value as a mode of controlling epistaxis. It is sufficiently simple to be tried in all cases; it will rarely or never fail.

FLUORIDES OF AMMONIUM AND IRON IN HYPERTROPHY OF THE SPLEEN.

Believing on physiological grounds that fluoride salts will probably prove as efficacious in the treatment of chronic splenic hypertrophy as hydrofluoric acid has done in the treatment of bronchocele at the hands of Dr. Woakes, DR. JOHN LUCAS (*Practitioner*, June, 1887) gave the former a trial, and has conducted a series of therapeutic and clinical experiments with these drugs, of which the following is a summary: Certain physiological effects, more or less common to all the cases, were observed. Briefly, there was a marked influence on the blood-pressure, which had a downward tendency at first; the pulse fluctuated and the number of beats was lessened. In this respect Dr. Lucas's experience was quite in accord with that of Dr. Coates. It was also found that the drug possessed antipyretic properties when the temperature ranged above the normal point, and it prevented attacks of ague, thus proving it to be an antiperiodic. Dr. Coates writes that he did not notice this action. In all the cases it

produced nausea at first, though gradually a sort of tolerance appeared to have been established, and the drug could be borne in much larger doses. It produces some intestinal irritation, probably acting more on the duodenum, and giving rise to some diarrhœa. Dr. Lucas is not sure that it has any action as a hepatic stimulant. The appetite after a time improves under its use. Almost all the patients complained of a pricking or twisting pain or uneasiness in the spleen itself, the original pain being sometimes aggravated. When given carefully and after meals, which should be the invariable rule, it is better borne, and does not produce nausea and purging to the same extent. It certainly seems to excel, in reducing the size of the spleen, any other method of treatment with which we are acquainted. It is a new remedy in this connection. Although Dr. Lucas began with small (5-minim) doses, he should be disposed to start with 20 or even 30 minims diluted in an ounce or two of water, and administered always after a meal. The combination of iron with hydrofluoric acid would prove more valuable on account of the hæmatinic properties of the former, and because as an adjunct it would exercise its astringent and tonic influence on the mucous lining of the stomach and intestines, and thus in a great measure tend to counteract the unpleasant effects complained of, and perhaps also to augment the evident specific action on the spleen. The fluoride of quinine can easily be prepared, and so also can the triple fluoride of iron, quinine, and ammonium.

ANTIPYRIN AND ANTIFEBRIN IN HEADACHE AND EPILEPSY.

The use of these two drugs in headache and epilepsy has recently been attracting a certain amount of attention, and we have already laid before our readers the analyses of some recent literature on this subject. In the *New York Medical Journal* for May 28, 1887, DR. ALLAN McLANE HAMILTON extends the experience of his predecessors with the use of these drugs. Some of the cases of headaches in insomnia and epilepsy under his care had already been treated with more or less success with the salicylate of sodium, and the cases of epilepsy were under modified bromide and other treatment.

The cases of headache selected were those of migraine of the angeio-spastic and angeioparetic varieties, as well as ordinary facial or sub-occipital neuralgias; and the cases of

epilepsy which were chosen were those of the symptomatic form complicated with objective and subjective indication of cerebral disease, as well as the simpler forms apparently dependent upon continued states of cerebral ischæmia, cerebral instability, etc.

In angeo-spastic migraine with evidences of cutaneous anæmia, dilated pupils, and coldness, the headache commencing in the morning, Dr. Hamilton found both antipyrin and antifebrin would quickly abort the paroxysms after the first dose.

He reports several cases illustrating the truth of these statements.

In four other cases of epilepsy in which either antipyrin or antifebrin was used there was some improvement in three of the cases, in each of which there was post-epileptic headache; and aggravation of the disease in the fourth, the patient's paroxysms being symptomatic of coarse cerebral disease. In one case of pure hystero-epilepsy the beneficial action of the remedies was absent.

Dr. Hamilton has also used both drugs in cases of habitual insomnia, in doses varying from 3 to 8 grains of the antifebrin, and 10 to 20 of the antipyrin, without appreciable result, though in a case of maniacal excitement, due to nervous exhaustion and connected with moderate rise of temperature (102° F.), 15 grains of antipyrin repeated twice produced refreshing sleep and a subsidence of excitement. There can be no doubt, however, that in wakefulness due to general disease, especially with high temperature, the value of both these drugs as hypnotics is very great.

Dr. Hamilton has at present other patients under treatment, and will subsequently report progress. It would seem as if both remedies were of value in headaches or cerebral states attended by anæmia, or in the excitement due to cell-malnutrition and exhaustion; and, though antipyrin seems to be the more serviceable remedy, it possesses drawbacks which do not belong to antifebrin. It would appear as if the remedies were valueless or even harmful in cases of organic or symptomatic epilepsy, but worthy of a trial in the light cases attended by rather general cerebral vascular spasm and not much muscular movement. In several cases of *petit mal* the good effect of continued doses of antipyrin and antifebrin is manifest, for the losses of consciousness are far less frequent than when the patients were under other treatment. So far as tolerance goes, he has given to one patient 45 grains of antipyrin in two hours without ill effects.

THE USE OF PILOCARPINE IN DISEASES OF THE LUNGS.

RIESS has arrived at the following conclusions, as published in *Schmidt's Jahrbuch*, 1887, No. 5:

The writer believes that the fear that pilocarpine will depress the heart's action is greatly exaggerated, as he has given it in a large number of heart-, kidney-, and lung-diseases, and has never seen severe collapse attend its use. The favorable effect of the drug in pulmonary disease is very little known. Its good effect is dependent upon its property of producing a plentiful fluid secretion in the air-passages, and thus facilitating the removal of inspissated masses formed by chronic hypersecretion.

Riess observed especially good results in chronic bronchitis with scanty, tenacious sputa, and especially where asthma was a complication of emphysema. The dosage with a large number of patients of middle age and well-preserved strength was daily $\frac{3}{10}$ of a grain by hypodermic injection. To old and feeble patients half this amount ($\frac{3}{20}$ of a grain) was given in one dose on alternate days. Dyspnoea was relieved on the first day of administration, asthma was checked, and fine râles were heard over the chest, and free expectoration followed. After from twelve to fifteen injections a very perceptible improvement occurred, which persisted for weeks, and often for more than a month.

Riess also believes that the drug is of the greatest use in asthma. Its good effect is probably produced here by its power to secure the expulsion of crystalline and spiral bodies which form in the finer bronchi, and also to prevent their recurrence. In pneumonia, after the acute stage has passed, resolution may be hastened by pilocarpine. It will also relieve and hasten the spasms of whooping-cough. The dosage has been described. Riess has never given adults more than $\frac{3}{10}$ of a grain at a dose; with children he has never exceeded $\frac{3}{20}$ of a grain. With such doses no especial diaphoresis is produced, and need not be hastened by a warm pack. The subcutaneous method is far the best.

PYRIDINE TRICARBOXYLIC ACID AS AN ANTIPYRETIC AND ANTIZYMOTIC.

Pyridine, as is generally known, is one of the products of coal-tar, and it also occurs in the dry distillation of nitrogenous carbon compounds, and may likewise be obtained

when some of the organic alkaloids are distilled with the caustic alkalis.

According to a statement of DR. C. J. RADEMAKER (*Medical Herald*, June, 1887), pyridine tricarboxylic acid ($C_5H_4(CO_2H)_3$) may be prepared by completely oxidizing quinine by means of permanganate of potassium; filtering the solution from the precipitated carbonate of manganese, and separating the carbonate of potassium from the solution by means of tartaric acid. The solution is again filtered in order to separate the bitartrate of potassium, and evaporated at a low temperature until a pellicle forms and set aside to crystallize.

Pyridine tricarboxylic acid crystallizes in plates with one and a half molecules of water; it becomes anhydrous at a temperature of 115° to 120° ; chars and melts when rapidly heated to 250° , with decomposition; at 180° it already breaks up into carbonic and cinchomeric acid. Pyridine tricarboxylic acid is very soluble in water, but insoluble in alcohol, has a neutral reaction to litmus-paper, and a slightly bitter taste, which is not disagreeable, and does not remain long in the mouth. When this compound is distilled with caustic lime, pyridine distils over. To ferrous sulphate pyridine tricarboxylic acid gives a red color.

Pyridine tricarboxylic acid, when given in doses of 5 grains to cats or dogs, produced marked decrease of temperature and diminished cardiac action without muscular debility. It seemed to have no poisonous effect whatever in these doses. In larger doses it had a still more sedative effect. It produced no derangement of the stomach or bowels, but it slightly diminished the rate of breathing; the only organ that it stimulated was the kidneys; and the drug was readily recognized in the urine by its reaction with ferrous sulphate. This drug also prevents and stops fermentation and putrefaction when commenced, and when a few grains of it are placed in a jar containing the bacillus butyricus and gonococcus they shrivel up and lose their power of reproduction. From its physiological action on the lower animals the conclusion necessarily follows that pyridine tricarboxylic acid is a powerful antipyretic and antizymotic, and that it is indicated in all diseases requiring sedative and antizymotic treatment.

In malarial diseases this drug acts better than quinine; it does not produce that cerebral disturbance, such as ringing in the ears, dizziness, and the so-called quinine intoxication. It is much more readily taken, and produces no derangement of the stomach and

bowels. Ten grains of it will generally suffice to break up the paroxysms. It may be given in solution or pill form. The form in which Dr. Rademaker generally administers it is the following:

R Pyridine tricarboxylic acid, gr. xxxii;
Syrupi aurantii, ℥ii.

M. ft. et Sig.—Teaspoonful every two hours, commencing twelve hours before the expected attack.

But it is in asthma, especially in that form of asthma called spasmodic, that this drug works wonders; 1 or 2 grains administered during paroxysms cuts the attack short almost immediately, and when given before the expected attack it generally prevents the paroxysms. This drug contests every inch of ground with its rival, the iodide of potassium. In asthma depending upon organic lesions it may be considered as inert.

In pertussis, also, this medicine has a power of controlling the paroxysms and cutting short the disease. During the last epidemic of diphtheritis Dr. Rademaker gave this drug a fair and impartial trial in this very dangerous disease, and its administration was attended with such marvellous results that under no circumstances would he resort to any other treatment in the future. Of course local treatment was not neglected.

In typhoid fever, when the temperature rises above 104° F., this medicine acts better as an antipyretic than the cold bath or quinine, the temperature remaining longer lower, and by comparative analysis of the urine there is less waste while this drug is administered. This is his experience of the action of this medicine in not less than one hundred and fifty cases of typhoid fever in the last three years. In hectic, also, this drug diminishes the temperature and gives the invalid a comfortable night's rest. Of course the medicine is not curative in these diseases, but very palliative. And last, but not least, it may be considered a specific in gonorrhœa, when used as an injection, no other treatment being necessary.

SUBCUTANEOUS INJECTION OF COCAINE IN SURGICAL PRACTICE.

In the *Vratch*, No. 50, 1886, p. 892, DR. F. J. BARSKY, of Kharkov, writes that subcutaneous injection of cocaine is extensively used in the clinique of Professor W. F. Grube as an anæsthetic in cases of removal of superficial new growths, such as sarcomata, fibrosarcomata, lipomata, carcinoma of jaw, epithelioma of lip, atheromata, etc.; also in cases of

simple incision, scooping out with a sharp spoon, cauterization, destruction of hæmorrhoids with Paquelin's thermo-cautery, radical cure of hydrocele, removal of foreign bodies (needles, etc.), amputation of fingers, evulsion of nails, rhinoplastic and osteoplastic operations, gouging out bone, etc. The result of those observations may be summed up as follows: 1. An injection of 5 centigrammes of cocaine is sufficient to produce complete anæsthesia of an area measuring from four to six square centimetres. 2. Anæsthesia is complete in five to seven minutes, and lasts from twenty to thirty minutes. 3. Tactile sensibility is preserved, but only to a very slight degree. 4. Artificial local anæmia, produced by pressure with a drainage-tube or otherwise, seems to intensify the anæsthetic effect. 5. The dose used varied between 1 centigramme (a syringeful of a one per cent. solution) and 2 decigrammes (four syringefuls of a five per cent. solution), but those most often employed were 5 centigrammes and 1 decigramme. As a rule, the doses up to 12 centigrammes did not produce any general effects; but in a nervous woman, aged 38, with sarcoma of the parotid gland, 8 centigrammes gave rise to formication and numbness over the body, paleness of the face, giddiness, weakness of the pulse, dryness of the mouth and pharynx, difficulty of swallowing, dyspnœa, oppression in the chest, and vomiting. In a strong peasant, aged 45, with dry gangrene of two phalanges, 1 decigramme produced only dryness of the mouth; 12 centigrammes caused only a slight acceleration of the pulse; 15 centigrammes produced, in from ten to twenty minutes, acceleration and weakening of the pulse, dryness of the mouth, sometimes giddiness and pallor, and once a condition resembling syncope. A dose of 2 decigrammes, in an anæmic girl, aged 13, in whom the os calcis was scooped for caries, gave rise, in fifteen minutes, to dilatation of the pupils, and on the next day to headache and general malaise. 6. Inhalation of amyl nitrite (1, 2, or 3 drops, on a piece of cotton-wool) seems to be the best physiological antidote to cocaine; its action manifests itself very rapidly after a few whiffs. 7. The osseous system, even in its superficial parts, is very incompletely anæsthetized by cocaine. 8. Cocaine has no influence on the process of healing. 9. Cocainization presents many advantages compared with other local anæsthetic agents, the chief ones being rapidity of action, ease of application, harmlessness in regard to the tissues with which the drug

comes in contact, and convenience for use in regions which are inaccessible, or nearly so, to other local anæsthetics. 10. Cocaine will supersede chloroform in many cases, as in cardiac or pulmonary disease, etc., or where the use of chloroform is difficult owing to the position of the patient,—for example, that *à la vache* in operating for hæmorrhoids, etc. Professor Grube and Dr. Barsky have lately tried with success a combination of cocaine with morphine, as recently recommended by Professor Schnitzler.—*British Medical Journal*, June 25, 1887.

IODOFORM INUNCTION IN MENINGITIS.

In the *Practitioner* for May, 1887, MR. R. C. HOLT publishes notes of five cases of meningitis occurring in children, in three of which cases success followed the employment of an ointment containing ten per cent. of iodoform rubbed into the shaven scalp. In the three successful cases the bones of the head had not coalesced, and in all the cases the treatment was not commenced until the disease was well marked. The results appear to encourage the further trial of this treatment, and as soon as possible after the diagnosis is made.

A NEW METHOD OF TREATING LOCAL TUBERCULOSIS.

At a recent meeting of the Society of Physicians of Vienna, KOLISCHER, one of the clinical staff in Albert's surgical clinic, reported his investigations with acid calcium phosphate injected into tuberculous joints. He based his experiments upon the process of calcification, which occurs when tubercular matter becomes innocuous, and reasoned that the agent selected would conduce most to such a process. He also cited cases where an inflammation set up in tubercular joints by fracture or other causes had destroyed the tuberculous process. A concentrated solution was used, because the quantity of dilute solutions required permitted an easy escape of the fluid. Prompt healing of tuberculous joints followed in from four to six weeks. The reaction which was produced was decided as a general rule, but at times was very slight. The difference in the behavior of the tissues led to a division of the cases into two classes,—one in which an inflammatory reaction, which obliterated the tuberculosis, followed promptly; the other, a gradual calcification, resembling the healing of tubercle,

seen in lung-tissue. Where necrosis was in progress it was expedited, and pus and necrosed bone were discharged freely. Enlarged lymphatic glands were observed to rapidly diminish in size, and shared in the contracting process. A peculiar demarcation, resembling the line of gangrene, was observed at the edges of the injection; and ulcers, after the separation of the slough, showed a base of clean, red granulations, which healed very rapidly.

The first case exhibited was that of a girl who had suffered tuberculosis of the elbow-joint. The position had been ankylosis at a right angle. The integument had been very painful and sensitive; the olecranon could not be felt. After injection a stage of reaction and fever followed, succeeded by a period of hardening. Complete absorption followed in three weeks, the possibility of passive motion.

A second case of tubercular joint-disease had also a stage of reaction, hardening, and absorption. There was remaining only a small hard mass, which would soon, Kolischer thought, be absorbed. He had observed that cases in which the process of tuberculosis was most acute responded most promptly to the remedy.

In a third case the site of the disease was the outer site of the ligamentum patellæ; the tubercular tissues had completely disappeared, and the joint was fully restored. While the first three cases had been those of patients comparatively young, the fourth was the case of a well-marked tubercular process in the hand of an adult: the result was also favorable.

In these cases, which were those of ginglymoid joints, it was observed that necrosis of the fascia about the joint occurred; the final result was a more rapid separation of the necrosed fragments and a quicker healing with good motion. In the first of his investigations the reporter made parenchymatous injections of chloride of calcium; this occasioned such violent reactions that it was abandoned; and acting upon the researches of Freund, a Vienna chemist, the solution of calcium phosphate, containing an excess of the phosphoric element, was substituted.

Kolischer thought the phosphoric acid the potent element, and the calcium an adjuvant whose work was not explained.

PROFESSOR ALBERT, in whose clinic the experiments were made, considered the results worthy of careful consideration. In the beginning he had been sceptical as to the re-

sults, but he was convinced that "there are facts new and worthy of consideration." He recalled his experiments in igni-puncture in localized tuberculosis, and said that good results could be thus obtained, but not mobility in diseased joints, which was certainly a great desideratum.—*Wiener Medizinische Blätter*, May 26, 1887.

Reviews.

CYCLOPÆDIA OF OBSTETRICS AND GYNÆCOLOGY: THE PATHOLOGY OF LABOR; THE USES OF ERGOT. Vol. III. of a Practical Treatise on Obstetrics. By Dr. A. Charpentier. In four volumes, two hundred and forty-eight fine wood engravings.

New York: Wm. Wood & Co., 1887.

This volume opens with Part VI., and contains three chapters,—the first on maternal dystocia, the second on dystocia due to the foetus, the third on ergot and its uses. The second chapter contains a section on monstrosities, profusely illustrated, which adds very much to the value of the work. The chapter on ergot and its uses is an exhaustive study of this drug. The author adopts as his own Pajot's law, "As long as the uterus contains anything, be it child, placenta, membranes, clots, never administer ergot." This is very sweeping, and relegates ergot to the museum of defunct drugs, so far as obstetrics is concerned. He gives it simply for inertia, after the termination of the third stage. Now, while ergot should be rarely, if ever, given while the child occupies the uterine cavity, the case of clots is a different matter. Suppose we resolve to turn out the clots, is there any harm in administering ergot before we begin the operation? Do we not gain time in that way and prevent the rapid formation of other clots, remembering that from ten to twenty minutes will elapse after ergot is given by the mouth before its physiological effects are manifested?

While the child is yet *in utero*, the author fears retraction of the cervix; while the placenta is there he fears its retention; with clots he argues in the same way; while in placenta prævia it is far inferior to the tampon. Now, there may be many dangers precipitated by ergot, and as a substitute for the forceps it is certainly a failure, but one who has for many years given ergot freely as the head passes the perineum, and given it as a matter of routine, without finding any difficulty with the placenta, who has given it often before beginning the effort to turn out clots

from the uterus, and has had no difficulty, feels that the danger of the drug is somewhat exaggerated. The editor gives place to diverse views of various American writers on the subject, and himself inclines to the belief that the author is about right. E. W. W.

CYCLOPÆDIA OF OBSTETRICS AND GYNÆCOLOGY: OBSTETRIC OPERATIONS; PATHOLOGY OF THE PUERPERIUM. Being Vol. IV. of a Practical Treatise on Obstetrics. By Dr. A. Charpentier.
New York: Wm. Wood & Co., 1887.

This last volume of the four comprised in the practical treatise on obstetrics is perhaps the most practical and useful. With its profuse illustrations and its aim to cover the whole ground fully, the student will turn to it for a full exposition of the operative treatment of labor. The subject of version in the early chapters is both well described and well illustrated. The second chapter is devoted to the forceps. We have pictured the usual row of obsolete instruments, beginning with Chamberlen's. "Classic forceps" are next described, and at last we come to traction forceps, the development of which is carefully studied from the first instrument of Joulin to the new tractor of Joulin and Poulet, the latter of which is depicted "in action,"—a very proper expression all will agree after seeing the illustration. The Tarnier forceps is studied from its first rudimental form, or rather idea, up to the complete and valuable instrument of today, with its mechanism and the application of its principles to other well-known forceps. The author's "Indications for the Forceps" are sound and progressive. The "conditions requisite for the application of the forceps" are given as four,—a dilated or dilatable os, ruptured membranes, the head presenting, the pelvis not too contracted. But the author does not exclude the applications of instruments to the pelvic extremity. When the hand cannot reach the feet, it is justifiable and its "dangers much exaggerated." If we have a rigid cervix and great urgency, "we must without hesitation nick the external os in several places." The author advises version when the head is above the brim in a small pelvis, but forceps in a deformed one. The only comment the reviewer would make on the section of the book just noticed is, that if the author wrote his views in plain language the translator has failed to make them perspicuous, and the student taking this chapter as a guide must use considerable discrimination.

In applying the forceps the author advises

the French method, to the sides of the child's head, as opposed to the English and German, of applying the blades to the sides of the pelvis. Of course, with the head transverse, this method is valueless, and the other nearly so, and in such cases he applies the instrument with its blades "obliquely both to the head and pelvis" as a compromise measure.

Forced locking of the blades he is absolutely opposed to, or even "rotating them inversely to bring them to the same plane." "The rule should be to begin over, a hundred times if need be." The author treats largely in his description of instrumental extraction of the Tarnier forceps, and its relative advantages and disadvantages. He says of it, p. 107, "It is in particular in the cavity and at the inferior strait that the forceps can be used to the greatest advantage, and here the classic forceps can exert traction better in the axis of the pelvis;" and "at the superior strait the classic forceps and that of Tarnier present the same disadvantages,"—they "cannot make traction backwards." "Do we make traction" with the Tarnier "in the pelvic axis?" he asks. "Not at all at the superior strait, only a trifle in the cavity and at the inferior strait, since it is impossible to know the mathematical axis of the pelvis." This is sad, since these forceps are supposed to do this very thing. He adds, however, "Nevertheless, the younger French practitioners are daily making greater use of the Tarnier instrument," and in England "Alexander Russell Simpson has adapted the principle of axis traction to Simpson's forceps." It was not without cause that we considered the chapter as mixed and misleading. The above quotations will explain the author's state of mind, but will furnish but a poor guide to the inquiring student. The editor, however, comes to the rescue, and condemns the author's views as quite different from his own and those of many others in this country. Indeed, a very brief experience of the Tarnier forceps will, we think, satisfy any intelligent observer that they make backward traction vastly better than forceps of the older pattern. Let the experimenter, after applying them, try making traction with the hands, or with ordinary forceps, and then with the tractors, and see under which effort the most progress is made. Oftentimes a head absolutely unyielding in the former case will, when the tractors are used, descend easily and rapidly.

Chapter v. is upon "the Induction of Premature Labor." The author, after studying the indication for this procedure, describes carefully the many methods advocated by many

men. He prefers over all that of Krause, inserting a gum elastic bougie between the membranes and uterus, and leaving it *in situ* until dilatation is sufficient.

The remaining chapters are on Cæsarian section, Porro's operation, and embryotomy. The last part of the volume, Part VIII., which finishes the work, is upon the "pathology of the puerperium," and contains chapters on the "pathogeny of puerperal fever," "forms of the disease," "pathological anatomy," "prognosis" and "treatment of puerperal diseases." In the last chapter we find the remark made that it appears from experience "that women who have resided in maternities a certain length of time before delivery are less likely to contract puerperal affections than those who enter in labor or a few days before." The former are acclimatized. Throughout the chapter the author's idea of disinfectant processes is confined entirely to carbolic acid. This the editor explains by saying that at the time of writing corrosive sublimate had not yet replaced carbolic acid. Between author and editor the reader will find the whole question carefully discussed, and forming a valuable and proper conclusion to a work of this character. While in many points the author throughout the four volumes is at variance with what is almost axiomatic among us, and in agreement with much that we consider obsolete and outgrown, yet this is not because modern methods and modern thought are unknown to him, but rather because he prefers the old ways to the new, though giving the new generally a fair field, and leaving the reader to decide adversely to himself if he choose. For the book is modern, after all, and out of it may be gleaned many a valuable suggestion and much useful wisdom, which elsewhere might be sought in vain.

E. W. W.

HANDBOOK OF MATERIA MEDICA, PHARMACY, AND THERAPEUTICS. By Saml. O. R. Potter, M.A., M.D. Philadelphia: P. Blakiston, Son & Co., 1887.

The author has aimed to embrace in a single volume the essentials of practical materia medica and therapeutics, and has produced a book, small enough for easy carriage and ready reference, large enough to contain a carefully-digested, but full, clear, and well-arranged mass of information. He has not adhered to any pharmacopœia, as is the case of certain recent manuals, thereby limiting his work, and in this day of new remedies causing constant disappointment, but has brought it up to date in the most satisfactory

way. No new remedy of any acknowledged value is omitted from his list. Under each the section on physiological action and therapeutics has been written with care. Part I. of the volume, devoted to materia medica proper, ends with an elaborate chapter on the "Classification of Medicines." Part II. is devoted to "Pharmacy and Prescription Writing," and contains information which it is very hard to acquire elsewhere than by practical work and precept. Part III., on "Special Therapeutics," consists in an alphabetical arrangement of the diseases and diseased conditions, each being followed with a concise summary of the lines of treatment which have been found of value. This part, while it may strike some as tending to create superficial therapeutists, will be of great service to the already experienced, stimulating the tired brain, and easily recalling forgotten drugs and forgotten methods. In the enumeration of drugs suited to different disorders a very successful effort at discrimination has been made, both in the stage of disease and in the cases peculiarly suited to the remedy. It is no mere list of diseases followed by a catalogue of drugs, but is a digest of modern therapeutics, and as such will prove of immense use to its possessor.

HOW TO STRENGTHEN THE MEMORY, OR NATURAL AND SCIENTIFIC METHODS OF NEVER FORGETTING. By M. L. Holbrook, M.D.

New York: M. L. Holbrook & Co.

How unpleasant to never forget! how annoying to never remember! and that forgetfulness is as useful at times as memory the author admits in his chapter on "The Art of Forgetting." Injuries, for instance, and injustice, disgusting sights, all the unpleasant and little disagreeables of life, are so much better forgotten. Men become pessimists by remembering, optimists by forgetting them, yet a good memory is a very desirable thing. The mind evidently may be well stored, yet wellnigh useless to its possessor if good memory be absent, for memory is the faculty which brings out of the storehouse of the mind what we need, when we need it. The author asks, "How do we remember?" and casts a fine sneer at the physiologist, who speaks of the brain "registering impressions." Yet what else can it do? Did the author ever ponder upon that wonderful toy the "speaking phonograph," and see how it records so minutely and from so little apparently, and reproduces so much? How the dent in the foil, so

nearly invisible, yet possesses the power of throwing back a volume of sound modulated, articulated, and with the recognizable tones of the speaker?

What every one desires is a practical memory suited to his own needs. The memory of the soldier would not suit the historian; the memory of the lawyer might fail the business man. Now, the author thinks that if one follows the lines of study which he indicates he may be reasonably sure of a fairly good working memory.

The question of capacity is one of great practical interest. Does the overwrought child use up and fill with useless things its storage capacity in early life, leaving less room for more important things afterwards? This is a question for the educator, but the educator will never solve it if left to his own devices, for a sort of judicial blindness settles upon him when he begins his work, and deepens as his life goes on. The teacher never sees the overcrowded child, never realizes what the author believes, that fatigue impairs the memory, believes evidently that memory itself is the grand central faculty of mind, and views the parrot with admiration, as the type of all that is good and great in humanity.

Many parts of this book will prove interesting, even to those whose memories are excellent, and who need no additional training. The pages abound in brief but pungent sentences, and indirectly touch upon a multitude of topics of interest. E. W. W.

EVACUANT MEDICATION; CATHARTICS AND EMETICS.

By Henry M. Field, M.D., etc.

Philadelphia: P. Blakiston, Son & Co., 1887.

No matter how great progress man may make in the vast future, he will probably always require some cathartic. Noses may wither away under catarrh, eyes fail from too early and steady use, ears become dull under the incessant clatter of civilized life, teeth vanish as food becomes universally peptonized and malted, but the bowels will remain. The finer the food, the more constipated they will become. The more the brain acts the less will they. Mechanism may make mechanism, and arms may wither, rapid transit may substitute natural locomotion, and legs may dwindle, but still will the compound cathartic pursue its meandering way, and castor oil its sinuous track. He who would prepare for the practice of the future must study cathartics. Purgation will some day be the grand specialty.

In preparing for that day, such books as Dr. Field's "Cathartics and Emetics" are invaluable. The graduate of a day imagines himself skilful in compounding a pill, the aged practitioner considers himself a master of purgatives, but let them read the work of a real master and blush, for in this little book is gathered together all peristaltic lore. By conning its pages one can learn just what purgative to use and just when to use it, the danger, the safety of each, the power and the peril of combination. It is by such practical knowledge of what some call little things that the physician prospers, while the mental giant, the grand, highly-educated product of modern medical study, who has attended the schools of Europe and America, has seen everything and done everything, pines in solitude behind his silver sign and withers day by day. E. W. W.

A TREATISE ON DISEASES OF THE SKIN, WITH SPECIAL REFERENCE TO THE DIAGNOSIS AND TREATMENT, INCLUDING AN ANALYSIS OF ELEVEN THOUSAND CONSECUTIVE CASES. By T. McCall Anderson, M.D., Professor of Clinical Medicine in the University of Glasgow, etc. With colored plates and numerous other illustrations.

Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1887.

The oft-felt need of a full, complete, and yet not too voluminous work on diseases of the skin seems to have been well met by the author of this work. Adopting the classification of Willan, there is given a concise yet vivid description of the various primary and secondary lesions of the skin. Under the heading of classification he divides skin-diseases into the two great classes of functional and organic, and gives an analysis of ten thousand consecutive cases met with in hospital practice. After which we find a further analysis of one thousand consecutive cases met with in private practice. We may remark that in the former, out of ten thousand we find two thousand five hundred and twenty-seven of scabies, while out of the one thousand private cases but forty-four.

Under pruritus the author mentions the pruritus hiemalis of Duhring, a disease which seems to have been universally attributed to the cold weather of cold climates. "It appears to result from cold," the author says, and yet it may possibly result rather from the means taken in cold climates to avoid cold. In so many cases it seems to appear with the putting on of warm woollen garments next the skin and disappear when they are discarded, and with others to be always temporarily re-

lieved by a warm bath; that in the latter it may possibly be due to the cessation of daily bathing. Certainly in most cases the skin will be found dry, not scaly, but smooth and dry, almost polished, and the perspiration tardy in appearing. These cases are often relieved by directing them to wear a thin muslin garment under their winter flannels, next the skin.

In Addison's disease the author describes his own treatment by antistrumous remedies, having noticed how frequently in autopsy the suprarenal capsules were the seat of a scrofulous affection. These measures, combined with blisters over the renal region, have in his hands been of great service in arresting the defect of coloring-matter, clearing up the skin, and improving the general health.

In hirsuties, electrolytic destruction of the hair-follicles offers the only useful means of treatment.

In alopecia areata the author coincides with those observers who have failed to discover a parasitic element, while admitting that the disease "presents all the other characteristics of a parasitic affection." He therefore regards it as a nervous affection. Turpentine and ammonia are the two remedies on which the author relies most.

Under canities we find described a new hair-dye, accidentally discovered by the author, which consists in the use of a solution of bichloride of mercury, gr. ii to \mathfrak{z} i, for a few days, and following with one of sodium hyposulphite, \mathfrak{z} i to \mathfrak{z} i, a few applications making the hair nearly or quite black, without staining the skin or clothing.

The chapter on "Eczema" covers one hundred and nine pages, and is extremely valuable. While believing that in many cases the digestive disturbances so common in eczema are but manifestations of one and the same cause, the author does not deny that eczema may be caused by digestive derangement, and in these cases "the parts most frequently attacked are, as Hebra has pointed out, the face, lips, anus, and hands." Deficient excretion he considers a fruitful cause of the disease, as is also the gouty diathesis and the rheumatic. With regard to the treatment of this affection, the author says, "With some exceptions there are few diseases more curable than even the severe forms of eczema," and "there are many ways of arriving at the same goal." A combination of local and constitutional treatment is generally the best. A long course of purgatives and aperients is

injurious, "except in cases entirely dependent upon digestive derangement." Purgatives may apparently cure many cases, which reappear when they are stopped and flourish "again as luxuriantly as ever." Mercurials are useful in liver torpidity. Small doses of gray powder, combined with rhubarb and salicine or quinine, or sulphate of magnesium, combined with a preparation of iron. When the patches of eczema are indurated, corrosive sublimate in small doses, combined with basle, is sometimes useful, but mercurialization is to be avoided always. The sulphur treatment is less valuable than the mercurial. In functional derangement of kidneys diuretics are useful.

The general internal treatment "radiates in two directions,—for the robust, for the anæmic and strumous." In the latter iodide of iron and cod-liver oil, phosphorus, good food, stimulants, cod-liver oil inunctions. In the robust cases, or those apparently so, local scarification and cupping may be useful, especially if the lower extremities are affected and the patches acutely inflamed. Of nerve-tonics, strychnine and arsenic are the useful ones. The author is not one of those who discard arsenic, like a recent authority, who considers it useless, but he limits its sphere to those who can take it without deranging the digestive organs, without the aggravation of itching and heat, which often occurs in acute eczemas, and would withhold it if herpes occurs until the rash has disappeared. An adult may take 3 to 5 minims thrice a day, and gradually increase. Aggravated irritation of the eyes and puffiness of the face, especially if anorexia, pains in the head and stomach, nausea, and bronchitic irritation appear, are good reasons for diminishing its dose. He quotes Dr. Jas. Begbie, who says, "Arsenic is a remedy too often suspended or abandoned at the very moment when its curative powers are coming into play." There is a great liability to take cold while taking arsenic, and a tendency to the development of bronchitis. During or after meals is the time to take it: in bitter infusion when the stomach is weak; with a little morphine when it provokes diarrhœa. As the disease yields, gradually diminish. The author advises us not to tell our patients that they are taking arsenic.

Alkalies are useful when the patient is addicted to stimulants, and constitutionally inclined to rheumatism or gout. The carbonate of ammonium, in doses of from 5 to 40 grains, three times a day, is the author's favor-

ite. Tar, internally, in doses of from 2 to 40 drops, given in syrup or pill. When given in drops, the author adds to it one-eighth part of rectified spirit, to enable it to be dropped.

The local treatment: first remove all crusts by oil, by poultice, or by vulcanized india-rubber dressings. When itching, swollen, and irritated, dust with the mildest powder, talc, starch, zinc oxide, calcium, or white fuller's earth. Add to any of these a little powdered camphor to "allay the burning heat." Many formulæ are given for soothing ointments. For the chronic condition, potash applications, the various soaps, cold water, always using soft water. For itching, lotions of dilute hydrocyanic acid. In regard to tarry preparations, the author considers them contraindicated when there is any necessity for soothing applications. Tarry lotions, like the inunction of green soap with tar, he considers best of all. Mercurial applications he believes to be of great service; sulphurous preparations seldom are. The oleates evidently find favor with him. The dressings of vulcanized rubber, while occasionally worse than useless, are generally of very great benefit. They also may be used with the various other modes of treatment. For disease of the "ears, brow, nape, and extremities" an ointment of chrysophanic acid is recommended, and for limited eczemas blistering has no rival. The blister employed by the author is a solution of mercurial bichloride 3i to alcohol 3i, or cantharides.

The author's treatment for erysipelas consists mainly in feeding. Quinine and iron he uses as in any other disease, if called for.

In urticaria, where the cause cannot be discovered and avoided, and the eruption continues to crop out, the author thinks that atropine and potas. bromid. pushed to physiological effect are next to be depended on.

We have given somewhat extensively the author's treatment of a few forms of cutaneous disease, but space would fail to mention more. The reader, however, will be attracted more and more by the practical tone of the book and by the author's evident mastery of his subject. We can think of no better work for the practitioner on the subject.

E. W. W.

CHEMICAL LECTURE NOTES. Taken from Prof. C. O. Curtman's lectures at the St. Louis College of Pharmacy. By H. M. Whelpley, Ph.G., etc.

St. Louis, Mo.: Published by the author, 1886.

These notes were evidently first taken for "Quiz" purposes, but, enlarged and perfected,

form the basis for an excellent course of lectures on chemistry. They mirror the actual class and class-room surroundings, the audience, the lecturer, the successful eye-taking experiments. They are well illustrated in regard to the apparatus employed, and would furnish an excellent text-book for a novice in lecturing. To the student these notes will prove useful, and from their form may impress themselves all the more vividly upon the memory.

HANDBOOK OF DISEASES OF THE EAR, FOR THE USE OF STUDENTS AND PRACTITIONERS. By Urban Pritchard, M.D. Edin., F.R.C.S. Eng., Professor of Aural Surgery at King's College, London, etc. With illustrations.

Philadelphia: P. Blakiston, Son & Co., 1886.

A good, compact, and reliable handbook of this kind is always useful, and can always find a place, provided its author knows his subject well and inspires confidence. Too many manuals are the work of babes for babes, the first flight of the medical fledgling ere he soars to more ambitious work. This book, however, is not the production of a novice, and is extremely good, simple, and plain to understand, has good illustrations, as far as they go, can be carried in the pocket, and tells, after all, about all there is on the subject worth while knowing.

E. W. W.

DE L'ENDOMÉTRITE ET DE SON TRAITEMENT. Par J. A. Doléris, Ancien Chef de Clinique d'Obstétrique et de Gynécologie de la Faculté, Accoucheur des Hôpitaux, etc. Paris, 1887.

This brochure of seventy-two pages is a reprint of a series of articles published during the past winter in the *Nouvelles Archives d'Obstétrique et de Gynécologie*, describing M. Doléris's treatment of endometritis.

The author considers the most frequent cause of this disease to be septic infection at parturition or abortion. He does not consider uterine enlargement under the names subinvolution, chronic hypertrophy, hyperplasia, engorgement, and congestion to be the results of a true endometritis; but, holding that there is no inflammation without septic infection, he considers a septic process whose seat is the endometrium, and whose effects are manifested by structural changes in this and related tissues, to be endometritis. Metritis is described as a sequela, and the persistence of endometritis is explained by its analogy to chronic posterior urethritis. The implication of all the tissues connected functionally and anatomically with the uterus, the occlusion of the cervix, which favors reten-

tion of septic matter and produces spasm, and the displacements frequently occasioned, are clearly set forth, as are also the difficulties of spontaneous cure and the many causes militating against recovery. For the restoration of the normal condition of the endometrium he considers local treatment of the uterine surface and dilatation of the cervix indicated. The names and results obtained by those who have used the curette are reviewed, and the writer indicates the grounds upon which he bases his selection of an instrument for a particular case. He follows curetting by the use of the *ecouvillon*,—a spiral brush of varying degrees of stiffness, which he dips in glycerin-creasote, 1 to 3, and with which he cleanses the uterine cavity thoroughly. Antiseptic precautions, the after-use of iodoform and glycerin tampons, complete the treatment.

Especial stress, in the after-treatment, is laid upon maintaining thorough antiseptics in the vagina for a considerable time.

Dilatation of the cervix uteri is not considered indispensable in every case, but is thought very often highly advantageous and indicated. Rapid and gradual dilatation are described, and the advantages of each. For the disinfection of tents and other dilators for gradual dilatation the author has found immersion in a saturated solution of iodoform in ether sufficient. As an intra-uterine antiseptic and escharotic pure creasote in glycerin, 1 to 5 or 1 to 3, is preferred above all others; it is claimed that microscopic examination of tissues acted upon by creasote shows the preservation of their nuclei and their dialysant properties. In feeble solutions, 1 to 10 and weaker, creasote may be used as a general antiseptic. The results of this treatment in three hundred and thirty-nine cases are reported as follows: Endometritis of moderate severity, two hundred and eighty cases; chronic endometritis, with polyoid condition of the endometrium, forty-three cases; recent decidual endometritis, with retention of placenta or membranes, sepsis postpartum, sixteen cases.

The treatment was commenced from three to twelve months after the beginning of the disease; in no case longer than fifteen months.

In the greater proportion of cases the use of the *ecouvillon*, or brush, with creasote, 1 to 10 and stronger, was the treatment; other measures were used as indicated. The author claims that all the cases treated were cured without accident.

E. P. D.

Correspondence.

PARIS.

(From our Special Correspondent.)

Tuberculosis propagated by Hens.—Common justice requires us to mind the health and welfare of the domestic animals whose natural instincts we have perverted to our own purposes; but neglect of such plain duty seems to be often followed by prompt punishment. That several diseases may be spread by the milk of unhealthy cows is a fact now well established; but hens, also, it appears, are apt to catch from man certain maladies, and to propagate them.

Dr. Lamallerée, at the Congress of French Scientific Societies, just held in Paris, related an instance of contagion which derives its chief value from the completeness of the history and clearness of the deductions inferable therefrom. In 1872 a young man, liberated from military service after he had been a prisoner of war, came to a small village, where he settled as a woodcutter. Although suffering from bronchitis, he married a young girl of the locality, but soon after he was taken with hæmoptysis, and died within a year after his marriage, leaving a child, rather delicate. The widow, who had been a strong, healthy girl, gradually became consumptive, so that in 1885 she had cavities in her lungs, profuse expectoration, and now she presents all the symptoms of an approaching end. Dr. Lamallerée was recently called upon to see a neighbor of the widow just mentioned, a young woman whose antecedents could not lead him to suspect tuberculosis. The patient, nevertheless, was found to suffer from incipient phthisis. After long questioning, it was ascertained that within some four months she had eaten eleven chickens bought from her neighbor, and as her strength was failing she had roasted them very slightly, hoping to thus get more nourishment. From her house the doctor stepped into the widow's, whose case he knew well, to ascertain how the hens were fed, how they had died, and whether they were in the habit of absorbing spittles. On this point he received prompt satisfaction. As he was walking into the house he heard the widow have a fit of coughing, and immediately a legion of chickens ran in, as they are wont to do when hearing the voice of the one who feeds them, and began to fight around the bed for the consumptive's spittles. One of the hens having died the same morning, Dr. Lamallerée took it home for examination, and

found in the animal seventeen soft tubercles ; the liver was honeycombed with them, and the liquids contained many bacilli. In the foregoing case three steps of the contagion can distinctly be traced,—1, from man to man ; 2, from man to animals ; and, 3, finally, from animals to man. Before dismissing the subject, a word may be said on another new treatment of tuberculosis, or, rather, a new mode of applying an old medication,—namely, *inhalations of hydrogen sulphide in phthisis*. Dr. Frébault, of the Toulouse Faculty, prefers for obvious reasons the natural gas to that produced in laboratories, and direct contact with the lungs to any other method. He has established at the Luchon Hot Sulphur Springs, directly over the natural outlet, large inhaling-rooms, with appropriate air-circulation, in which patients may breathe the medicated vapor for any length of time that may be considered most beneficial by the medical attendant. It would be out of place here to relate the cures effected. But it is certain that with natural gas there is no danger of arsenical or other contamination to be feared from laboratory products ; the patient has, besides, the benefit of pure country air, change of diet, etc. It must be conceded, also, that the method is one easily applicable to all hot sulphur springs, but the remedy is one that can only be afforded by rich people. The generality of patients may not be in such poor circumstances as the two women mentioned by Dr. Lamallerée, but the number of those who can visit watering-places is necessarily limited.

New anæsthetics are constantly brought to notice, and it must be admitted that those in present use leave room for improvement in more than one respect. At a recent meeting (May 31) of the Academy of Sciences Messrs. R. Dubois and L. Roux presented a memoir on the merits of ethylene trichloride as an anæsthetic. The substance in question, for which they use the name of *methyl-chloroform*,* is a chlorine derivative of ethylene, while ordinary chloroform is a methylene derivative. Its chemical formula is CH_2-CCl_3 , and its ebullition-point 75°C . (167°F .). Methyl-chloroform was, a few years since, tried by Rabuteau on frogs and guinea-pigs, and dismissed as unsatisfactory after some experiments which Messrs. Dubois and Roux consider insufficient and far from convincing.

* This term appears to be a misnomer, and *ethyl-chloroform* more appropriate ; nevertheless, as the memoir relates not to the chemical but to the medical properties of the substance, the name has been retained.

They have experimented with dogs, and are of opinion that the chemical has certain advantages that might prove very useful in human medicine. They are as follows : The boiling-point being higher than that of ordinary chloroform, it saturates less rapidly the air breathed by the subject operated upon. The lower ebullition-point of chloroform, 61°C . (141°F .), is one of the most frequent causes of sudden deaths, as experiments prove that a dog will be killed within five minutes by a mixture of twenty-five per cent. of chloroform vapor and seventy-five of air, while eight per cent. of chloroform may be tolerated by the animal for a whole hour. The odor of the proposed anæsthetic, when pure, is sweet, and not penetrating or suffocating like that of ether and chloroform ; it is not irritating, like chloroform, to the inconvenience of both the patient and the surgeon and assistants, and, unlike ether, burns only with difficulty. The experiments made so far with animals are very satisfactory, and Drs. Dubois and Roux hope to be soon able to complete the investigations necessary before they try the anæsthetic in human medicine.

A question long controverted, is whether *aniline derivatives are poisonous or not*. At first they were decided to be harmful. A little later on, as the poisoning accidents were shown to be due to arsenical impurities, coal-tar colors were simply declared dangerous, owing to the possible contamination. And now that the matter has been investigated closer, poisonous chemicals being avoided in the manufacturing processes, a whole class of the modern colors has been proved to be harmless, while others are only thought to be irritating. Messrs. S. Arloing and P. Caze-neuve have contributed a very elaborate and careful disquisition on a subject which may now be considered as settled, or nearly so. A previous investigation made by M. Caze-neuve, in connection with M. Lépine, had led them to the following conclusions : 1. Although binitro-naphthol is toxic, as is picric acid, its congener, yet its sulpho-conjugated compound N S yellow (sodic conjugated binitro-naphthol yellow) is harmless. 2. Safranin and methyl-blue, without being exactly poisonous, are not quite harmless, as they irritate the intestinal tube. 3. Solid yellow (sodic sulpho-conjugated amido-azo-orthotoluol), roccellin red, Bordeaux red B, purple and ponceau R, orange I (all sulpho-conjugated derivatives of naphthol), and sulpho-conjugated fuchsine, are completely harmless for man, either in good health, or sick even

from Bright's disease. It will probably be noticed that all the harmless colors are sulpho-conjugated sodic combinations. The more recent investigations undertaken by Messrs. Arloing and Cazeneuve, and related at length in the *Revue de Physiologie*, were very searching and extensive. Having examined more especially the *roccellin red* and *Bordeaux red*, they have come to the conclusion that the two colorings in question are not toxic, except when given in very large doses. For instance, a pig took as much as 725 grammes (about 24 troyounces) within one hundred and forty-five days, 5 grammes of *Bordeaux red* being administered daily in the food; the animal thrived and grew fat,—as usual with the porcine species when well fed,—and after death presented no lesion, renal or hepatic, of any sort. Dogs and asses were also experimented with, minute records of the cases being kept, and all the animals proved equally unaffected. Even when the colorings were injected directly into the veins, no intoxication proper could be observed; indeed, some common salts, like sulphate of potassium, for instance, which are considered harmless enough, are more dangerous than sulpho-fuchsine in intravenous injections. As regards the effect on human subjects, a man, aged 30, suffering from myelosclerosis, but with sound urinary organs, took as much as 6 grammes ($1\frac{1}{2}$ drachms) in one day of *roccellin red*; three nephritic patients took 1 gramme (15 grains) of it a day, for eight days, all without any noticeable effects. From the foregoing, Messrs. Arloing and Cazeneuve conclude that, considering the infinitesimal quantities necessary for coloring purposes, the substances in question offer no danger to public health. The legal toleration of 2 grammes of sulphate of potassium to the litre of wine after plastering, is certainly more harmful, and it is proper that legislation respecting aniline colors should be revised.

Pellagra is becoming a sort of national calamity in Italy. It is reported to be now very violent and deadly in Lombardy and Venetia. As customary in such cases, the facts find their way in the foreign medical press, while at home they are carefully kept from the public. The disease is admittedly caused by the inferior quality of the bread, which is heavy, coarse, ill-made, badly baked, and generally supplied but once a fortnight. Within five years eighteen new hospitals have been created for the treatment of *pellagra*, but thousands of poor patients are left without medical attendance of any sort. And

now, to make things worse, the Italian government is preparing a law avowedly intended to impede the importation of American breadstuffs, the inevitable effect of which will be to enhance the price of wheat flour. But a bitter feeling exists against American prohibitory tariffs, and retaliation comes before humanity.

PARIS, June 22, 1887.

APOMORPHINE IN CROUP.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—Croup in young children is such a common disorder that it is generally treated by mothers and nurses with domestic remedies used by *their* mothers or grandmothers before them. It is only when the case becomes alarming and beyond their power that the physician is sent for. Last winter I was called out at night on several occasions to attend such cases. Knowing the valuable expectorant properties of apomorphine, I determined to give it a faithful trial. Dissolving $\frac{3}{8}$ gr. (pellet form) in six teaspoonfuls of water, I administered a teaspoonful every five or ten minutes until emesis resulted. The second or third dose usually did the work. Where the child was past swallowing it was administered hypodermically (of course in less water). I also found vaseline or clean lard or oil rubbed on the chest and throat a valuable adjunct. The after-treatment is of great consequence. Quinine in small doses, with pilocarpine or syrup ipecac, combined with the celery compound, usually filled the bill to admiration. I have lost all dread of croup now if I only have my pellets of apomorphine with me.

Yours truly,

ALEX. F. SAMUELS, M.D.

LA CROSSE, WIS., June 29, 1887.

SANTONIN-POISONING.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In two numbers of the GAZETTE of the present year cases were cited in which serious poisoning was the result of the administration of santonin, having in each instance been given for the expulsion of worms. Will you allow me to add my mite on the subject? For one I am afraid of it, and only rarely use it. It so acts like a balky horse, which, after concluding to go ahead after a spell of stubbornness, will be as likely to smash

the carriage and kill the inmates as to quietly settle down into a respectable canter. The only certain thing about santonin in my hands is that it will poison the patient more or less, and throw the friends into the wildest frenzy. Fortunately, I have never lost a patient from its use. I never give more than 1 grain to a child, nor $2\frac{1}{2}$ grains to an adult, combined with senna or rhubarb, followed in each by the same dose some twelve hours afterwards, and again in the same time by castor oil commensurate with the age of the patient.

My first case of poisoning occurred in my early years of practice, before I had ever heard or knew that such a thing could happen from its use. The child (of 5 years) had violent spasms at short intervals for several hours, unconscious most of the time, and for several days could not see. Her pupils were widely dilated. For safety she was kept in bed, and finally was thoroughly restored, minus forty round worms.

Five years ago, in my dispensary practice, an old Scotchwoman came to my clinic for a cough and severe and constant pain for two years in her right side just below the belt. She was 60 years old, and had grown stout from "lunching in order to quiet the pain." Constipation had become habitual. I gave her some compound liquorice powder, to take a heaping teaspoonful night and morning, and when she reported again in a week's time she brought an open-mouthed bottle with two tape-worms complete, each measuring nearly two yards. Her cough had disappeared entirely. I then ordered santonin in 2-grain powders, with powdered senna, at an interval of twelve hours, and these followed by castor oil. In twenty-four hours her sight was almost destroyed; pupils widely dilated, with sensations as if about to fall, and spasmodic respiration. I at once ordered a large enema of warm water, which produced a very large stool, in which three tape-worms were found, altogether measuring a little over five yards. Immediately her sight returned, but for a week everything was of a deep green color. I had her continue one dose of the compound liquorice powder daily for another week, when everything gradually returned to the natural order of things. She passed in all nine tape-worms, their total length being forty-three feet. In the course of a year her weight was reduced from two hundred and sixty pounds to one hundred and seventy-five pounds, and she became, as she expressed herself, "perfectly well again." I would add that four tape-worms were swollen and in a macerated

condition. This was the only time that santonin ever aided me in my experience to expel tape-worm, and I have tried it frequently for this purpose.

Another case I had only recently. The lady had been voiding long round worms for several years, and she applied to me to rid her of them. I gave her $2\frac{1}{2}$ grains of santonin with 10 grains of powdered senna, repeated in ten hours, each time about an hour after a not very full meal. She grew deathly sick, vomited freely several times, was dizzy, and "out of her mind" for two days; had painful and watery stools repeatedly for three days, and from the first dose everything was the color of an orange; pupils dilated, and limbs quivering. There were no signs of any kind of worms. She recovered completely in ten days.

I regard santonin as a very dangerous remedy, whether prescribed by physician or layman. I am safer (my patients also) with calomel and podophyllin, or senna and spigelia. I have very much doubted my wisdom in using santonin in the case of my old lady, after starting her tape-worms with the liquorice powder.

Very respectfully,

ODELIA BLINN, M.D.

202 WARREN AVENUE, CHICAGO, ILL.

"LOCAL NUMBNESS."

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In the June number of the *Columbus Medical Journal*, 1887, an article appears called "Waking Numbness." Local numbness is a better term, for the reason that in this New Mexican climate the trouble is a very common one, and particularly during the winter and spring months, and on account of the attacks coming on not only during the night but frequently and at any hour during the day. It does not, as a rule, trouble any one during the day when actively exercising. The circulation is not generally disturbed. Motion is not interfered with, at least not in ordinary cases. It seems most frequently to attack the arms; in the lighter attacks but one arm or one limb; it may attack any portion of the body.

The attacks vary in duration from a few moments to several hours, particularly when they come on at night. Although I have seen many cases, and hear of a great number, have not as yet heard of or observed any serious results follow the attacks. I have been on the lookout for more than five years for something

on this subject in the different medical journals which I have come in contact with, not finding the matter discussed until now. I believe I have seen cases where the tongue was attacked, but did not recognize the trouble at the time as this curious neurosis. I have seen at least two extensive and violent cases in this city, both married ladies. Males are not exempt, although I find it much more common among women and more severe. I concluded tonics and stimulants, with local friction during the attacks, would give the best results.

ALBERT E. EALY, M.D.

ALBUQUERQUE, NEW MEXICO,

June 23, 1887.

ANTIFEBRIN AS AN ANTIPYRETIC.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—Dr. Peter J. Martin in the May number of your GAZETTE has an article, with full tables of calorimetrical experiments, also tables of experiments on lower animals, of all the new antipyretics except antifebrin. I read this article with interest. Of late I have tried antifebrin with excellent result, it having a charming effect on my patients. I think it can well be classed with antipyrin and the other antipyretics. So far I think this drug an indispensable article in a physician's armamentarium. On the night of May 17, 1887, my partner was called to J. O., æt. 22, who was suffering from an attack of sporadic cholera morbus, vomiting, purging, and in much pain, and greatly prostrated. He was relieved by ordinary remedies, but for two or three days was weak and pale. The patient said he had eaten some wild honey near some yellow jasmine vines. Before he got strong and thoroughly over this attack he rode some distance in a buggy, and on returning home he got wet. On the afternoon of May 20 I was called to his bedside, and found patient's temperature 105°, tenderness over abdomen, and especially over ileo-cæcal valve, tongue coated, red around edges, and dry. He also experienced pain over lower part of right lung, with a dry, hacking cough; his bowels were loose also. My partner had prescribed quinine in 5-grain doses every four hours, with spts. terebinthinæ, 8 drops three times a day. When I saw him the first time he was in muttering delirium, wandering, etc. I did not change the treatment with quinine for two or three days, but increased the dose. Noticing an increase of head-symptoms, I discontinued the quinine

and ordered antifebrin in 5-grain doses, dissolved in hot water, sugar, and rye whiskey, about 3i altogether. I carefully watched the result, and was delighted with it. It invariably quieted the patient, and in two minutes by my watch he was dozing and in a good diaphoresis; the temperature was reduced on an average of about two degrees in a temperature of 104° or 105°. A pleasant slumber was produced every time it was administered, the action of the pulse was moderated and lessened in quickness. I noticed no depressing effect as I have seen with antipyrin. Antifebrin acted so charmingly in managing the temperature of this patient that later on I only gave it when the patient was restless and wandering in muttering delirium. Of course I nourished and stimulated all the time regularly. I tried, with a great deal of satisfaction to myself and benefit to the patient, Bush's Fluid Food, Bovinine, given with sweet milk. From the time I began the administration of the antifebrin I had very little trouble. The patient is now up and rapidly convalescing after about four weeks' sickness.

I have used antifebrin in several cases of teething children with loose bowels, restless, abdomen hot, and high temperature, where opium had been given to check the bowels. I gave the following prescription:

R Antifebrin, gr. xvi;
Hyd. cum creta, gr. x;
Liquorice powder, gr. xx;
Camphor, gr. xii;
Morphine sulph., gr. i. M.
Ft. in powder No. xvi.

Sig.—One every three hours in good whiskey and sweetened water.

These children have improved and been discharged.

F. W. P. BUTLER, M.D.

EDGEFIELD COURT-HOUSE, S. C., June 4, 1887.

Notes and Queries.

CROTON OIL.

It will be remembered that at an evening meeting in 1878 (*Pharm. Journ.* (3), viii. 705) MR. H. SENIER read a paper in which he reported that he had examined samples of English pressed croton oil that proved soluble in alcohol only in the proportion to the age of the sample, which was contrary to the recorded experience of Pereira and Redwood, and further that the portion soluble in

alcohol exhibited the vesicating property, while the insoluble portion appeared to be inert. Subsequently, in 1883, in another communication (*Pharm. Journ.* (3), xiv., p. 446) Mr. Senier gave his reasons for believing that while the vesicating property of croton oil resided entirely in the portion soluble in alcohol, the purgative property was confined to the portion insoluble. These conclusions not appearing satisfactory to Professor Kobert, the investigation was taken up by Herr von Hirschheydt, a pupil in the University of Dorpat. Upon the basis of the results obtained Professor Kobert now (*Chem. Zeit.*, April 6, p. 416) attributes the activity of croton oil, both as a vesicant and as a purgative, to crotonoleic acid, not to be confounded with crotonic acid, but an acid discovered by Buchheim in 1873, the formula of which has not yet been made out. This crotonoleic acid is said to occur in croton oil both in the free state, in which it is freely soluble in alcohol, and in combination as a glyceride. The glyceride does not possess poisonous properties, but the free acid acts as a powerful irritant to the skin and the intestines (purgative). According to Professor Kobert, the crotonolglyceride is attacked and split up like other glycerides by the ferments of the juices of the stomach, and the crotonoleic acid being set free then exercises its purgative influence. A similar result may be obtained by administering crotonoleic acid as a pill enclosed in keratin. Kobert is not of opinion, however, that the solubility of croton oil is dependent upon the proportion of crotonoleic acid it contains, but considers it to be connected with the age of the oil. Crotonoleic acid may be prepared by treating the portion of croton oil soluble in alcohol with a hot, saturated solution of baryta in a water-bath, washing the stiff white paste that forms with cold distilled water to remove the excess of baryta, and barium compounds with acetic, butyric, and tiglinic acid, removing by heat traces of water, and repeatedly treating with ether, which only takes up the barium oleate and crotonoleate. The crotonoleate is separated by dissolving it out in alcohol, decomposed carefully with sulphuric acid, and the solution containing the free acid evaporated.—*Pharmaceutical Journal and Transactions*, April 30, 1887.

POISONING BY PILOCARPINE.

DR. A. G. GLINSKY, of the Kharkov Alexandrovskaja Infirmary, reports (*Proceedings of*

the Kharkov Medical Society, Part I., 1886, p. 109) a case of poisoning by pilocarpine,—the first of its kind, according to the writer, in medical literature. A gentleman who had been in the habit of using a solution of pilocarpine as a stimulant for the hair swallowed a considerable dose of the fluid instead of a solution of quinine. About five minutes afterwards profuse perspiration, first of the face and then of the whole body, set in, together with salivation. These symptoms were speedily followed by dimness of sight, prostration, trembling of the limbs, a sensation of cold, noise in the head, and a general sense of confusion. On seeing the patient, about an hour after the accident, Dr. Glinsky found profuse, cold, clammy sweat in big drops on the face and body, coldness of the limbs, slight cyanosis of the hands and lips, a sub-normal temperature, pulse 84, full, dicrotic, respirations 14, profuse salivation, great contraction of the pupils, spasmodic shiverings, general restlessness, extreme weakness, and trembling of the lower extremities. The treatment consisted of the internal administration of tannin and emetics, together with the hypodermic injection of atropine ($\frac{1}{8}$ of a grain, given in three doses). A quarter of an hour after the injections a striking improvement took place; the perspiration ceased, the pupils became dilated, and tremor disappeared, and on the following day the patient was quite well. Dr. Glinsky adds that, in the period 1879–85, one hundred and sixty cases of poisoning by twenty-three toxic substances were admitted to the Alexandrovskaja Infirmary. In eighty-five of these, phosphorus matches supplied the poisonous material. He shows by statistics that this kind of poisoning finds an increasing number of victims in Kharkov every year.—*The British Medical Journal*, May 21, 1887.

A CHINESE ANÆSTHETIC.

A curious anæsthetic used by the Chinese has recently been made known by Dr. U. LAMBUTH in his third annual report of the Soochow Hospital. It is obtained by placing a frog in a jar of flour and irritating it by prodding it. Under these circumstances it exudes a liquid which forms a paste with a portion of the flour. This paste dissolved in water was found to possess well-marked anæsthetic properties. After the finger had been immersed in the liquid for a few minutes it could be pricked with a needle without any pain being felt, and numbness of the lips and

tongue were produced by applying the liquid to them.—*The Provincial Medical Journal*, June 1, 1887.

EXPERIMENTAL NEURITIS.

Hypodermic injections of ether are now so frequently employed, and with such good effect, that we are apt to forget that occasionally nervous lesions result from their use. Cutaneous anæsthesia, disorders of motility, and even serious trophic lesions have been observed, and the experimental researches of Arnozan and Salvat proved that the mechanism of these lesions was a peripheral neuritis. MM. PITRES and VAILLARD find, however, that some of the peculiarities of the action of ether on the peripheral nerves must have escaped the attention of the last-mentioned observers. We reproduce the salient points of this interesting communication. When an injection of half a cubic centimetre of sulphuric ether is made deeply into the cellular tissue which separates the muscles on the back of the thigh of a guinea-pig, there always results a paralysis of sensation and motion in the parts of the limb situated below the level of the injection. Generally the anæsthesia occupies the two outer toes and the outer aspect of the leg, but it may sometimes affect all three toes and the whole of the skin of the leg, probably because the injection has traversed the muscular interstices and attacked the crural nerve. After a few days these phenomena may be accompanied by œdematous swelling of the foot, ulceration of the toes and tarsus, falling off of the nails, etc. The anæsthesia and the paralysis are manifested immediately after the injection, and in a short time they have reached their fullest extent, and, once developed, they persist for several weeks, or even months, without either increasing or decreasing in severity. In order to study the mechanism of the action of ether, MM. Pitres and Vaillard have made a histological examination of the segments of the nerve situated above, below, and at the level of the injection of ether, and these examinations have been made on the sciatic nerve from animals after a survival of some hours, days, or several weeks. Above the zone of injection the nerve has always appeared absolutely normal; nothing like an ascending neuritis has been observed. At the level of injection the alterations varied according to the length of survival of the animal. When the nerve was examined some hours only after the injection, the nerve being teased

after maceration for twenty-four hours in a solution of osmic acid, and colored by picrocarmine, eosine, or hæmatoxylin, the myeline is found to have become blackened and rather different from the bluish-black tint of normal nerve-fibres. Further, the lateral fissures are no longer to be seen, the axis-cylinder and nuclei of the interannular segments are not distinct, and it seems as though the nervous elements had become altered in their chemical composition. If the animal be killed six, eight, or ten days after the experiment, the segment of affected nerve shows the same changes; it is only after the fifteenth day that the altered fibres begin to undergo notable modifications; the myeline breaks up, and is slowly absorbed. Below the level of the injection the nervous tubules proceeding from the nerve-trunk affected by the ether undergo the Wallerian degeneration, which is well marked on the fourth day. The ether is therefore regarded as causing an immediate necrosis of the nerve-trunk at the site of injection. This was also shown by an experiment in which the nerve was first divided at its exit from the pelvis, and on the same day ether was injected into the lower part of the thigh of the paralyzed leg. Wallerian degeneration was found eight days after in the nerve, between the point of section and that of injection, and also below the latter, but in the area of injection the nerve had not undergone degeneration; the myeline was continuous and confounded with the axis-cylinder, and there were no traces of nuclear multiplication. Other experiments showed that an injection of the sulphuric ether could arrest the Wallerian degeneration at any point in its career. The same facts hold good with nitric and acetic ethers for guinea-pigs, rabbits, and cats. Hydrochloric ether has less severe effects. Formic and valeric ethers have caused considerable local swellings and gangrene, thus preventing a proper examination of their action on nerves. The authors suggest that, in cases in which neurectomy or neurotomy is needed, injection of ether in the neighborhood of the nerve-trunk might serve equally well.—*The Lancet*, June 18, 1887.

GUACHAMACA TOXIFERA.

Guachamaca toxifera, one of the Apocynaceæ, will probably be restudied. SCHIFFER has already shown its superiority to curare in tetanus, rabies, and psychic surexcitations in general. It acts like curare in paralyzing the

peripheral terminations of the motor nerves, while having no action upon the sensory nerves or the muscles. Nevertheless, it is thought that the alkaloid guachamanine will have a much greater controlling power than curarine. One reason for the prevailing supposition that the alkaloids were chemically identical arose from the fact that they differed from other similar alkaloids in being wholly insoluble in absolute alcohol. According to recent researches by Böhn, curare has another alkaloid,—curine,—which is slightly soluble in water, and dissolves readily in alcohol. He says it, and not curarine, is the active ingredient of the aqueous solutions of curare. A curious fact about curine is that while it is wholly innocuous in doses of 5 to 10 mg., the product of its reaction with iodide of methyl is a poison of very great violence, even in minute doses.—*Pharmaceutical Record*, June 15, 1887.

ANTISEPTIC MIDWIFERY.

In a report by DR. K. INOIEFFS of the work done in the Lying-in Institution in connection with the Golitsinski Hospital in Moscow for the year 1886, the advantage of antiseptic midwifery, which is strictly carried out there, is evident, as out of 541 cases there were but 2 deaths. Some of the statistics, which are very carefully kept, may be of interest. The largest number of births occurred, as it is popularly believed they do, at night, 145 taking place between midnight and 6 A.M.; the numbers corresponding to the remaining three-quarters of the twenty-four hours being 131 from 6 A.M. to noon, 107 from noon to 6 P.M., and 144 from 6 P.M. to midnight. There were 14 abortions and 9 cases of twins; three births took place in the street. Of the remaining 501, 478 were vertex presentations, 15 breech, and 8 transverse. In 9 of the 14 cases of abortion the ovum was removed mechanically. When there was considerable hemorrhage and the os was not dilated, a hot vaginal injection of carbolyzed water was given, which was, as a rule, successful. Twice a plug, consisting of a long strip of cotton wool moistened with glycerin and iodoform, was introduced by means of the speculum, as much as possible being inserted into the cervical canal, and subsequently, when the os was sufficiently patent, the finger was introduced and the uterine contents removed. In one case there was a slight amount of perimetritis, and in two a single rise of temperature. In one

case a spatula was cautiously used to assist the irrigation, and once the contents were removed with the help of a sharp hook. Apart from cases of placenta prævia and abortion, there were 29 cases of hemorrhage, 6 of these occurring in primiparæ; 6 took place during the first and second stages of labor, the rest in the third stage and postpartum. The treatment adopted was, during the first stage, to plug, and when the os was sufficiently dilated to rupture the membranes. If there was rigidity of the os, narcotics were given. When uterine atony was the cause, massage, the application of ether to the abdomen, hot injections, and (after the birth of the placenta) ergot were resorted to. As to operations, episiotomy, or a double V-shaped incision of the perineum, was performed five times, no sutures being inserted afterwards. Twice the os uteri was incised; twice the prolapsed cord was replaced; perineal sutures were required in 20 cases. In the performance of the operation the most careful antiseptic precautions were taken; in 16 cases the union was complete. Retention of membranes required the introduction of the hand into the uterus once, but in 14 cases the placenta had to be artificially extracted, being completely adherent once, and partially so thirteen times. Labor was induced prematurely for contracted pelvis three times, twice by the injection of water at 28° R. (95° F.) through a tube passed into the cavity of the uterus, between the uterine wall and the foetal membranes; in the third case it was induced by the introduction of an elastic sound into the uterus. Podalic version was performed eleven times, and the forceps applied fifteen times. Craniotomy was performed twice.—*Lancet*, May 7, 1887.

DOSE AND USE OF SOME NEW REMEDIES.

Osmic acid: best administered in pill form (made up with Armenian bole). The dose is $\frac{1}{10}$ grain, which may be repeated several times a day. Used in epilepsy and sciatica. Agaricine: best administered in combination with Dover's powder. Dose, $\frac{1}{2}$ to $\frac{1}{4}$ grain. Used for night sweats. Aloin: from $\frac{1}{8}$ grain to $3\frac{1}{2}$ grains, in pill form. Antipyrin: dose, from 75 to 90 grains, divided into three portions, one of which is to be taken every hour. Bismuth salicylate: dose, from 5 to 7 grains, in pill form. In typhoid this dose may be doubled and repeated every hour up to ten or twelve times. Canabinone: from $\frac{1}{2}$ to $1\frac{1}{2}$

grains. Best administered mixed with finely-ground roasted coffee. Sedative and hypnotic. Colocynthin : used subcutaneously. The dose is from $\frac{1}{4}$ to $\frac{1}{2}$ grain. It may also be administered in pill form by the mouth, the requisite dose being from $\frac{1}{4}$ to 1 grain. Convallamine : internally, in pill form. The dose is from $\frac{1}{4}$ to $1\frac{1}{2}$ grains. Euonymin : best given in pill form, combined with extract of belladonna or hyoscyamus. The dose is from 3 to 10 grains. Nitro-glycerin is best given in alcoholic solution. The dose is from $\frac{1}{100}$ to $\frac{1}{50}$ grain, repeated several times a day. Rossbach prefers ether as a solvent. His formula for its use is as follows : dissolve $1\frac{1}{2}$ grains of nitro-glycerin in sufficient ether, and add the solution to a mixture consisting of 2 ounces of powdered chocolate and 1 ounce of powdered gum arabic. Mix very thoroughly, and divide into two hundred pastilles. Each pastille will thus contain $\frac{1}{80}$ grain of nitro-glycerin. Used in angina pectoris, and as a diuretic. Picrotoxin : in aqueous solution. Dose, from $\frac{1}{4}$ to $\frac{1}{2}$ grain. Used in epilepsy. Sulphate of thallin may be given dissolved in wine or water (with some corrigent). The dose is from 4 to 8 grains, or 1 grain every hour. The above is taken in part from the *Rundschau Leitmeritz*.—*The Australasian Journal of Pharmacy*, April, 1887.

MOMORDICA BUCHA.

At a recent meeting of the Paris Biological Society, M. A. DUPRAT made a communication concerning the physiological effects of the *Momordica bucha*, a cucurbitaceous plant of Brazil. The fruit of this plant is prescribed in dropsy. It may be given in injections composed of the watery extract of the fruit, or as a draught prepared from the fruit, after it has been macerated in brandy at 25° C. (77° F.). The injection acts as a drastic purgative, giving rise to severe pain, while the draught causes vomiting. *Momordica bucha* is used only by quacks, and is generally considered dangerous in Brazil. M. Duprat has made experiments with the extract obtained by hydro-alcoholic maceration of the fruit, diluted with water. From these he concludes that *Momordica bucha* acts as a local irritant, causing vomiting and diarrhoea, according to the dose and the manner in which it is administered ; it will cause death if taken in sufficiently large doses. The use of the drug by unqualified persons should be forbidden, but in the hands of medical men it may be very

useful as a purgative.—*British Medical Journal*, May 28, 1887.

COVERING WOUNDS WITH PLASTER.

At an inquest held in the Southwark Coroner's Court last Friday a point was brought out which is of some importance as bearing on the treatment of recent wounds. A school-boy running out of the school-gates fell and cut his forehead. The wound was strapped with plaster, and everything appears to have gone well for four days. Then shivering came on, and was followed by drowsiness deepening into insensibility, and death resulted two days later. After a post-mortem examination, it was decided that the fatal issue was due to blood-poisoning brought on by neglecting to cleanse and dress the wound, the plaster never having been removed from the time of its application. In commenting on cases of this kind one naturally allows somewhat for the possible effects of shock occasioned by the primary injury, which, without amounting to any gross lesion, might yet materially influence the final result. Be this as it may, however, enough has been shown in evidence to enable the coroner to assign to the death in question a more direct connection with the wound itself. The practice of plastering over recent cuts is very usual ; it is also one which in numerous instances has proved injurious. Apart from any question of blood-poisoning, indeed, the mere tension of retained discharges is an inevitable source of mischief where this custom is adhered to. The simple rule in surgery which provides for the free escape of pus where such is likely to form is one of which we need not remind any qualified practitioner. Accidents due to neglect of this rule are chiefly liable to occur when a wound has been treated either by the injured person himself or by a practising chemist. In such cases plaster is the first resource, and is apt to be used rather well than wisely.—*The Lancet*, June 4, 1887.

RICINUS COMMUNIS.

MR. THOMAS DIXSON draws the following conclusion from a paper with the above title published in the *Australasian Medical Gazette* for March and April, 1887 :

1. That the castor oil contains only a gentle aperient, while the castor seeds contain a violent, irritant one.
2. That the seeds should never be used as

is done in some countries by the "herbalist," as aperients, *deaths in great agony having been so caused.*

3. That in castor oil the aperient substance seems to be an oil or resin, and is certainly not the same body which we find in the seeds, after the oil has been extracted, as stated wrongly in text-books.

4. Nauseous material can get into the oil through it being heated, or through it being expressed from the *unshelled* seeds; for the unshelled seeds yield, to alcohol or ether, a brown substance of *ill smell* and acrid taste, but *not aperient*.

5. That if the seeds were shelled before the oil were pressed out cold, an almost tasteless oil is got, while the cake left behind would, if *cooked*, form an albuminous, pleasant article of food, especially of use in India, where *thousands of tons* of the cake are made yearly in a crude way. In *famine*, this would be a *valuable adjunct* to rice, seeing that meat is not eaten by Hindoos.

6. That the active principle is probably the very glycoside found in the seed, which, through a slight change in chemical composition (hydration perhaps), loses its activity (*cf. convolvulin*, which readily changes when heated in presence of alkalies to the inert convolvulinic acid).

The leaves of the castor plant have been long used locally for encouraging lactation. Mr. Dixon was unable to obtain any traces of an active principle, either aperient or otherwise, from the fresh leaves; possibly the benefit may be due to their being large, soft, and pliable, and so suitable for covering the surface well and closely, and encouraging local warmth as non-conductors.

THE LATEST CURE FOR CONSUMPTION.

The recent observations of DR. KOLISCHER upon a new method of treating tuberculous disease of joints, which were described by our Vienna correspondent last week, appear to have excited considerable attention. The method, based on the fact that tubercle deposits do sometimes undergo spontaneous "cure" by calcification and fibroid changes, was an endeavor to excite such retrogressive change artificially. The results obtained in the few cases at present thoroughly treated were certainly striking, and were declared by Professor Albert to surpass any other plan of treatment yet in vogue. It is now said that Dr. Kolischer contemplates applying the

same method to the treatment of visceral tubercle, and once more the world is agitated by the alleged discovery of a "cure for consumption." We would counsel a little patience before accepting even the possibility of being able to artificially arrest the progress of pulmonary phthisis by the administration of acid phosphate of lime or any other salt. At the same time, we would by no means discountenance a fair trial of any plan which, as in this case, is based on rational grounds. Perhaps between the varied efforts to discover germicidal agents on the one hand, and drugs to render the tubercular neoplasm obsolete on the other, we may one day arrive at some panacea. There is not much, however, in the recent history of the treatment of phthisis to render us very sanguine of such a result being attained.—*The Lancet*, June 4, 1887.

THE EFFECTS OF RESORCIN.

From his experience as detailed in the *Journal of Cutaneous and Genito-Urinary Diseases* for June and July, 1887, DR. G. T. JACKSON draws the following conclusions:

Resorcin is an irritating substance for use in eczema, though at times it may prove very efficient in chronic cases where active stimulation is indicated. It exerts a powerful absorptive effect on new cell-infiltrations. It is a useful addition to our list of remedies for the treatment of epitheliomatous lesions where surgical procedures are contraindicated from any cause.

ASTHMA TREATED BY BERGEON'S METHOD.

DR. S. SOLIS-COHEN related before the Philadelphia County Medical Society, May 11, 1887 (*Weekly Medical Review*, May 28, 1887), that he had succeeded in giving immediate relief in a case of asthma through the injection into the intestines of a mixture of carbonic acid and hydrogen sulphide as recommended by Bergeon.

SYRUP OF SACCHARIN.

POLLATSCHKE gives a formula in *Rundschau* (Prag) for making syrup of saccharin. The syrup is used in sweetening medicines for patients suffering from diabetes. Dissolve 10 parts of saccharin and 11 parts of carbonate or 12 parts of bicarbonate of sodium in 1000 parts distilled water at a temperature of 40° C.—*National Druggist*, June 17, 1887.

REST IN THE TREATMENT OF DISEASE.*

By H. C. Wood, M.D., LL.D.†

THE object of the present lecture is to give you such ideas of the endeavors of the physician in the application of rest to the treatment of disease that you may intelligently co-operate with the doctor in charge

* A lecture delivered before the Training-School for Nurses of the Hospital of the University of Pennsylvania.

† Professor of Materia Medica, Pharmacy, and General Therapeutics, and Clinical Professor of Diseases of the Nervous System in the University of Pennsylvania.

of the case. You will remember, I trust, from your early childhood's teaching, that when Adam fell it was announced that by the sweat of man's brow he should earn his daily bread. In these later days we have changed all that, and a great many of the higher portion of man earn their daily bread not by the sweat of the brow but by the toil of the brain. In early childhood, when the little atom of humanity should be out in God's sunlight, he or she is put in school in cramped quarters, leaning over desks and learning lessons, struggling with toil and weariness to develop the brain and nervous system at the expense of the physical powers, if thereby in the future he may climb over some other little atom, who, like himself, has been sacrificed to the

Moloch of culture. As we grow in age this toil ever increases, until at last, when early manhood, or, perhaps, early womanhood, is reached, life is one perpetual nerve-strain. Many years ago, when old Professor Jackson, himself an example of this ruin which is wrought by overstrain, used to lecture to us at the University of Pennsylvania, he taught us this invaluable lesson, that every human being has a certain amount of nerve-force, which is produced by his system daily, and that if more nerve-force than the daily product be used, there will be a continual drawing on the reserve power, until there comes a time when nervous bankruptcy results. It is precisely the same as when a man with a fixed income lives on through the years, spending each year only a little, it may be, more than his income, but, as this continues, at last the capital begins to feel the drain, and, with an accelerated pace, ruin comes on.

Few of us, I think, clearly understand how much of nerve-force it requires simply to live. Remember that the heart beats seventy to eighty times a minute. These great strokes of the central pump must go on through night and day in order that the blood may freely flow through the system. The great tides of air must be drawn in and forced out of the lungs continually, at the expenditure of an enormous amount of nerve-force. When digestion is to be performed, it must be at the expenditure of nerve-force. Most of you have learned from experience this fact, that when you are over-tired a meal will not be digested, which, at other times, you would be able to appropriate without trouble. Many years ago, when a boy, I walked across Chester County from Maryland to the Chester Valley. I had nothing to eat all day, and at night, when we came to a farmer's, he loaded his board down with heavy short-cake. Now, short-cake is a substance that yields only to the digestion of untired boys and ostriches. All through that night and for several weeks afterwards I wished that I had never been born. I had so exhausted myself that there was left no nerve-power to digest this unreasonable food, and, as a result, it underwent fermentation, and poisoning occurred. The heart must act and air must be breathed, but digestion is not absolutely essential, and, consequently, when a man or woman becomes over-exhausted, digestion suffers and no food is taken. When power is failing and strain is greatest, too little fuel is supplied to meet the demand, and so, little by little, this

vicious circle is passed around, until it ends in failure and bankruptcy, which is more and more complete.

Again, often after an acute disease there is left a condition of exhaustion in which the vital powers are not able to supply the needs of every-day life and at the same time accumulate strength. Here, again, rest is necessary.

In health to meet company and associate with our friends adds new life and vigor and power, but the entertainment of people by a woman who is feeble and worn out requires a physical expenditure which is often a great strain. Hence comes the exhaustion of an excessively active social life. Hence it has come that as a central idea of the rest-cure isolation is an important feature. Here there is of course great danger that there shall be rest-cure quacks just as there are quacks with almost every form of special therapeutics. This is a remedial measure which is to be employed with care. It is not a stereotyped and set mould into which every little fragment of exhausted humanity is to be crowded and made to fit whether or not. In some instances it is to be applied with great severity, while in other cases it is only the principles which underlie it that are to be used.

The principle which underlies the rest-cure is, in the first place, the absolute avoidance of all physical expenditure of strength, so that there shall be time for digestion, and so that there shall be opportunity to accumulate the wasted income. One of you lives behind her financial income, and you then go to some hamlet and live in a corner until the income thus saved adds to the capital, and the fortune is restored. This is precisely what the doctor attempts to do when he applies the rest-cure. He puts the patients to bed, keeps them quiet, and does everything to avoid the expenditure of a single unnecessary grain of vital force. He takes that little grain of nerve-energy and uses it to digest a little particle of food, and thereby adds to the exhausted power. It is a very common thing in hungerless patients, put to bed under proper surroundings and kept quiet, to see the appetite return at once. Under these circumstances the appetite is the measure of the deficiency or of the surplus of nerve-power. If there be too little power for nerve-digestion there will be no appetite. When there is a husbanding of the resources the appetite returns.

If a patient is put to bed and allowed to lie there perfectly quiet, then his muscular system is in much the same condition as is that of

the fakir's arm. He ties up his arm, and keeps it so through the decades, and as a result there is a withered, structureless mass without power, the muscular fibre absolutely gone out of it. It is in the muscles of the human being and of the animal that the animal heat is chiefly produced. It is chiefly in the muscular system that are burnt up the effete substances that are the waste of the body, so when the muscles waste the animal heat fails, and the power to destroy effete matters fails. If, then, a patient is put to bed and kept perfectly quiet, there is lack of oxygenation of the tissues, and a gradual loss rather than a gain of power. The importance of rest in the treatment of disease has been long recognized, but it is to the sagacity of Dr. S. Weir Mitchell that we are indebted for the comprehension of the fact that we must not only try to conserve nerve-power, but to also supply power by maintaining the activity of the muscles in such a way that there shall be no draught upon the nerve-centres. If I move my arm there is an impulse flows out from the brain, and, by virtue of this expenditure, the arm is moved. If, however, I apply electrical stimulation, the muscle contracts, the structure of the muscle is maintained, and the activity of the muscle in destroying waste matters is kept up, but there is no expenditure of nerve-power.

Again, where there is no contraction of the muscles, there is a tendency to the accumulation of the juices from the blood in what we may call the by-roads of the system. It is not chiefly the blood that is in the vessels that directly nourishes the body, but the juices that have escaped from the blood that nourish the tissues. Along with every blood-vessel there runs a channel through which these juices that are not used are taken up, carried back into the trunk, and returned to the blood. When the muscles are inactive these little channels become choked up. When I forcibly contract my arm all these little channels are squeezed by the muscles, much as you squeeze a sponge when you take it in your hand. The squeezing of the muscles drives the blood on towards the centre of the body, and also causes the return of these juices to the trunk, and finally to the blood. With absolute rest and quiet there is very little return, and the parts become choked with the half-used blood or flesh-juices. Electrical stimulation causes contraction of the muscles and aids very much in the return of these juices, but it is chiefly single muscles that we pick out by the electrical current. Therefore,

partly for the purpose of aiding in the nutrition of the muscles, and partly for the purpose of returning these juices to the body, we add massage to the electricity. I have gone a little into the details of the principles involved because it not infrequently happens that persons in applying massage make mistakes because they do not appreciate the principles. Sometimes you will see a person rubbing the limb in a downward direction. This is contrary to the direction in which you wish these flesh-juices to go. You do not want to drive them from the arm into the fingers. You want to force them from the extremities to the centre. You continually try to work these juices from the outermost parts and return them to the central portions, where they will soon find their way into the blood.

Under certain circumstances the nurse is called upon to apply electricity. This is always an unfortunate thing, and the treatment sometimes fails on this account, for in using electricity for the purpose of which I am speaking constant judgment is required to know what succession of muscles to cause to contract and also how much of power to employ. It is always much better, where it is possible to do so, to employ some of the younger members of the profession whose time is not as valuable as that of the middle-aged man. I shall not occupy your time with an elaborate discussion of the methods of applying electricity, but shall only call your attention to those parts of the electrical treatment which it is the duty of the nurse to understand. In the first place, it is the duty of the nurse to know how to take care of the battery. There are various forms of faradic batteries, which are the ones employed in this method of treatment, but they all have certain features in common. There is always a cell which contains some acid liquid, into which is plunged a plate of zinc. When the battery is in action the zinc is gradually eaten up by the acid, and the acid is gradually exhausted by the destruction of the zinc, so that the battery destroys itself. The nurse should see that when the battery is not in actual use the zinc is removed from the acid. In the form of battery which I have here the zinc is removed by simply pulling up this rod. In other forms of batteries you have to loosen a screw which holds the zinc, and lift it out and put it into another cup. It is also the duty of the nurse to see that the battery is so kept that there is no spilling of the acid. The nurse should always see that the physician is provided with warm water, in which he can

wet the sponges, and it is well to use a little salt in the water. The water when first brought into the room should be hot, otherwise it may become cold before the séance is over.

With regard to massage, I believe that every thoroughly-instructed nurse should understand it. It, however, cannot be taught by lectures, but must be acquired by personal instruction. I myself know the theory of massage pretty thoroughly, but the practice of it is an entirely different thing. This requires training and the repetition of certain muscular movements until they are done firmly, smoothly, and gracefully. In massage the movements should commence with the fingers. It is well to begin with a rotatory movement in the joints. Then you begin the massage proper. There are three different movements employed,—first, stroking; second, kneading; third, a beating movement, which is made with the fingers acting like so many sticks. The stroking movement is especially directed to driving the juices out of the part operated upon towards the centre of the body. It should be made with the two hands simultaneously. The pressure must be made with the ball of the thumb and the palm of the hand. Before making this movement, if the skin is very susceptible, it should be greased with sweet cocoanut oil, vaseline, or some other unguent. Remember always that this is not rubbing. If you rub a patient, you want to irritate the skin. When you are practising massage you do not want irritation of the skin, but you especially desire to affect the deeper structures. The stroking movement is sometimes made simply with the upward movement of the two hands. It is better to grasp the limb with the one hand above the other. Then you commence the movement with the left hand, and follow it with the right, then slip back with the left hand, while the right keeps up the pressure.

In the kneading movement the effort is made to pick up the individual muscle, and so grasp it between the thumb and forefinger that you roll the muscle on itself. The movement in striking or beating is made with the fingers perfectly loose, and should be made from the wrist and elbow, never from the shoulder. It should be made as rapidly as possible, and carried up the entire limb.

The question of feeding a patient who is undergoing this method of treatment must be decided absolutely by the doctor. It is the nurse's simple business to carry out the directions given by the doctor. The doctor, under

these circumstances,—and I think he should do so in the treatment of all diseases,—should make out a written schedule, so that there can be no possible doubt as to the orders. Some years ago I had an important patient suffering with typhoid fever, who, I believe, was killed by a mistake of the nurse. It certainly was a very distinct solace to me that the orders of the nurse were plainly written. It was absolute carelessness on her part. In all cases of disease the orders for the nurse should be written. A schedule should be made out. We may start at eight A.M. with breakfast. At nine o'clock the bath may be given. In giving the bath it is essential that the patient should be absolutely nude, and she should be put between blankets. The water used should be as hot as can be borne. Unless otherwise directed, it is better to add a little hartshorn or ammonia to the water rather than to use soap. From one-half to one ounce of ordinary aquæ ammoniæ may be added to the small bucketful of water. This will leave the skin soft and in better condition than if soap has been freely used. The bath should occupy about thirty minutes. In most cases the patient is much better if rubbed with ice immediately after the bath or during the bath. This is not to be done unless ordered by the physician. If ordered to rub the patient with ice, you do not take a great iceberg, thrust it on the skin of the patient, and then go to sleep. You take a piece of ice and, with an up-and-down motion, rub it over the limb until the whole surface has been covered. Then dry with a coarse towel. You will find that under this treatment the pale, muddy skin rapidly becomes pink. We have no power equal to this use of hot water and ice in drawing the blood to the surface of the body and in stimulating the skin.

At ten o'clock the patient may have massage. At eleven o'clock milk or some food will probably be ordered. At one P.M. dinner will be taken. Medicines, if employed, are to be put in their proper places. At four o'clock electricity may be employed and a glass of milk given. At five o'clock supper will be given. Seven or eight o'clock will be bedtime. Usually the patient is in bed all the time, but I think patients progress more rapidly if they are permitted to be up a portion of the time.

In making the toilet of these patients never allow them to do up their hair. The great mass of hair which many women have is in itself a labor to comb, and the holding up of the arms is especially tiresome, yet fre-

quently this is one of the points on which patients are most stubborn. In a case of strict rest-cure, you must cut up the food of the patient, and see that the patient does not feed himself or herself. These are the cases in which the method is being used in its utmost strictness. If you have not had definite instructions with reference to these points, ask the physician what he wants you to do.

The hours of the day are twenty-four, but when a person is confined to bed they seem to become forty-eight. In this method of treatment there is so much to be done in the way of bathing, massage, and electricity that much of the time is past without the patient knowing it. There are, however, hours for which it is better to provide some amusement for the patient. I think, therefore, that every nurse, or every nurse who hopes to reach the highest point in her profession, should study the art of reading. The matter read is to be selected by the physician. It is very easy for the patient to tyrannize over the nurse who reads to her. A nurse recently told me that she had to read seven hours to the patient. This is tyranny, and it is the business of the physician to protect the nurse as much as it is his business to protect the patient. There is, perhaps, nothing which develops selfishness more rapidly and thoroughly in human nature than does a long period of chronic invalidism.

What I have been saying to you applies especially to the treatment of chronic disease, but it seems to me to be a matter of importance that you should have a clear idea of the application of the same principles to acute diseases. It also seems to me important, in order that you may be *en rapport* with the medical profession, that you should have some understanding of modern therapeutics and ways of treatment. Therefore I shall at this point branch out a little from the discussion of my main subject, coming back to show you how rest comes into the treatment of all diseases. There was a time when medicine was a purely empirical, dogmatic art. There is of necessity still much of dogmatism and empiricism in the practice of medicine,—that is, we are forced to do certain things because experience has taught us that certain things do good,—but every day are we, as scientific physicians, getting the power of treating disease intelligently and rationally. Perhaps the greatest nuisances that the doctor ever encounters are those amateur doctors, usually, I am compelled to say, of your esteemable sex, who think that they know medicine; the amount of their conceit is in direct propor-

tion to the depth of their ignorance. Under these circumstances you will find that the great stronghold out of which no argument will drive these amateur triflers with life is, "I have seen, and therefore I ought to know." Once I was in the smoking-room of a transatlantic steamer, and there was one of these pestilential creatures there, who this time wore a hat. He was continually bothering me with questions as to the why this and that man had been cured by this or that irregular practitioner after regular physicians had failed. Finally, after I had for some time dodged his questions to the best of my ability, a little Frenchman spoke up, and said to the questioner, "Your talk reminds me of a story." He then told the following story, which I regret that I cannot give in his broken English: "Once in a village there was a shoemaker who was very sick of a fever. Some one who was visiting the wife said to her, 'Your husband has been sick for a long time. I can cure him. Give him as much pork and cabbage as he can eat, and he will get well of the fever.' The next day the woman fed her husband on pork and cabbage, and lo and behold, the fever left the man and he recovered. He put down in his note-book, for future reference, 'Pork and cabbage cures fever.' A few days later there was no ring of the anvil in the village smithy. The shoemaker went to inquire what had become of the blacksmith. He was told that he was sick with a fever. At once he said, 'I know what will cure him. Give him pork and cabbage.' The wife administered pork and cabbage, and the blacksmith incontinently died. The shoemaker, on seeing the symbols of death on his neighbor's house, gets down his note-book to see if there has been any mistake. No, there it is, black and white, 'Pork and cabbage cures fever.' Finally, after rubbing his head awhile, he exclaimed, 'I have got it!' and he wrote in his note-book, 'Pork and cabbage cures shoemakers with fever, but it kills blacksmiths.'"

This pork-and-cabbage style of therapeutics was the only method of treatment of disease forty or fifty years ago; but, thanks to the homœopathic physicians, who emboldened the profession to watch the course of disease without treatment, the regular profession learned this important fact, that most acute diseases have in themselves a tendency to recover. It is the physician's duty to study the dangers which attend the disease and the methods which nature takes to bring about recovery. He should also study the drugs which he has

at his command, and by inductive reasoning apply his knowledge of drugs to his knowledge of the dangers of the disease. To make this clear, let me take you out on the broad Atlantic, where the sunlight is thrown back from every wave as the steamer ploughs the furrows that unite two continents. The captain notes that the mercury is falling. The mate sees a little cloud gathering in the west. To-morrow the hurricane will be upon the vessel. The captain cannot put back the hurricane, but he can make everything snug and tight about the vessel, and he can so turn the helm that the ship goes before the wind. He knows the dangers and avoids them. He goes with the tempest, and does not try to oppose it. This is generally the position of the physician in a case of acute disease. We cannot cure typhoid fever, but we can, if we study typhoid fever properly, carry the ship right on through the tempest and bring it into quiet waters.

The first thing that we learn in studying typhoid fever is, that in the majority of instances it causes death by producing exhaustion. We learn also that sometimes it kills by producing disease of the bowel with ulceration, and that a little particle of solid food getting upon one of these ulcers may tear open the bowel with fatal results. We study the dangers, and see how they are to be avoided. Of all the dangers in typhoid fever exhaustion is the most serious. The successful treatment of typhoid fever rests not upon the administration of drugs, although this may be important, not upon the meeting of this and that symptom as it arises, although the skilful physician does that, but it rests especially upon the fact that the disease has been recognized early, and that every grain of strength has been husbanded, so that in the coming weeks, when it shall be needed, it shall be present. I have often compared a patient with typhoid fever to a ship on a coast in a storm. The ship is being driven on to the point of rocks, but beyond the jutting promontory is smooth water and safety. If the captain can carry the ship around that jutting rock, it makes no difference how close he may come to it, if he but clears it, he is safe. So, in typhoid fever, there often comes a time when it is the last grain of strength that holds the man as he crosses by the edge of the open grave. If you can hold him for a few hours, until a little strength is gained, he is safe. The grain of strength which you as a nurse wasted by allowing the patient to get out of bed three weeks before, may be the

grain of strength which might have carried the man through. In every case of such disease it behooves you to remember that every particle of strength that you can save is perhaps life to that patient. The moment that there comes the slightest indication of the approaching storm the patient should be put to bed, kept quiet, and not allowed to make any motion or exertion. Many a doctor orders absolute rest, and the nurse perhaps thinks that she is carrying out her instructions, and the patient dies because the doctor is careless and the nurse is ignorant. Under these circumstances absolute rest means absolute rest. It means that the patient shall be put in bed, and not allowed to get out for anything. The patient may feel fairly strong, and will insist that he can get out of bed for the natural acts of the body. The patient is to be kept in bed, and under no circumstances, as you value your professional honor, do you let him rise. If the house is on fire, throw him over your shoulder and carry him out, but do not allow him to rise by himself.

Never allow these patients to make their own toilet. If a bath is ordered by the physician which apparently involves a waste of strength, see to it that it is your strength and not the patient's that is wasted. Do not let the patient do anything whatsoever. Do not let him make any exertion. The writing of a letter may mean death. A man may write a letter to his wife which is his own death-warrant.

This application of rest in the treatment of disease goes further. In all diseases the powers of the nurse should be directed to the saving of the strength of the patient, and you should remember that there is a mental worry which is more exhausting than physical exertion. Mere uncleanness, a low voice to a deaf patient, a loud, high-pitched voice to a patient whose hearing is acute, failure to quickly understand the whims and caprices of a sick man or woman, are tormenting things which take away the rest and destroy the life of the patient. We talk about uncleanly nurses, and we all know the type of nurse which was pinned up by Dickens for all ages, as the entomologist pins up the beetle and watches its unclean movements, but the unclean nurse is scarcely as bad as the fussy nurse. In one of the hospitals during the war there was a young soldier who happened to be good-looking and near the door. The majority of amateur nurses that came into the room wanted to do something for him. A young lady came into the room one day and

said, "Can I not do something for you?" "Perhaps," he replied. "Can't I wash your face?" "Yes, if it will give you any pleasure, but you are the thirty-seventh that has done it to-day." A nurse who is continually shifting the blinds, moving about the room when there is no need for it, asking the patient whether he wants this or that, or is excessively active and alert, is a great evil.

Now, nurses of the University Hospital, let me say one more word to you. I think that your calling is one of the highest to which a human being ever devoted herself. You remember that the Bible tells us that "He giveth His beloved sleep;" but sleep is rest. So will you, I trust, comport yourselves that in the future, as you go from house to house, it shall be said of you, "She gave me rest."

THE THERMOGENETIC APPARATUS—ITS RELATION TO ATROPINE.

BY ISAAC OTT, M.D., AND CHARLES COLLMAR, M.D.,
EASTON, PA.

THE phenomena of fever have been divided by Dr. Donald McAllister into thermogenetic, thermotaxic, and thermolytic. We believe the thermogenetic apparatus to be mainly seated in the spinal cord, although it is highly probable that similar centres exist in the brain.

The thermotaxic apparatus located by one of us has its cerebral origin (1) in the tissues about the corpus striatum, (2) Schiff's crying centre, and (3) the anterior end of the thalamus. Its fibres probably decussate about the nib of the calamus, and then run down the lateral columns.*

The existence of the centre about the corpus striatum has been confirmed by the researches of Sachs and Aronsohn,† Girard,‡ and Baginsky.§ They found that electric irritation of the corpus striatum increased the temperature.

Baginsky and Lehmann destroyed the nuclei caudati and found an increase of temperature. It is difficult to state why electric irritation increases temperature if the centre is inhibitory. Usually irritation of an inhibitory centre causes a diminished action of the dependent function.

It is possible, however, that the irritation

of the corpus striatum also irritates sensory nerve-fibres, causing an increase of temperature, the usual result, and thus counterbalances the depression of temperature consequent to the irritation of the caudate nuclei.

Our observations on the spinal cord show that it requires but slight injury on the inner side of the lateral columns to allow increased thermogenetic action, as also does a slight puncture at a distance from the cerebral heat centres.

Sachs and Aronsohn found an increase of both the consumption of oxygen and the excretion of carbonic acid after puncturing the tissues about the corpus striatum.

They also found an increased waste of the albumens of the body, and a twenty-five per cent. increase of nitrogen in the urine.

The animals were previously fed on a non-nitrogenous diet.

Girard also confirmed their observations on the urinary nitrogen.

Richet's statements never became more definite than that the anterior part of the brain cortex, when irritated, caused increased temperature, which was calorimetrically determined to be due to increased heat production.

One of us investigated the brain cortex of rabbits with negative results, conclusions which have been confirmed by Sachs and Aronsohn.

The thermolytic apparatus, or heat-dissipating apparatus, consists of the vaso-motor system, sweat-glands, the lungs, and the reflex action of surface sensory nerves on the thermotaxic or inhibitory apparatus, allowing increased or diminished heat production, according to the requirements of surrounding temperature.

In this paper we wish to advance additional evidence of the existence of spinal heat centres.

Atropine has always been of great value to the physiologist in the elucidation of obscure phenomena.

We have used it in a series of experiments to demonstrate its relation to the thermogenetic apparatus, and found that it causes the temperature of animals to rise, the elevation varying from $1\frac{1}{2}^{\circ}$ F. to 6.8° F.

If a cat be bound down in a warm room, the rise of temperature without atropine will be 2.1° F. in one and three-quarter hours. The animal's efforts to release itself keep up an irritation which corresponds with the condition of affairs when experimenting with the drug.

Cat bound down.

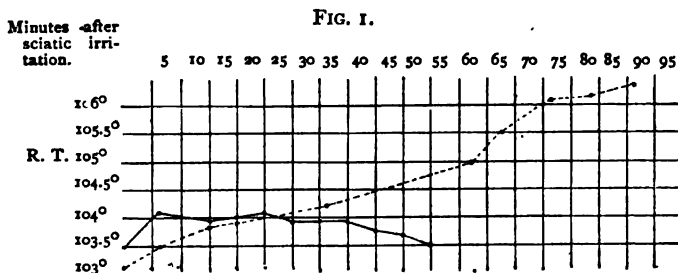

Time. P.M.	Rectal temp.	Air temp.
1.55	101.8°	96°
2.25	102.8°	
2.45	103.1°	
2.55	103.6°	
3.45	103.9°	

If during the rising temperature caused by atropine the central end of the sciatic be irritated, a greater rise ensues, which is followed or not by a fall, but not below the level of temperature existing before the irritation.

Subsequent irritation of the sciatic in Experiment 3 caused no further rise of temperature.

Fig. 1 shows the effect of sciatic irritation on the normal rabbit and atropinized cat, the continuous line marking the rise and subsequent fall which take place in the non-atropinized rabbit, while the dotted line shows the effect of sciatic irritation on the temperature of an atropinized cat.

In the latter the ascent is not sudden as in the normal line, but is gradual, and continues so without falling. If after administering the atropine the cat be allowed to go about the laboratory there will be a rise of temperature, but not nearly as great as when bound down.

In other words, while sciatic irritation in the normal animal, after a preliminary rise, causes a fall of temperature below the normal, atropine prevents a fall below the point attained before the irritation.

It seems that in atropinized cats sciatic irritation is able to cause a great elevation of temperature in a very short time, as in Experiment 3, where the temperature, after a grain and a half of atropine per jugular, sank to 97° F.; from this point on applying sciatic irritation, it rose rapidly to 102° F., a gain of 5° F. in sixteen minutes. (A fair example to show that the gain must be due to increased heat production, as mere diminished dissipation, such as might be caused by vaso-motor contraction, could not occasion such a rise in so short a time.)

The large dose of atropine caused a fall of blood-pressure, and sensory irritation of the sciatic had little effect in increasing the pressure; large doses prevent the sensory irritation from stirring up the vaso-motor apparatus.

Further, in the normal animal, where sciatic irritation causes increased arterial tension, a rise of a degree is about the extent of the effect on the bodily temperature, showing that under atropine the rise must be due to something more than diminished heat dissipation from increased arterial tension.

From this we conclude that the thongs which bind it down act as an irritant similar to the electric irritation of the sciatic. After a dose of atropine the maximum temperature is reached usually at the end of about two hours. Furthermore, the experiments of Von Bezold and Bloebaum show that small doses of atropine elevate the arterial tension and then depress it. Thus we have as a concomitant of a continuously rising temperature, at first a rise of blood-pressure followed by a fall below the normal.

Thus, in Fig. 2, the upper line shows the increasing temperature and the lower line the falling arterial tension.

Ordinarily the increased arterial tension would cause diminished heat dissipation, but our calorimeter experiments demonstrate that during the action of atropine the heat dissipation is increased as well as the heat production.

Hence we infer that circulatory changes have little to do with the rise of temperature under atropine. Atropine also greatly accelerates respiratory movements, but in doing so it makes them more superficial, while in the normal animal bound down the respiration is also much accelerated.

We believe that the rapid respiration also has little effect on the temperature.

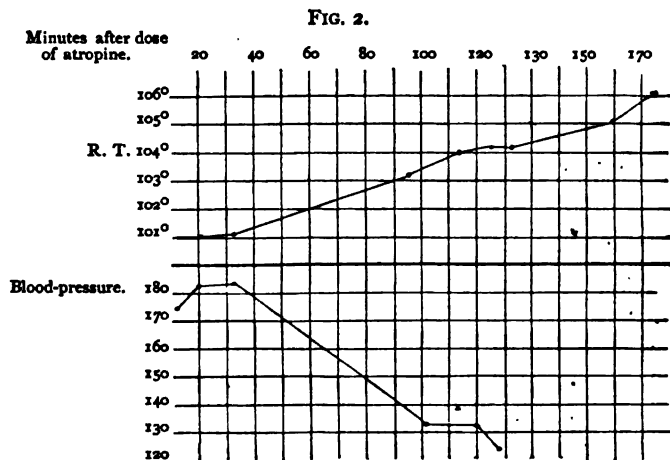

If the rise of temperature is due neither to

circulatory nor respiratory changes, the cause must be seated either in the muscular or nervous system.

As atropine in small doses does not cause convulsions in warm-blooded animals, the source of increased temperature is not in the muscles, with atropine sphincter rhythm appears. Here it must either paralyze the thalamic inhibitory centres, or excite the spinal centres sufficiently to overcome the inhibition, or act on both at the same time so as to weaken the former and excite the latter.

ulant of the spinal cord, evidence in this direction is superfluous.

We believe the increase of temperature to be due to an excitation of the spinal heat centres, and that the irritation of the central end of the sciatic is not able to overcome the spinal stimulation, but rather excites them still more, because the inhibitory centres usually called into activity by sciatic irritation are less active under the drug. This view of the stimulation of the spinal heat centres by atropine is still further strengthened by calorimetric investigations.

That it is dependent on the nervous system is proved by the experiment where the animal was curarized, atropine given, the sciatic irritated, and the surrounding temperature high, yet a rise of temperature ensued. It has also been shown by one of us that at the base of the thalami and the head of the crura cerebri are centres which inhibit the sphincters. When these centres are destroyed a rhythm of the sphincters ensues. Now, if a cat receives a large dose of atropine, irritation of the vagina calls out a rhythm of the sphincter, although the sciatic at the time is strongly stimulated. Usually strong sciatic irritation causes an arrest of the rhythm. Now, this experiment proves that atropine either so excites the excito-motor apparatus of the spinal cord as to overcome the thalamic centres, or it weakens the inhibitory centres of the thalami and in this way starts the rhythm. The sudden starts of the animal upon a noise being made would lend support to the view that the inhibitory centres are weakened. The well-known action of atropine upon the inhibitory apparatus of the heart and intestine also makes us believe the inhibitory centres are weakened at the time the spinal reflex centres are excited. As it is well known that atropine is a great stim-

Both cats and rabbits were placed in D'Arsonval's calorimeter, which is surrounded by felt, feathers, and saw-dust. The temperature of the surrounding air was kept as near as possible within a degree of that of the calorimeter. The sensibility to external heat of our apparatus is $.025^{\circ}$ F. for each degree the calorimeter is below that of the surrounding air, thus giving accurate results.

	Increase of heat production.	Increase and decrease of heat dissipation.
1.....	+ 2.58°	0.°
2.....	+ 2.96°	— 1.88°
3.....	+ 4.42°	+ 3.13°
4.....	+ 7.82°	+ 5.84°

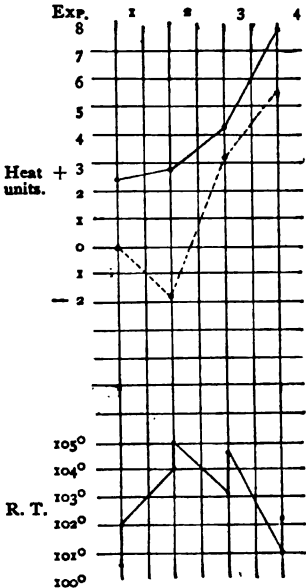

It will be seen by the above table and the curves in Fig. 3, the dotted line showing heat dissipation and the continuous line heat production, that both heat production and heat dissipation are increased, the production more than the dissipation. Hence we believe that atropine increases the temperature by stimulating the thermogenetic centres seated in the spinal cord.

Pathological facts also support this view of the existence of a spinal and cerebral heat apparatus independent of circulatory influence.

Thus, of tetanus, Dr. C. B. Radcliffe* writes, "It is more than difficult to connect the increased heat of tetanus with increased activity of the circulation, or with anything else like fever in the ordinary sense of the word. The temperature rises as the time of death approaches, when the state of the circulation must every moment be becoming more and more the reverse of increased ac-

tivity. The temperature continues to rise even after actual death, when the blood has come to a stand-still. These are the facts, and these being the facts it may be that the increased heat of tetanus may be connected not with increased activity of the circulation, not with true fever, but rather with the contrary state of things.

FIG. 3.

"Nor is it more easy to connect the increased heat of tetanus with the spasms. A part of the increase may be accounted for in this manner, but only a small part. Indeed, the simple fact that in one of the cases which has been instanced a marked abatement in the severity of the spasms was accompanied by an actual rise in the column of mercury, and that the column continued to rise after death, when all spasm is at an end, is in itself a sufficient proof that it is not in muscular action that the explanation of the increased temperature of tetanus is found.

"Moreover, the fact that the temperature rises in the same way before and after death in cases where neither convulsions nor spasms were among the symptoms during life, must lead to the same conclusion."

Dr. Radcliffe's deductions on the temperature of tetanus and the post-mortem rise are entirely compatible with their explanation derived from later knowledge of the heat apparatus,—that is, the cerebral inhibitory centres are paralyzed, and thus permit the spinal thermogenetic centres to assume unchecked activity. In other words, the spinal heat centres behave just as they do after section of the

* Reynolds's "System of Medicine."

lateral columns of the spinal cord, and allow a great increase of activity in them, which causes the increased temperature.

In the light of our researches there is at present no other rational explanation of these facts. Hence our conclusion that atropine causes an increase of temperature by stimulating the thermogenetic centres in the spinal cord, which produces increased chemical activity in the tissues.

COMPARATIVE EXPERIMENTS BETWEEN THE ACTION OF PAPOID AND PEPSIN.

BY DR. D. FINKLER.*

PAPOID is a ferment which is manufactured according to my specification from the plant called *Carica papaya*. It is an albuminous body, which, under certain conditions, can change albumen into peptone. The conditions which produce this change are very different to those under which pepsin and pancreatin produce the same effect.

In order to demonstrate the effect of papoid I shall indicate various experiments made by myself, which will give an exact insight into

the conditions of the effect and also a comparison of the effect of pepsin.

For these comparative trials I used a pepsin of known best quality, most of the commercial pepsin being decidedly weaker than that I used.

First question: Has papoid really a digesting property?

Experiment 1.—*a.* 5 grms. raw meat minced, 50 c.c. water, 5 c.c. of a one per cent. papoid solution (1 gr. in 100 c.c. water). This mixture was put into the oven, and kept for twenty-one hours at 38° C. It was then filtered. The filtered portion contains the albuminous substance of the meat turned into peptone, which is not precipitated by nitric acid, nor by potassium ferrocyanide and acetic acid. It is precipitated by tannic acid, and the xanthoproteic and biuret reactions are well shown. The non-peptonized residue of the meat weighs when dried 0.1 gram.

Therefore ninety per cent. of the solid portions of the meat had been dissolved in water. Of the albuminous substances of the meat eighty-seven per cent. were peptonized, which shows a very energetic degree of digestion.

b. For comparison, 5 grms. raw meat minced, 55 c.c. hydrochloric acid (0.2 per cent.), and 5 c.c. of a one per cent. solution pepsin were treated as above.

After twenty-one hours 70.6 per cent. of the albuminous substance of the meat was peptonized.

Experiment 2.—*a.* 5 grms. meat, 50 c.c. water, 0.5 c.c. of a one per cent. papoid solution.

After forty hours the non-peptonized residue of the meat weighed 0.19 gram.

Of the albumen of the meat 77.7 per cent. was dissolved in the water as true peptone.

b. 5 grms. meat, 50 c.c. hydrochlor. acid (0.2 per cent.), 0.5 c.c. of a one per cent. pepsin solution.

After forty hours the non-peptonized residue weighed 0.19 gram. Of the albumen of the meat 77.7 per cent. was peptonized.

Experiment 3.—*a.* 10 grms. meat, 20 c.c. water, 1.5 c.c. of a one per cent. papoid solution.

After thirty-six hours 73.5 per cent. of the albumen of the meat was changed into true peptone.

b. 10 grms. meat, 20 c.c. hydrochlor. acid (0.2 per cent.), 1.5 c.c. of a one per cent. pepsin solution.

After thirty-six hours eighteen per cent. of the albumen of the meat was changed into true peptone.

* Professor at University of Bonn, Germany.

RÉSUMÉ OF THE THREE EXPERIMENTS.

Ferment.	Digested albumen of the meat.	Time.	Proportion of the quantity of ferment to the meat.	Proportion of the quantity of meat to the liquid.
Papoid 1.	87 per cent.	21 hours.	1 to 100	1 to 10
Papoid 2.	77.7 per cent.	40 hours.	1 to 1000	1 to 10
Papoid 3.	73.5 per cent.	36 hours.	1 to 600	1 to 2
Pepsin 1.	70.6 per cent.	21 hours.	1 to 100	1 to 10
Pepsin 2.	77.7 per cent.	40 hours.	1 to 500	1 to 10
Pepsin 3.	18 per cent.	36 hours.	1 to 600	1 to 2

Papoid therefore shows a more energetic peptonizing power than pepsin, and specially so when the proportion of the liquid to the albumen is small,—i.e., in the proportion of concentration in which food generally exists in the stomach and in the intestines. The great variability in the quality of commercial pepsin (some of which will under the most favorable circumstances not peptonize more than twenty per cent. of the albumen of the meat) gives papoid also the preference, as it is made of one uniform quality.

The peptonizing of hard-boiled egg (albumen) is demonstrated by the following experiments. (The tests were made in an oven at 38° C.)

Experiment 4.—a. 5 grms. albumen (hard-boiled egg), 50 c.c. water, 5 c.c. of a one per cent. papoid solution.

After sixty hours in oven, at 38° C., small residue, peptonized ninety-five per cent.

b. 5 grms. albumen, 50 c.c. hydrochloric acid (0.2 per cent.), 5 c.c. of a one per cent. papoid solution.

After eighteen hours all peptonized,—one hundred per cent.

Experiment 5.—a. 5 grms. albumen, 50 c.c. water, 0.5 c.c. of a one per cent. papoid solution.

After sixty hours all peptonized,—one hundred per cent.

b. 5 grms. albumen, 50 c.c. hydrochlor. acid (0.2 per cent.), 0.5 c.c. of a one per cent. pepsin solution.

After eighteen hours all peptonized,—one hundred per cent.

Experiment 6.—a. 5 grms. albumen, 10 c.c. water, 0.5 c.c. of a one per cent. papoid solution.

After forty-five hours peptonized eighty per cent.

b. 5 grms. albumen, 10 c.c. hydrochlor. acid (0.2 per cent.), 0.5 c.c. of a one per cent. pepsin solution.

After forty-five hours peptonized forty per cent.

Experiment 7.—a. 10 grms. albumen (egg boiled five minutes, rubbed down), 20 c.c. of a one per cent. papoid solution.

After fourteen hours all albumen is dissolved.

Reactions.—1. Boiling only produces a slight precipitate.

2. Xanthoproteic reaction succeeds very well.

3. Biuret reaction also shows very nicely.

4. Acetic acid and potassium ferrocyanide give slight precipitate.

The albumen is therefore all peptonized, one hundred per cent.

b. 10 grms. albumen, 20 c.c. of a one per cent. solution pepsin in 0.2 per cent. hydrochloric acid.

Albumen dissolves slowly. After forty-five hours only fifty per cent. of albumen is peptonized.

RÉSUMÉ OF THE FOUR EXPERIMENTS.

Ferment.	Albumen peptonized.	Time.	Proportion of quantity of ferment to albumen.	Proportion of albumen to liquid.
Papoid 4.	95 per cent.	60 hours.	1 to 100	1 to 10
Papoid 5.	100 per cent.	60 hours.	1 to 1000	1 to 10
Papoid 6.	80 per cent.	45 hours.	1 to 1000	1 to 2
Papoid 7.	100 per cent.	14 hours.	1 to 50	1 to 2
Pepsin 4.	100 per cent.	18 hours.	1 to 100	1 to 10
Pepsin 5.	100 per cent.	18 hours.	1 to 1000	1 to 10
Pepsin 6.	40 per cent.	45 hours.	1 to 1000	1 to 2
Pepsin 7.	50 per cent.	45 hours.	1 to 50	1 to 2

Result.—Hard-boiled egg is better digested by pepsin, if the quantity of liquid is larger in proportion. As soon, however, as a more concentrated mixture is employed superiority of the papoid is at once evident.

Second question: What effect can be obtained by the ferment in the human body?

a. Concentration of the solution is of first importance. It is impossible to create in the stomach and intestines such amount of liquid as would be favorable to the effect of pepsin. The conditions, therefore, are very much in favor of papoid.

b. Importance of the Reaction.—Pepsin acts in the stomach, but not in the intestines as in the latter. The reaction is neutral or alkaline. Papoid has little effect in the stomach, as the reaction there is acid. When, however, the stomach is neutral or alkaline, papoid will peptonize, while pepsin will be useless. The de-

gree (amount) of acid reaction in the stomach differs greatly, especially in case of a stomach out of order; in which case the reaction can be so highly acid or alkaline that pepsin would be of no value at all. In the treatment of stomach-catarrhs we will, moreover, find that, as a general rule, the contents of the viscus have been rendered artificially neutral or alkaline by the administration of remedies, so that in these cases pepsin will have absolutely no effect. Papoid, on the contrary, will act energetically.

c. Regarding the Time available for the Digestive Ferment to act in the Body.—In the case of pepsin this is necessarily very short, as the action ceases when the food enters the alkaline reaction of the intestines. In the case of papoid, which can act well in alkaline reaction, the time is practically unlimited, as it continues acting on the food during the whole time it continues in the body. For all these reasons the conditions for the effect in the human body are far more in favor of papoid than pepsin, and especially as under existing circumstances (high degree of concentration) papoid has been shown to act much more energetically. It is only too clear that the preference should be given to papoid as a digestive ferment for the treatment of dyspepsia. Besides dyspepsia, the papoid is of great importance in the treatment of diphtheria.

Its effective power consists in the circumstances that no free acid need be present in the application, and further that the moisture of the diphtheritic membranes is quite sufficient to allow the ferment to dissolve the solidified substances of the membranes. No other ferment has so far been able to obtain these results. It is on this account that many competent experimentalists and specialists have lately made observations.

From all these circumstances there is no doubt that in papoid we have a ferment which has a great future before it, and it is for this reason that I have made a special study of the manner of preparing the papoid, and I have had the satisfaction of obtaining the most favorable results from its use in the treatment of disease.

THE INFLUENCE OF ANTIFEBRIN, SALICYLIC ACID, AND CARBOLIC ACID ON NORMAL AND ABNORMAL BODILY TEMPERATURE.

BY H. A. HARE, M.D. (UNIV. OF PA.).*

(Continued from page 451.)

III. CARBOLIC ACID.†

THE influence of carbolic acid on temperature in the normal animal has not, that I am aware of, been studied, although Emil Ertl† has found that in mild putrid poisoning it greatly diminishes fever heat, but if the poisoning be severe the acid has no influence.

On glancing at the following tables, which represent the results reached in a series of ten experiments on the normal rectal temperature of rabbits, it is evident that this drug acts much more positively than does salicylic acid, and we find that in every instance there was a fall in the normal bodily heat after the administration of the drug, though in one instance this fall ultimately ended in a rise, which passed above the original and primary temperature of the animal before the injection of the acid.

Experiment 1.—Rabbit; weight, 3 pounds. Gray doe.

Time. A.M.	Drug.	Rec. temp.	Remarks.
11.35	102 $\frac{3}{8}$ °	
11.37	3 drops.	Struggled hard when caught.
11.57	103°	Drug injected hypodermically in 30 minims of glycerin and water.
12.17	102 $\frac{3}{8}$ °	
12.37	101 $\frac{1}{8}$ °	
12.57	101 $\frac{1}{8}$ °	
1.17	101 $\frac{1}{8}$ °	
1.37	101 $\frac{1}{8}$ °	
1.57	101 $\frac{3}{8}$ °	
2.17	101 $\frac{1}{8}$ °	
2.37	101°	
6.15	101 $\frac{1}{8}$ °	Fall of temperature = 1 $\frac{3}{8}$ ° F.

Experiment 2.—Rabbit; weight, 2 pounds. Black and white doe.

* Demonstrator of Experimental Therapeutics and Instructor in Physical Diagnosis in the University of Pennsylvania.

† The carbolic acid used was made by Calvert and was chemically pure, and consisted of the drops obtained from deliquescence of the crystals.

‡ *Schmidt's Jahrbücher*, Bd. clxiv. p. 148.

Time. A.M.	Drug.	Rec. temp.	Remarks.
11.15	103 $\frac{3}{8}$ °	
11.17	2 drops.	Quiet.
12.05	102°	Injected hypodermically in 30 minims of glycerin and water.
12.35	101 $\frac{4}{8}$ °	
1.05	102 $\frac{1}{8}$ °	
1.35	
2.05	102 $\frac{1}{8}$ °	
3.00	102 $\frac{3}{8}$ °	Fall of temperature = 1 $\frac{1}{8}$ ° F.

Experiment 3.—Rabbit; weight, 2 $\frac{1}{2}$ pounds. Black doe.

Time. A.M.	Drug.	Rec. temp.	Remarks.
10.55	103 $\frac{3}{8}$ °	
10.56	2 $\frac{1}{2}$ drops.	Injected hypodermically in 30 minims of glycerin and water.
11.15	102°	
11.35	102°	
12.05	101 $\frac{3}{8}$ °	

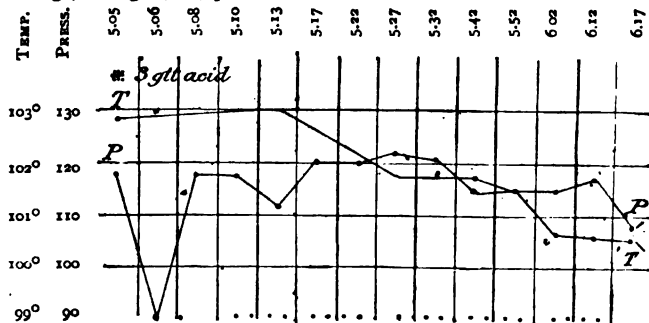

Time.	Drug.	Rec. temp.	Remarks.
12.40	101 $\frac{1}{8}$ °	
1.10	102 $\frac{3}{8}$ °	
1.40	102 $\frac{3}{8}$ °	Fall of temperature = 1 $\frac{1}{8}$ ° F.

These results are likewise supported by the experiments performed to determine the relation between the arterial pressure and the temperature in the normal animal (dogs), in all five of which a fall of temperature occurred. I think we may, therefore, consider proven that this acid lowers normal bodily temperature.

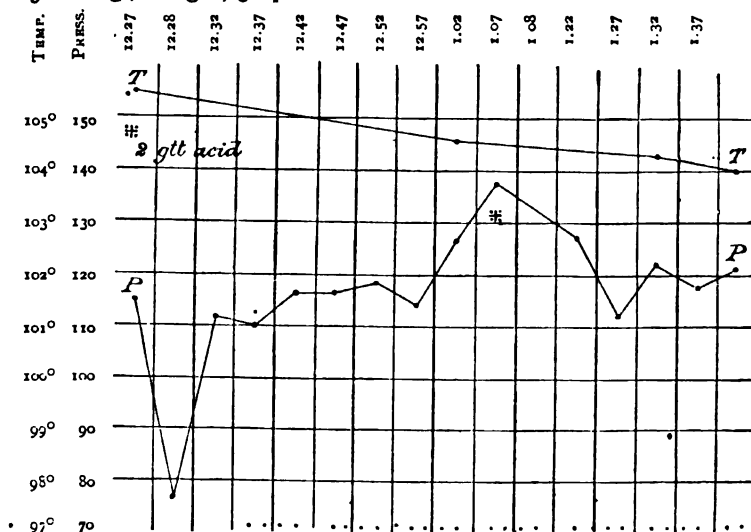

The charts showing the relationship between arterial pressure and the lowering of normal temperature by this drug indicate, at least in part, that there is a fall of pressure *pari passu* with the temperature, although in two of the five experiments the fall of arterial pressure was but momentary, and was followed by a rise. I can give no explanation of this variation. (Two charts left out for want of space.)

Charts showing Arterial Pressure and its Relationship to Temperature, also showing Fall of Temperature produced by Carbolic Acid when that Temperature is Normal.

Experiment 4.—Dog; weight, 14 pounds.

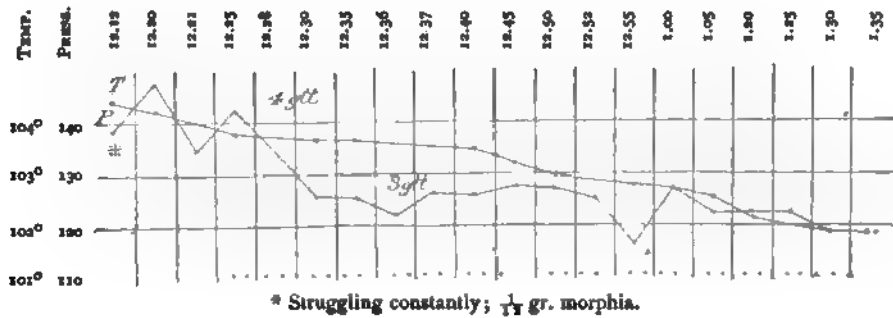

Experiment 5.—Dog; weight, 30 pounds.

* Struggling.

Chart showing Arterial Pressure and its Relationship to Temperature, also showing Fall of Temperature produced by Carbolic Acid when that Temperature is Normal (Continued).

Experiment 6.—Dog; weight, 42 pounds.

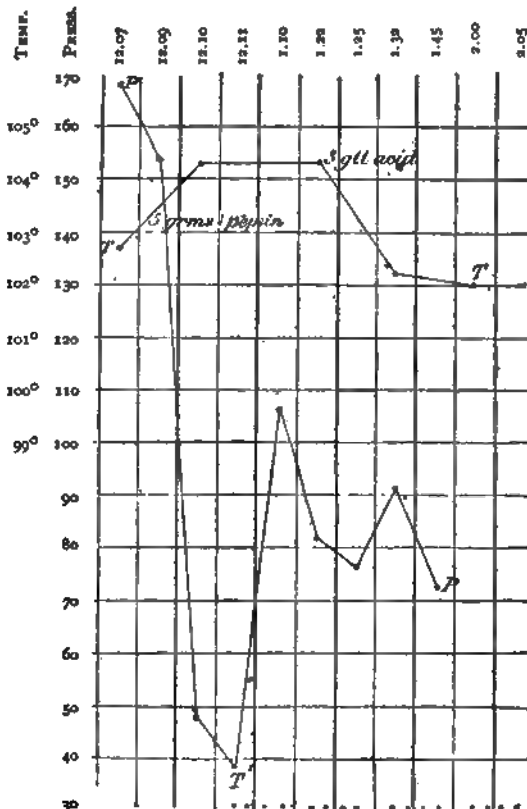

On examining the charts showing the influence of carbolic acid on fever, and the relationship existing between arterial pressure and temperature in fever, we note that in three of the five experiments there was a marked fall of temperature, while in the remaining two there was a rise, or, in other

words, the drug failed to control the pyrexia. In three of the experiments there was a fall of arterial pressure with a fall of temperature, in one there was a rise in pressure with a fall of temperature, and in another there was a fall in pressure with a rise in temperature. (One chart left out for want of space.)

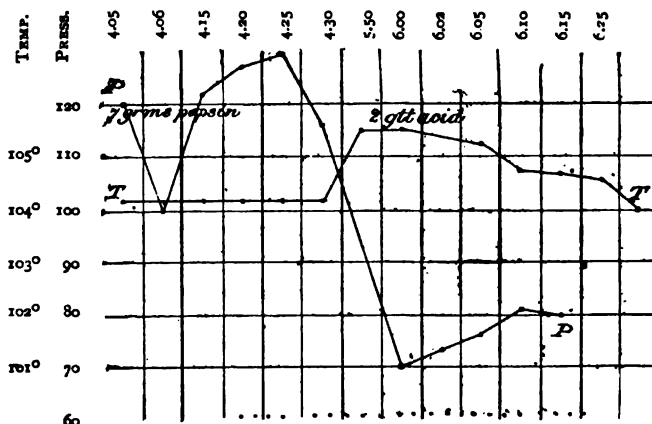

Charts showing the Relationship between Arterial Pressure and Temperature under the Influence of Carbolic Acid in Pepsin Fever.

Experiment 7.—Dog; weight, 19 pounds.

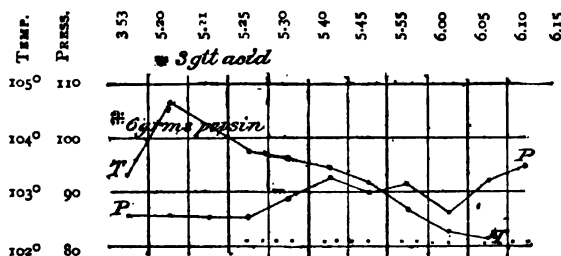

Charts showing the Relationship between Arterial Pressure and Temperature under the Influence of Carbolic Acid in Pepsin Fever (Continued).

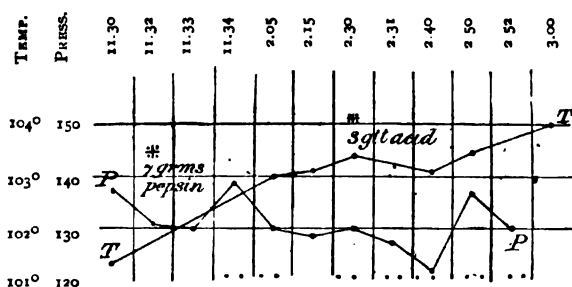

Experiment 8.—Dog ; weight, 25 pounds.

Experiment 9.—Dog ; weight, 26 pounds.

Experiment 10.—Dog ; weight, 20 pounds.

Notwithstanding the fact that the two last named experiments conflict with the first three, I think that we may say that carbolic acid in lowering pyretic temperatures likewise lowers arterial pressure, and this view is strengthened by the results of the experiments performed on normal temperature.

Calorimetrical experiments made to determine in what manner carbolic acid lowers normal bodily temperature are, as might be

expected from the irregular results obtained in the experiments just detailed, not very satisfactory.

It will be noted that in some instances production or dissipation were affected alone or together, while in others one function was decreased while the other was increased.

As the writer used the greatest care in the performance of the experiments there is but little room for fallacy, and, in view of the irregular action of the drug, it would seem

probable that it possesses no particular influence on either function, but may reduce temperature in some instances by acting on both functions.

Result.—Loss of dissipation, gain of production.

The results obtained in the calorimetrical study of this acid on fevered animals are more concordant than those reached in the study on normal dogs, for we find that in Experiments 16, 18, and 19 heat production is very positively decreased, while in every instance where there was no decrease in production there was an increase in dissipation, which, while it did not always amount to a large enough quantity to overcome an increased production, had an effect in lessening the rise in temperature which might come on.

In one experiment, however (No. 20), production was very greatly increased over dissipation, simply because the thermogenic agent caused a rise in temperature which the acid could not affect. It would seem from these experiments that the acid lowers temperature by acting on both heat production and dissipation, the production being generally most affected.

Hourly gain of production after drug..... 74.700

Result.—Both increased, production being more increased than dissipation by a considerable amount.

CONCLUSIONS.

1. Carbolic acid possesses considerable power in lowering normal bodily temperature.
2. It possesses more influence over pyretic temperature than does salicylic acid, generally preventing a rise or causing a fall of temperature, but sometimes failing to do so.
3. Carbolic acid probably decreases arterial pressure when lowering temperature.
4. That its mode of decreasing normal bodily temperature is as yet not fully understood, although it would seem probable that it acts on both heat functions.
5. When influencing bodily heat in fever it acts chiefly by decreasing production, although it affects both functions.

CURIOSITIES OF THERAPEUTICS.

BY G. ARCHIE STOCKWELL, M.D., F.Z.S.,
 PORT HURON, MICH.

III. PRE-HISTORIC AND MYSTICAL MEDICINE.

MOST aptly has it been said that "The proper study of mankind is man." Certainly there has never been offered a problem more abstruse, extended, or difficult of solution than the origin of the human race, and the causes that led to its present mental and physical development. Even those whose orthodoxy is so far above reproach as to spurn the shadows of the doctrine of Evolution as "unclean," do not hesitate to grope among the secrets of the primitive and infinite; and it is no anomaly to discover in the most ardent exponents of a miraculous creation as applied to Life and Intelligence, eager students in the domain of anthropology.

So long as the Assyrio-Chaldaic traditions and anachronisms perpetuated in the Pentateuch* were unreservedly accepted as Divinely

* Not until after the second century was it demanded of human credulity to accept the Pentateuch as the work of the great Hebrew law-giver, or even as of *one man*. The idea originated not among the higher ranks of Christian philosophers, but the more servile Fathers of the Church, whose writings evince they were neither very critical nor very learned persons. The ablest men of every age, Christians and Jews alike, have repudiated these claims, and their decisions have been based upon

inspired history, and a Hebrew "Adam"* deemed both the type and derivative of all humanity and intelligence,—his vocalizations even the foundation of speech and thought,—little was demanded of the mysterious Past. But, when it came to be recognized that the language of Israel is neither primitive nor exclusively derivative; that cosmogonical mensuration could no longer be compressed within the limits of four brief figures; that civilization antedated Scripture and its chronology; that the genealogy of Shem is but a succession of names representing a few out of existing millions of families made to pass before a veil of darkness the momentary liftings of which gave glimpses of great movements that had been long going on behind; that Asia was the seat of mighty empires, and Africa the home of arts and sciences at a time when Noah is accredited with laying the keel of the ark;—a wide vista for study and research was opened, the extent of which even yet is beyond the power of the human understanding to grasp.

For centuries the intelligence of the world has sought in the "Lands of Extinct Monarchies"—Egypt, Arabia, Syria, and Asia Minor—more definite information regarding the early history and development of the human race, ignoring the teaching of geology that the *Western* is the older of the Hemispheres and tropical American latitudes

the intrinsic evidence of the books themselves. These furnish conclusive indications of being derived from two narratives, each distinct and independent, and often contradictory. The claim of Mosaic authorship was not advanced by the early Church authorities, nor did it obtain until deemed essential to the unity of the doctrine of the *Atonement*. Esdras expressly declares the books were written by himself and five others in the space of forty days (2. xiv. 20–44), being led thereto by inspiration and a desire to perpetuate "from the beginning" the history of a race whose records had all been destroyed. True, the writings of Esdras are held apocryphal, but not by any evidence that will withstand modern criticism (see McClintock and Strong's "Biblical, Theological, and Ecclesiastical Cyclopædia," vol. iii. pp. 293–296); indeed, the Hebrews and more intelligent Fathers ever upheld its canonicity. But whether or no, the Pentateuch presents peculiarities that conclusively demonstrate it was composed on the banks of the Euphrates instead of in the deserts of Arabia. It abounds with Chaldaisms, it speaks of the Mediterranean as lying in the *West*, which no Egyptian would do, and the scenery and properties are all Assyrian. (See Draper's "Conflict between Religion and Science," pp. 220–223.)

* Unaccountably the errors peculiar to early and imperfect translation yet persistently obtain. In Genesis, the *Adam* and *ish* of the original Hebrew are accepted as synonymes for *man*, though scholars have long understood the one is discriminative and specific, the

the probable birthplace of terra firma.† Oriental research, in spite of the magnificent results accruing thereto, have ever been unsatisfying as regards evidences of periods antedating those of existing history, and of arts and sciences that were not contemporary with or derived from the Phœnician and Egyptian:‡ the more eager the search, the further removed appeared the bridge that would span the gap existing between early civilization and a primitive nomadism. Such was the status of anthropology up to within the last decade.

Unfortunately, the lifting of the veil was not

other generic. For instance, *Genesis* i. 26, 27, should read, "*Elohim* (God) said, *Let us make Adam in our image, . . . and Elohim created the Adamite* (ha-Adam) *in his own image . . . male and female created he them.*" Subsequently, throughout both the Elohist and Jehovistic narratives, *Adam* with the definite article (*ha*) prefixed is employed exclusively for the descendants of a defined individual. The Hebrew invariably employs *ish* (feminine *ishah*) as descriptive of humanity at large. "*And it came to pass . . . that the sons of God* (Adamites) *saw the daughters of men* (ishah) *that they were fair; . . . and Jehovah said, My spirit shall not strive with the Adamite forever; . . . when the sons of God* (Adamites) *came in unto the daughters of men* (ishah); . . . and it repented Jehovah that he had made the Adamite (ha-Adam) *on the earth* (adamah). . . . Jehovah said, *I will destroy the Adamite* (ha-Adam)," etc. (*Genesis* vi. 2, 3, 4, 6, 7.) Even more marked is the distinction in *Psalms* xlix. 1, the reading of which, as given by competent Hebrew scholars, is, "*Give ear all ye inhabitants of the world, both Adamites and sons of men!*" Those who desire to pursue this topic more critically will find an exhaustive article in one of the earlier volumes of *Scribner*.

† See Sir Charles Lyell's "Principles of Geology." Reber ("History of Ancient Art," p. 1) remarks, "It is a curious chance that the most ancient monuments of human civilization should stand upon a land that is the youngest geological formation of our earth."

‡ The United States, while founding schools of archaeology in Egypt and Greece, has persistently ignored the treasures of the American continents. In the first "Annual Report of the Archaeological Institute of America" it is authoritatively declared that these treasures pertain "to a race that never attained a high degree of civilization," and that has "left no trustworthy records of continuous history." Again, "It was a race whose intelligence for the most part was of a low order; whose sentiments and emotions were confined within a narrow range, and whose imagination was never quickened to find expression of itself in poetic or artistic forms of beauty. *From what it was or what it did, nothing is to be learned that has any bearing on the progress of civilization!*"

This without taking the trouble to make a single examination, and at a time when European scientists, with the reverence true learning begets, were turning their attention to America in quest of the origin of those ancient civilizations which they had been unable to find in countries where they once flourished!

permitted those upon whom the privilege should naturally have fallen, but to able scholars and antiquarians of the "*Old World*" so called, whose eyes were not blinded by the ignorant pretensions of pseudo-science; and the little that has come to us is the sequel of labors of the *Société* and *Congrès des Américanistes*, the archæological department of the *University of Cambridge*, and the individual exertions of Monsieur and Madame Le Plongeon, M. Désiré Charnay, and Mr. Maudslay. Attracted to Central America by the reports of Stephens and Norman, years of toil and hardship have been devoted to the unravelling of the mysteries of Yucatan, Honduras, Guatemala, and Southern Mexico, whereby has been secured an amount of information that is positively startling in its bearings upon history, geography, eschatology, theology, tradition, and art. It gives a better and deeper insight into the sciences, including mathematics, therapeutics, physiology, and psychology; affords a key to mysterious and obscure myths and Orientalisms; and has also unlocked the more secret records of philology. During this period silent and hitherto impenetrable forests were traversed, searched, and forced to yield up the ghosts of a forgotten, mysterious, and progressive civilization; ruins cleared, excavated, ransacked, and photographed; temples, pyramids, palaces, vaults, tombs, tumuli, and astronomical and memorial chambers explored; obelisks and *bas-reliefs* uncovered that rival those of Egypt and Assyria;* languages acquired, hieratic alphabets mastered, and hidden records, and glyphic and other mural sculptures, deciphered and transcribed. In the city of Uxmal was found glyphically inscribed the narrative of Adam and Eve, along with the history of their three sons and two daughters; and both here and at Chichen-Itza numerous other familiar traditions, no longer mere insignificant and fragmentary Hebrew or Assyrio-Chaldean myths without order or sequence, appear as part of the consecutive history of a nation whose existence by some thousands of years antedates accepted chronology. The original of the "Temptation in the Garden" and "Fall of Man"† is told,

* See "Yucatan, its Ancient Palaces and Modern Cities," by M. Augustus Le Plongeon; also, by the same author, "Sacred Mysteries among the Mayas and Quiches;" "The Monuments of Mayax and their Historical Teachings;" "Vestiges of Antiquity;" "Vestiges of the Mayas;" "The Inhabitants of Peru and their Civilization."

† Appendix K.

and none the less valuable because shorn of its Chaldaisms, and the interpretation placed thereupon by Anselm and the superstitious monks and prelates of the earlier centuries of our era;‡ and the fratricidal strife depicted in the fourth chapter of *Genesis* is given not only as a part of this tragedy, but appears to have been the first act thereof.§ The identity of the unfortunate *Abel* of Hebrew literature, *Abal* of the Assyrio-Chaldeans, *Bali* of the Sanskrit, *Balaam* of Petra, *Osiris* of Egypt, and Prince *Coh* of Mayax, is apparently beyond dispute.|| Sculptures of his wife, mother, sister, and children, weeping over his ensanguined corpse and preparing for cremation and the formalities to be paid to his *manes*, appear on the façades of numerous structures; while deep in the interior of a mound, in a sepulchral chamber of hewn and massive stone, was exhumed his statue with tablets of name and rank, the urn containing his heart, the ornaments that he wore, and the blade of flint that struck the fatal blow, all of which are now in the possession either of the National Museum of the Republic of Mexico or of their discoverer.¶

Not the least important of the records brought to light are those that give back to us the great island continent of Herodotus, Solon, Euclid, and Plato, so long deemed fabled, and of which the Azores, Bahamas, Madeiras, Canaries, Cape de Verds, and Lesser Antilles are the mortuary remnants.** Atlan or Atlantis, no longer a myth, is become a glorious reality occupying a place in history, geography, and archæology, second in interest only to that of Mayax itself, since

‡ In the earlier ages of Christianity the story of the "Fall" had not been incorporated as an essential part of the creed of the "Faith." It was Anselm that gave to it the precision as now taught in Protestant and Romish Churches. See "Conflict of Religion and Science," Draper, pp. 57, 222.

§ Appendix K.

|| It is significant, to say the least, that the names of the various personages mentioned in the different accounts of this fratricide are practically identical. See Appendix K.

¶ The manifest value of these treasures historically, as well as their connection with the antiquities of the Republic, was such the Mexican Government would permit only a portion to pass out of the country. The statue of Coh, and the tablets engraved with his titles and rank and appearing as head ornaments, as well as numerous other Maya antiquities (or their copies) referred to in this paper, were viewed by the writer during a recent visit to the "Sister Republic."

** Wyville Thompson's "Voyage of the Challenger." Also Appendix L.

it must needs have been the highway over which passed the germs of those arts, sciences, religions,* traditions, and languages we call our own. That the island was once the scene of human greatness, and the theatre of a civilization superior to that of Egypt in her palmiest days, is already established; and lying exactly in the track of the greatest cataclysms known to our globe, we can readily imagine a convulsion of Nature that would at the same moment engulf a city in Jamaica and another in Portugal, might also submerge a continent.

The discovered hieratic alphabet of ancient Mayax affords convincing evidences of being the derivative of the hieratic characters of the twin civilizations of Egypt and Chaldea, whence was obtained our own written language; and by its aid have been mastered the secrets of the *Troano*, *Popul-Vuh*, and *Cak-chiquel* MSS.,—three of the four sacred books that escaped destruction at the hands of Bishop Landa and his fanatical following when, at the termination of the twenty years' war termed the "Conquest," Rome and the Inquisition undertook to regulate both the temporal and spiritual affairs of "New Spain." We also find that when Uxmal was the political capital of an empire that extended its influence over *three*, and indirectly over *six*, continents, the city of Chichen-Itza was the seat of letters and the metropolis not only of the civilization of Mayax and its dependencies, but of the world. It was the Mecca of science, philosophy, and art, embracing literature, medicine, theology, astronomy, and astrology, and was sought by the wise men of Africa, Europe, and Asia, including India and far away Manchouria and Japan,† that they might sit under the teaching and higher wisdom of the *H-Menes*, or sacred priests. Here progressive Hindus, Thibetans, Mongolians, Aryans, Chaldeans, Ethiopians, Egyp-

tians, Iberians, and Atlans‡ met to worship at the same shrines and altars, and to offer homage to the mysterious deified *Intelligence*, or to sacrifice by casting themselves headlong into the sacred well from which the city derived its name.

Our information regarding the peculiar religious tenets of ancient Mayax is as yet too meagre to admit of definite interpretation or description, though it appears to have been a highly educational form of Theosophism, but triflingly related, however, to the modern doctrine that obtains under this name. By comparing the little knowledge that thus far has been vouchsafed, with that possessed of the faiths of races lower in the scale of civilization, we discover progressive intellectual development by series, the sequence being almost without shadow or flaw.§

‡ The *Troano*, and the sculptures and engraved records unearthed by Charnay, Maudslay, and Le Plongeon, all depict or describe individuals received in Mayax as honored guests, who present vividly many of the race characteristics of our era: bearded Assyrians, or men reminding one of the Afghans of the present; classic Aryans; sensual Egyptians; flat-nosed Ethiopians; and a dark race with red lips possessed of magnificent *physique* supposed to be Atlans, and that would seem to be nearly akin to the Minas of the Benin region (a tribe familiar with the teachings of the Koran and Arabic literature, superior in intelligence to the Arabs, and nothing in common with the negro of the type with which we are most familiar). Among scores of sculptures and statues found by M. Charnay was a negro's head of life-size, perfectly designed even to the curly hair; another, the face of a woman that, save for a battered nose, exactly resembles the present European type, reminding its discoverer of the "Venus of Milo"; and at Tula in the state of Chiapas was unearthed a mould, a cast of which in paraffine exhibited an Aryan beauty with locks arranged in modern fashion, crowned with a braid of false hair. (*North American Review*, Sept. 1880.)

§ The little that remains to us of the history of the *Natchez* and other lower Mississippi tribes, and of the Moquis or Pueblos, is evidence they were intermediates of the existing aborigine and the ancient *Skyris* and *Quichuas* of Ecuador, Bolivia, and Peru,—the latter an offshoot of the *Quiches*; and yet the descendants of Manco Capac (an imitator of the Mayax *Cans*) were not so far advanced in the civilized scale as the Chontales and other non-Maya tribes of Central America, who were yet inferior to the people of Yucatan. The Aztecs more nearly resemble the ancient Quiches. Slavery and Romanism, however, stamped out the last vestiges of civilizations in most respects superior to that of the Latin conquerors. A remnant—now seen in the final stage of reversion to primitivism—yet lingered among the Pueblo tribes who, shaking off the yoke of their oppressors, to some extent escaped the contaminating influence of European immigration, and preserved in part the language, customs, traditions, and religious rites of their early ancestors. This is borne out by the

* The evidences collected by Le Plongeon, Charnay, and Maudslay, and that are verified by the ancient *Troano* MS., have been supplemented by: First, the more recent discoveries by the second-named gentleman, as narrated in the *North American Review* for September, 1880; second, in 1884, some workmen engaged in excavating upon the Caribbean coast of Nicaragua unearthed a huge rock covered with sculptures and glyphs that, when deciphered by experts, were found to be a brief record of the submergence of a vast extent of territory that formerly existed in the expanse measured by the central Atlantic and Saragossa Sea: an event, according to Egyptian authority, that took place somewhere about 9600 B.C.

† Sacred Mysteries of the Mayas and Quiches, pp. 50, 53, 57, 61, 73, 95.

In the *H-Menes*, or pontiffs, of Chichen-Itza is seen an elevated type of the *Quiche* priesthood that in turn ranks higher than the sacerdotal orders of the *Incas*, between whom and the *Shams** of primitivism stand the sacred orders of Zuni. Again, *Kitche-Manit*, or the "Great Spirit" of the nomad,† as the result of broadened intelligence and education on the part of his worshippers and following, had been lifted to a higher plane, becoming more powerful, terrible, and unapproachable, save perhaps to the favored few,—"*the elect*,"—at the same time more munificent and complete. The "*medicine*" lodge,‡ no longer a mere hut, the esoteric wisdoms of which were concealed from the vulgar by the skins of wild beasts or the rinds of trees, is transformed into temples of hewn stone, grand in their massiveness, palatial in their apartments and appointments, and impressive by reason of the knowledge therein hidden, including the rites and ceremonies sacred alike to Deity, philosophy, and art. And the ordeals, though less savage, less vulgar, were become even more severe and appalling with each step that approached the unknown and carefully guarded "*Holy of Holies*"; the initiations were calculated to progressively educate, and yet test to the utmost the physical and intellectual capacity and endurance of those who sought the closest possible communion with the mysterious power deified as the "*Supreme Intelligence*."§

little Mr. Frank Cushing has revealed to us of the *Mysteries* yet practised among the Zunis, to which he has been admitted. Of course, I do not pretend to say these peoples and races, *all*, are absolute links in the chain, but merely *typical* of such links.

* THERAPEUTIC GAZETTE, April, 1887, p. 234.

† Ibid., p. 229.

‡ Ibid., p. 236.

§ See Appendix M; also the scriptural record of *Enoch* and *Melchizedek*. It is an open question whether the man that "*walked with God*" and subsequently "*was not*," is not identical with *Malki-Tse-dek* (*Melchizedek*). Evidently both were high pontiffs of the *Mysteries* in some part of the world, whether in the plains of Arabia or groves of Mayax. *Enoch*, *Chanok*, or *Hanoch*, as the word is variedly rendered, means simply "*Initiated*," and *Malki-Tse-dek* a "*Priest of Elyon*," or "*First among the Holy*." Says Rev. Dr. McClintock, "There is something surprising and mysterious in the first appearance of Melchizedek and in the subsequent reference to him. Bearing a title which would in after-ages be recognized as that of a sovereign, bringing gifts which recall to Christians the Lord's Supper, this Canaanite crosses for a moment the path of Abraham, and is unhesitatingly recognized as a person of higher spiritual rank than '*The Friend of God*.' Disappearing as suddenly as he came, he is lost to sacred writings for a thousand years, and then a few emphatic words bring him into sight as a type of the

In the sacred temples or colleges was inculcated the majesty and greatness of the *Supreme* in Nature and in Art, and likewise of the existence of a *power* between, or a psychic essence emanating therefrom, superior to Life and Matter! To reach this power and render it amenable to and a part of the understanding, was the high aim of the *Mysteries*, the pathway being progressive knowledge and intelligence. In no sense were the colleges schools of pagan polytheism, save, perhaps, indirectly. While adoration was paid the celestial bodies, the mastodon,||

coming of the Lord of David. . . . The faith of early ages continued to invest his person with superstitious awe, and a mysterious supremacy came also to be assigned to him, because of his having received gifts from the Hebrew patriarch." ("Biblical, Theological, and Ecclesiastical Cyclopædia," vol. vi. p. 87.)

Enoch, or Cān-ok, was the son of *Cāin*, names so like *Cay* and *Can* as to suggest he was the high pontiff of Mayax and brother of *Aac* (Can II.), *Coh*, *Moo*, and *Nicte*. A *Cān-ok* is also mentioned as a son of Jared ("*Next Descended*"), and by Jude termed the "*Seventh from the First*," and probably a *seventh* high pontiff whose translation (*Genesis* v. 24) may have been that of apotheosis merely. The book of *Enoch*, or *Hanoch*, which is spoken of by Zohar as "an independent Hebrew production handed down from generation to generation," a MS. copy of which was rescued from oblivion and brought from Abyssinia in 1773, is little known owing to its supposed apocalyptic character. However, McClintock assumes it to be the identical book quoted by Jude ("Bib. Theolog. and Eccles. Cy.," vol. iii. p. 226), and declares that it "*exhibits a great advance of thought within the limits of revelation in each of the great divisions of knowledge*" (p. 227). Among other things it teaches the spirits of the wicked will be taken from *sheol* and consigned to a place of greater discomfort if not fitted for better things. Compare this with the *happy hunting-grounds* of the nomad (THERAPEUTIC GAZETTE, April, 1887, p. 231). Le Plongeon sees in the book a key to the ancient *Mysteries*, and remarks the similarity of its utterances to those of the *Popol-Vuh*, the sacred book of the *Quiches*. (Appendix N.)

|| The mastodon in Egypt became the bull *Apis*, in consequence of the latter being the largest animal of its class (*Mammalia*) known to the country. In India it became the elephant, the deity of wisdom (*Ganesha*), whose body is painted *red* or *copper color*. The *Mystai* were taught as the Brahmins are taught to-day, that this emblem, whether a *red* mastodon, *red* elephant, or *red* bull, should be regarded as an *emblem of the soul*, as *embodying power and greatness*.

Strange to say, *Adām* has the significance of *red* or *first red ruler*; *red* is the color of the American aborigine, and *red* was a symbol of nobility or race, and divine descent among the Egyptians. However, on the façade of the *Kuna*, or "Temple of Divine Intelligence," in Chichen-Itza is seen a tableau of adoration of the mastodon, over the trunk and between the eyes of which is a human face surmounted by the royal crown. The corona of the upper cornice is the emblem of the *serpent*, the token of the royal *Cans*; that of the lower is formed

the serpent,* the parrot, the palm,† and even apotheosized members of the human family, such were merely tributes to learning, and susceptible, among the higher *Mystai* or initiated, of esoteric explanation whereby the figures were resolved into symbols of the power of Nature, each within its own kingdom or class, and reconciled to the monotheism expressed by *The Supreme Intelligence*. Indeed, idolatry, like the manifestations of some forms of Christianity, developed from the ignorance and debasement of the masses proportionately with the decline of education and art, and the subversion of the lofty aims inculcated by the *Mysteries* to the debauchery of politics and sensuality. Maya monotheism begat polytheism by esoterically ascribing a triune existence to the *Supreme*,‡—the “*Creator*,” the “*Engenderer*,” and the “*Giver of Being*.” In a less advanced *Degree* of the *Mysteries*, the *Trinity* was pictured as a *Quinquenate*,§ still lower a *Septenate*,|| and in the first or lowest of all as a *Duodenate*,¶ whence the mystic power ascribed to the figures 3, 5, and 7. From the latter the vulgar evolved deities at will (aided by the political machinations of individuals), having no conception of the true meaning of the *Supreme Deity*, or of the figures that to the initiated conveyed evidences of his universality. A study of the polytheism of Egypt, Chaldea, India, and China evidences this; moreover, it is well understood on both sides of the Atlantic that an unknown but mystical significance has ever been ascribed to these numbers, and that by the Brahmins, Buddhists, Guebres, Mahatmas, and “*Adepts*” they are held to be potentially, if not Divinely, endowed, or, as Pythagoras puts it, “*The vehicle of life containing both soul and body*.”**

From Chichen-Itza Maya civilization extended its influence to the farthest parts of the globe, exercising a controlling power

among heterogeneous nations. History, art, philosophy, medicine, and the sciences in general were taught as the *Mysteries* gained ground, and everywhere the country whence the latter originated was regarded with veneration and respect. To-day, also, we encounter the word *Maya* in many regions, often most remote one from another,—in Europe, Africa, Asia, as well as the two Americas,—and always with the attached meaning of *original* or primitive power and wisdom; and wherever found, are also discovered traces of the language, customs, and religion of ancient Mayax, and its cosmogonical and historical traditions embodied in sacred writings and regarded as the history of mankind.†† By comparing the hieratic alphabets of Chaldea and Egypt with that of Mayax, the proposition that the former are indebted for their origin to the latter becomes something more than a mere surmise: the relationship is unmistakable. The radical MÂ, or “*first*,” the equivalent of our letter *M*, in all three is the symbol of the universe. MÂ-YÂ means simply the “*first derived*” or “*first out of the water*,”—*terra firma*; MÂM stands for “*ancestor*”; AH-ÇAMÂ or AH-DAMÂ for “*first of earth*” or *royal first*, a title given to but one of the *Cans* of Mâyax, while the others are designated as AHAU-MÂ, “*royally descended*.” Again, we find a brotherhood in India who from time immemorial have borne the name of MÂHÂ-ATMA, or the “*Soul of Souls*,” which exactly expresses their religious claims; and LA-MÂ, or “*that which has existed from the first*” (eternal truth), is the title of the Thibetan form of Buddhism. LÂB-MÂC, the “*Venerable*,” is identical with the *Râb-Mâg* of the Chaldeans, and is the designation of a high priest or pontiff; and MÂ-GI or MÂ-YI was applied to those possessed of the Maya knowledge (the *Mysteries*), and, like the title of *Doctor* to-day, obtained among charlatans as well as the learned. From the writings of Daniel we gather the *Mâgi* or *Mâyi* of his day were *strangers possessed of special learning and speaking an unknown tongue*,‡‡ and that they were a powerful society, esoteric and quasi-religious in character, who passed their time in meditating upon questions of philosophy and science, or in practising divination, astrology, therapeutics, and psychomancy. In the last, however, they were surpassed by the “*Son of David*” and by his companions, who, being of the blood royal, presumably had attained the highest rank in the Hebrew *Mys-*

of characters that read *Ah-âm*,—the “*first*,” or “*he of the throne*.”

** In the THERAPEUTIC GAZETTE for May last (p. 301) I commented upon the fact that *Shams* and *shamman* lodges are the repositories of the facts, traditions, and other knowledge of Primitivism, under the absurd title (as rendered) of “*medicine*.” See also U. S. History as to the sacred lodges of the Natchez tribe in connection with an intended (universal) massacre of the whites!

†† Appendix M.

‡‡ Books of *Daniel*.

teries, and, moreover, by order of Nebuchadnezzar, had also acquired all the "wisdom" of the sacred colleges of Chaldea. In the short space of three years Daniel had risen to Chief Pontiff or "Venerable" of the kingdom, and undoubtedly it was his better knowledge of the means of procuring *ecstasia** and the clairvoyant state, that procured him honors and caused him at the same time to decline the luxuries ("delicacies") of the king's table. As the higher and more complete wisdom of the *Mysteries* inculcated *caste*, we can imagine the Māyi, foreigners from India,† probably, who had settled in Babylon for "profit and gain," were not the most exalted of the sacred ranks, for it is rare indeed that any considerable number of emigrants represent the best learning of the country of their birth.

The totem of the primitive kingdom of Mayax was a *serpent*, typical of water or the sea,‡ bent to represent the coast of Yucatan, while the peninsula itself was often typified as a *garden*. But the insignia of the *Empire* of Mayax, which extended from the isthmus of Darien to that of Tehuantepec, was sometimes a tree§ with its roots in the continent of South America, the peninsula of Mayax being the chief branch, and sometimes (more frequently) a *serpent with an inflated breast*, the outlines of which exactly recalled the geographical contour of the country.|| This serpent was also employed as the emblem of royalty and apotheosized royalty as expressing wisdom second only to that of the Divine Intelligence, and as such it appears as a head ornament in sculptures and gravures. Also, this latter reptile is, manifestly, the "asp" of the Nile region, where it is frequently depicted wearing the crown of Lower Egypt, said crown being but the Maya royal appendage reversed,—the front looking backward; this reversal, perhaps as a mark of respect, and intended to inculcate the principle yet obtaining among the people of Yucatan, that as the child is *less*, it should always appear *inferior*, and in *homage* to the parent,—i.e., stand behind him.¶ Nine thousand and more years subsequent to the submergence of Atlan that interrupted communication between the two hemispheres

for a hundred and half a score of centuries, we find this "asp"—so called, though with but trifling resemblance to the *naji haji*, or cobra—as the emblem of the royalty and wisdom of Egypt, and as such adored under the title of *Mā-ti* or *Uā-ti*, typical of *Amenti*, or the "Land of the West," to which the souls of the departed were expected to *wing* their way.** The "ark," too, is observed as part of the properties of the early Egyptian and Chaldean *Mysteries*, whence it obtained place in the religious worship of the Hebrews; it was generally in the form of a *caïque*, or boat, and in each case was cherished within the "holy of holies" as a "covenant" or *bond*, the real significance of which was its former use as a means of communication between the lands of the West and those of the East, such as was possible before the destruction of the "Lost Continent."

Regarding the *tree* emblem, we know that grove or tree worship is yet extant in many parts of our globe, and in Yucatan it is still the custom to surround houses of worship with the emblem of the Maya Empire, the *cieba* tree. In this is also found a key to the grove *Mysteries* of the Hellenic Peninsula and Greek Mesopotamia, the Druidical rites of Œsus, the oaks sacred to the royal Baal of the Phœnicians or Assyrians, the ash venerated by the Scandinavians, the tamarind adored in Egypt, the palms of Delos and Ceylon, and the significance of the banyan, or *Ficus Indicus*, in the Deccan; in each instance the tree selected being the most hardy and enduring of the region, and therefore typical of *strength*. Also, we obtain better understanding of the significance of the brazen serpent reared in the wilderness by Moses,†† who, as the putative child of Thonoria and grandson of a Rameses, would obtain early initiation into the *Mysteries*, the influences of which are everywhere manifest throughout his career. Presumably, in Arabia whence he fled soon after discovering his ignoble origin, was obtained further wisdom, for the *Mysteries* of that country were already famed

* THERAPEUTIC GAZETTE, April, 1887, p. 235.

† Valmiki, in the Sanskrit poem "Ramāyana," tells us that colonists from Mayax in very remote ages took possession and settled a portion of the Indo-Chinese peninsula now known as the Deccan.

¶ Ibid., p. 118.

** Here we have, perhaps, a clew to the theory of Angels, though in the main these spiritual beings seem to be derived from the *messengers* employed as go-betweens by the mythological deities of old: these messengers were in no sense themselves deities. (See Prof. W. Robertson Smith's "Doctrine of the Angels," *Pop. Science Mo. Supplement*, No. 61, p. 514.)

†† *Mā-shā* (Moses) in the Maya tongue means "From the *First Taken*,"—i.e., drawn out of the water. It bears no evidence of being an original Hebrew word, and the history of the man is opposed to such supposition.

for their teachings in natural science; and here, undoubtedly, for a time he gave himself over to asceticism and meditation with a view of wiping away the "stain of blood" that was upon him, developing *ecstasia* more profound than that taught by the schools of Chemi, whereby were obtained visions like that of the "burning bush" described in Hebrew records.* Returning, he sought to relieve his people from degrading bondage, and with them found a government based upon the highest conceptions of the "*Supreme*" as taught in the sacred colleges, at the same time doing away with the esotericisms of the minor degrees and removing the debasing influence resulting from the teachings of apotheosis. The construction of the tabernacle with its appointments and "holy of holies;" the "ark of the covenant" with its deep signification; the limiting of high advancement to the members of his own tribe (subsequently a privilege that accrued to royal blood), and to individuals physically and mentally perfect (*Levit.* xxi. 17); the typifying the land to be seized upon and occupied, as that of *Can* (Canaan); the attempts to lift his followers to a higher plane morally and intellectually while inculcating implicit obedience,—whence the forty years spent in the "desert"; the laying of tithes or taxes; his individual knowledge of natural laws and of therapeutical, pharmaceutical, chemical, hygienical, and astronomical science; all exhibit the training of Heliopolis and Memphis, and stamp him as not only one of the most advanced of the "*Initiated*," but scientifically and politically one of the greatest men developed by any age or era.† Little wonder his name is revered by existing generations, or that at the court of Pharaoh he won the victory over the Magi who by their very caste and calling were limited in knowledge!

The sciences and arts that had the seal put upon their sepulchre in the murder of the beautiful and gifted Hypatia of Alexandria, daughter of Theon the mathematician, by the rabble following of Bishop Cyril, were already upon the wane in the time of the great "law-

giver;" already the hermit colleges of Arabia ranked higher than the temples of the Nile Valley. The unity of the *Mysteries* had been weakened by secessions and subdivisions that, while lessening their value, opened the way for political trickery and individual ambitions, further fostered by the spread of the pernicious doctrine of apotheosis. The ranks of the *Mystai* received accessions from those who sought the guise of knowledge rather than true learning, and power rather than intellectual development, whereby the miraculous superseded the philosophic. The higher degrees were first neglected, then their divisions broken down by prostitution to the will of a political majority, and a few centuries later they had ceased to exist save in name, or had disappeared in the unknown regions of the farther Orient,—beyond the Caspian and the Persian Gulf,—there to linger and languish for lack of intellectual support and nourishment until the present hour. Brahminism, Buddhism, and Confucianism are the imperfect survivals, the two former retaining the fragments of an obscure psychism, the latter inculcating the subservience of all things to education and intellect. With a spasmodic uplifting and revival, the greater *Degrees* were partially and imperfectly restored to the Chemitic colleges, passed over into Greece and thence to Rome, only to return to Egypt in still further debauched condition, and to again retire to the fastnesses of Arabia, whence fragmentary portions came to us in later years by way of the Levant and Iberian Peninsula. The Greek and Roman Emperors, influenced on the one hand by the Christian Church,—that by the means taken to insure the spread of its doctrines received constant accessions from the ranks of the illiterate and vulgar,—on the other fearing the influence of the learned and wise, persecuted the latter even to death. For centuries knowledge was criminal; the exercise of reason and thought, treason and heresy;‡ and thus the last vestiges of the grandeur of the remaining *Mysteries* were crushed, and their esotericisms, lost to all true meaning, came to be embodied as part of religious creeds the better to satisfy the clamors of a superstitious populace;§ not the least of which in political bearing and import was the anthropomorphosis of *Isis*, or

* *Exodus*, iii. chap. It was long taught, as is yet the case among *Derwishes*, that to pass into a condition of *ecstasy* is a foretaste of absorption in or *union with* the Supreme. No religion is without ecstatic relations; to this hour we see it in orthodox "*revivals*" so called, in "*spirit circles*," and all forms of devoteism.

† *Ibid.*, chap. xxv. to xl.; xxx. 34–37; *Levit.* x. 9–10; *Ibid.*, xi. to xxi.; *Deut.* iv.; *Ibid.*, xiv.; *Exodus* xxii. 20; *et al.*

§ "The reign of Constantine marks the epoch of the transformation of Christianity from a religion into a political system," etc. *Ibid.*, p. 52.

Mau (the apotheotized *Moo*), as *Maria* or *Mary*, the *Mother of God*.*

In Mayax, Egypt, Chaldea, India, and all ancient countries with pretensions to civilization, the acquisition of knowledge was made illicit save to those of the *Mysteries*, and thus, directly and indirectly, was fostered the principle of *caste*. Something of the same lingers even yet, and may be observed among primitive nomads, though they have advanced politically sufficient to recognize the value of bribes in removing otherwise insurmountable difficulties.† Garcilasso de la Vega informs us this was the case among the Shyris and Quichuas,—a statement that is corroborated by Bishop Landa as to the tribes of Mexico and Central America. While the *Mysteries*, in the main, were the privilege of birth and class, it was also possible, under conditions, for those of lower castes (females as well as males) to enter certain lesser or modified degrees, whence they might be advanced, if capable, by taking upon themselves the vows of sacerdotalism; but such candidates must needs exhibit special aptitude for the offices prescribed, and were tested in various ways by ordeals,‡ examinations, and appalling rites. Thus the real or active priesthood, more rapidly recruited, in time became the more influential and powerful factor, especially as standing in the gap between education and debased intelligence. Little wonder that the *Mysteries* degenerated and became prostituted to political power, for whoever runs may read that, in all ages and climes, among nations of high civilization as well as those steeped in the dregs of abject barbarism, the priestly class have ever arrogated to them-

selves special privileges because of their supposed familiarity with the Higher Presence,§ and also have jealously guarded their scientific and intellectual treasures from the vulgar by throwing about them the veil of superstition and mystery. In both the higher and lower *Mysteries* all discoveries, real or feigned, and all manifestations of thought and intelligence, were hidden beneath a cover of symbols the secret or esoteric significance of which could be penetrated only by the initiated,|| while the common people were given such exoteric explanations as were conveniently plausible. This principle is yet adhered to by Buddhists, Brahmins, and Adepts; by the Christian Jesuits who profess to be the repositories of all knowledge, theological, philosophical, and therapeutical,—though in many ways inferior to some of their heathen prototypes; and by various secret organizations, including the different branches of Masonry, which itself is, in a sense, a survival of the *Mystikos Sekos*. With all, the secrecy for centuries upheld and still observed, is justly deemed the guarantee of honor, profit, and power.

It has before been remarked that the Sacred College embraced various orders and classes as well as degrees. Some of these led directly to the *Mâc*, or *Ephori*, as the Greeks were wont to denominate the highest perfection, which was the last step before reaching the degree that should entitle the aspirant to privilege of direct communication with the *Supreme*.¶ others were self-limited, having been instituted with special designs or purposes. There were others also not of the *Mysteries*, but *Mystical*; but these were of comparatively modern origin, and in the nature of extraneous religious worship, political and social organizations, or of the class of the *Saturnalia*.**

The first, taught the various branches of art, science, and philosophy, relatively and progressively, as a means of greater esoteric

* The cross from remote ages was an emblem of the *Mysteries*. The ancient astronomers of Mayax observed that at a certain period of the year, just at a time when their country otherwise would suffer from drouth, the rainy season was heralded by the *Southern Cross* appearing perpendicular to the southern horizon. This is our month of May, which owes its name to MAYA "the good dame," the "mother of gods." The cross was everywhere associated with water or rain, and the emblem of the goddess thereof (Maya). This is why the Romish Church celebrates the feast of the *Exaltation of the Holy Cross* on the third day of the fifth month, which it has consecrated to the "Mother of God," "our Good Lady," the virgin *Mâ-R-îâ*, or the goddess *Isis*, anthropomorphosed by Bishop Cyril, of Alexandria. Isis was the sister of Osiris, therefore the Mayax *Moo* (also called Maya), being a dialectical mode of expressing the Maya word *icin* ("the sister"). She is also termed *Mau*, and one of her titles, like *Moo*, was "royal wife and sister." (Appendix K.)

† THERAPEUTIC GAZETTE, April, 1887, p. 235.

§ Ibid., pp. 233, 234.

|| Herein consists the mystery of the Bible and other ancient writings, and that is expressed by scholars under the name of "Orientalisms." The esotericisms of the *Mysteries* indelibly stamped themselves upon the languages of the East, and likewise are found exhibited in the speech of various nomadic races, including the aboriginal inhabitants of America.

¶ *Hâc-mâc* or *Lab-mâc*, "The True," the "Very One," was the title of the high pontiffs of Quiche and Mayax, and the highest degree attainable in the ancient Central American *Mysteries*.

** Compare with the plan of the Church of Rome, from the Pope down to the lowest priest or acolyte!

understanding, and of nearer approach to the Supreme, Mysterious, and Occult—to Deity; in the second the knowledge acquired in the first was given the more practical bent necessary to satisfy the demands of utility.

In Mayax as well as the East, those who attained the "higher perfections" were to greater or less extent invested with supernal attributes in the eyes of their inferiors and of the vulgar, and there is little doubt they were more familiar with the secrets of Nature as manifested by the laws of psychism than any of the present age; perhaps also they may have had a more definite and thorough conception of Deity itself. Abdemonus the Tyrian, grand vizier to Hiram, would seem to have been one of these fortunate individuals, since the traditions of the Orient picture him as a *genie* in human form whose wisdom exceeded that of Solomon.

That the pre-historic as well as historic races of these ancient civilizations were not steeped in degraded bigotry, barbarism, and superstition; that their knowledge was not limited by a low and debased form of intellectuality; is made manifest by their records and by existing monuments. The evidences at command point out they were our superiors in art, architecture, mathematics, astronomy, and, to some extent, mechanics. Scarce anything of the present will endure like the mural paintings of Uxmal and Chichen-Itza, the sculptures of Thebes and Memphis, the rock decorations of Elephantis, or the walls of old Jerusalem; in China from time immemorial the mathematics so difficult to Latin and Anglo-Saxon races are the pastime of infancy and childhood; the pyramids and clepsydras of Yucatan and the Nile, and massive stone sextants, quadrants, and dials of India bear witness of exhaustive astronomical science, and we now know the form of the earth and its relations to the solar system had been defined and measured, and observations regarding eclipses, equinoxes, solstices, conjunctions of planets, and occultation of stars, recorded that but recently were deemed new; and when a French engineer caused to be engraved upon its pedestal the ponderous machinery invented to lift the Luxor obelisk to its place, a similar feat of engineering had been performed for its fellow in St. Petersburg and at the hands of a Trans-Caspian mujik with the simplest of appliances aided only by the traditions of his race! The *Troano* MS. would take high rank as a geological work in any age; the *Popol-Vuh* will compare favorably with any literature of its class, even

the Apocalypse; and the fragmentary records of Assyria and Chaldea engrafted upon the Hebrew yet preserve their freshness and interest. Neither are there valid reasons for imagining the various branches that go to make up the science of medicine were all in the degraded and debased condition described by Hippocrates, whom it is the fashion to style the *Father of Medicine*, but with equal propriety might be termed the *Prince of Munchausens*, for it is now known the writings that bear his name are chiefly factitious, and not the product of any one pen or age. Moreover, the ancient authors who could impart the desired information, by the oaths exacted in the *Mysteries*, were forbidden to perpetuate their knowledge save in esoteric form—in parables.*

The discoveries in Yucatan and Central America are too recent to afford definite or precise knowledge regarding the therapeutics of the ancient races, save in their psychophysical relations. With anatomy the edu-

* It is claimed by the Jews and supported by their traditions, that the founder of Christianity received his education in Egypt, whence he was carried to escape the jealousy of Herod, and there became familiar with the Mysteries and their doctrines. This would seem to have at least the basis of plausibility in that he taught by means of parables and enigmas, which was the language and method of the Colleges, and inculcated in his followers the communism and simplicity that obtained with the *Mystai* among themselves. (The primitive churches were communal, though not to the degree the term implies in our day.) That he was familiar with psychic influences as manifested by the phenomena popularly denominated *animal magnetism*, is apparent from the remark to which utterance was given at the time the woman "with an issue" sought to be healed by touching the "hem of his garment" (*Luke* viii. 46): "*Some one did touch me, for I perceived power had gone forth from me*" (also *Mark* v. 28-34). Again, his last words upon the cross, that have ever been a matter of puzzle and dispute to philologists (*Matt.* xxvii. 46), prove to be *pure Maya* with practically the same significance as given by John (xix. 30), or "*Finished; finished; and darkness is upon me*," or, "*will cover my face*." We know the "Beloved Disciple" was of higher rank educationally than his collaborators, and hence would be more apt to understand the true meaning of the Mystic sentence, "*Eli, Eli; lama sabach thani*," that Matthew and Mark surmise to be an adjuration to *Elohim* (God); or more likely the sentence, "My God, my God, why hast thou forsaken me?" is an unauthorized interpolation, since *Eli* is the Græcized *Eloi* of the Armenian tongue. That foreign words survived in the *Mysteries* and were employed for certain esoteric purposes we have evidence in the *Kon-x Om Pan-x* that wound up the *Autopsia* and that has no meaning in Greek: also *Cansha Om Pansha* employed by the Brahmins to-day in the same sense as the Romish "*Ite missa est*," and to dismiss their assemblages. Both are apparently derived from the Maya vocables *Con-ex Omon Pan-ex*,—"Go forth, strangers; disperse."

cated orders and the priesthood must needs have been somewhat familiar, for embalming, both partial and complete, was practised. In the sculptures that detail the life of Prince Coh, the final picture of the tragedy is the preparation of his body for the funeral pyre; and by a transverse incision in the abdomen, directly beneath the xiphoid cartilage, had been removed the heart and viscera that were to be preserved, and that are exhibited in the hands of his relatives. Embalment, here as in Egypt, presupposes extensive familiarity not only with the internal arrangements of the human economy, but also with aromatics, astringents, and antiseptics, and perhaps acids and chemicals; and a race accustomed to preparing and mixing colors for the purpose of adorning the walls of their palaces and temples, would scarce be so ignorant of the true values of articles of the mineral and vegetable kingdoms as to ascribe to them supernatural and diabolical virtues. Sculptures and pottery relating to the therapeutics of childbirth are quite common. The National Museum of Mexico is rich in these, and they exhibit a minuteness and fidelity of details that evidence extensive familiarity with the parts involved and their physiology; also with various abnormalities and presentations; with *massage* for correcting the position of the infant; with turning; manual expression, and mechanical aids and appliances for the removal of both child and placenta. In one instance the condition of a lady is expressed by a protuberant abdomen upon which is pictured the size and development of the foetus, indicating that at the time of death she was some four months advanced in pregnancy, and the faithful delineation of the uterus and its contents would serve fairly well to illustrate the teachings of this period of gestation in our own day.

In the records of ancient Egypt we have even broader views of medical science. Glimpses are had of pharmacal and chemical knowledge; of shops for the compounding and sale of cosmetics, perfumes, "sweet unguents," and drugs; and we also are treated to pictures of gynecal, obstetrical, and surgical operations, including amputation, resection, and *trephining*. Syncellus informs us of the existence of a *Pharmacopeæ Chemi*, adding that ætites were employed for ascites and to procure abortion, *carbonate of lead* and *sulphate of copper* for soothing and astringent ointments respectively, that a solvent was known for renal and vesical calculi, and the crises and courses of fevers understood; also

we surmise that the *nepenthe* of Homer given by the Theban queen to Helen of Troy to soothe her sorrows was a narcotic draught; and the same poet's description of the *Lolophagi* presupposes too great a familiarity and indulgence in opium or hashish.

There were also lower or subjective orders of priests and *Mystai*, by the Greeks termed *Pastophori*, whose duty it was to minister therapeutically to the needs of the common people and the military, and in return therefor derived an income from the public treasury. These were individuals of comparatively low origin, with mere smattering of education, who employed charms, amulets, and other psychic measures compatible with and attractive to the tastes of their beneficiaries. Moreover, they were obliged to confine themselves, each to a special form or class of diseases, for a stated number of days implicitly following the routine* prescribed by the Sacred College or the chief of their order, ere innovations could be made. Under such circumstances we are not surprised to learn that progress was slow among this class of practitioners, or that officers of rank frequently themselves sought to alleviate the sufferings of those under their command.

But, because the masses were wedded to ignorance and superstition carefully fostered by the dominant classes, we have no precedent for believing the *Initiated* were steeped to the lips in gross fetichism, or that therapeutics, as commonly asserted, were "no more than absurd worships rendered different divinities." Are the masses representatives of the education and refinement of our modern civilization, or are they free from charlatanism, superstition, and miracle-worship? Was the symbol of *Thoth* or *Osiris* worn suspended from the neck more absurd than texts from *Scripture* now advocated and employed by the exponents of "The Divine Art of Christian Healing,"† or the bits of "blessed Eucharist," medals of Virgins or Saints, or—better yet—the "black cat's skin-poultice" ordered by a regular physician at the request of the wife of a United States

* The Mysteries rigidly enforced their rules. We see this in the Hebrew *Law*, and again in a study of the public art of Egypt, where everything was built and chiselled on precise scales, and by the same esoteric rules and lines. In private art, however, we find notable exceptions, and evidences of the discard of canonic and mathematic idealization in the interest of truth: for instance, the fragment in the museum at Boulac that has been dubbed "The Schoolmaster,"—"an undeniable portrait." (Reber's "Art," p. 41.)

† *Century*, July, 1887.

Senator to relieve *globus hystericus*? Does the bulk of the clergy of the nineteenth century represent the advanced thought and education of their calling, or do the multitude of practitioners evince skill in pathology, physiology, or therapeutics? The learned of Egypt did not often exercise their skill save among their own degree and caste; and with such a civilization, even though knowledge was esoteric and privileged, there must needs have been considerable progress in medicine and therapeutics, since both are, in a sense, contemporary with man's reclamation. The pity is that we cannot penetrate the secrets of the past to determine the heights to which they had risen. That medicine was a long way removed from superstition and occultation is evidenced by the fact that seven books devoted to this subject were part of the properties of the temples, six of which, including a treatise upon the *Eye*, were ascribed to Thoth, the preceptor of Isis, the other, an exhaustive work on Anatomy, from the pen of Athothems II.; and these volumes were so complete that no one man within the limits of public usefulness could master them all, for which reason the *Pastophori* were restricted to special walks of professional life.* Again, it is recorded that one of the Ptolemies devoted his leisure to comparative anatomy and physiology, performing dissections under his own hand; and at a later period a school of practical anatomy was founded at Alexandria. Wunderbar, after carefully weighing all the evidences, declares the higher *Mystai* were physicians of "rich cultivation and attainments;" and that this was the impression abroad, appears from the request of Cyrus that an Egyptian *Oculist* be sent to the court of Persia. At this time it also was the custom, in all parts of the world, in all matters of Life and Philosophy, to seek counsel of wise men who were chance visitors from other countries.

Among the early Hindus six books† were

cherished corresponding to those of Thoth in Egypt, and a seventh, *Bajikarana*, of later date, and sometimes deemed spurious or apocryphal to the *Mysteries*. These constitute the *Agur-Veda*, which Sir William Jones, after cursory examination, further hampered by lack of practical familiarity with Sanskrit, pronounced mere empirical histories of diseases and their remedies. But this criticism may or may not be just, since the key to their esotericisms is probably lost; and to-day it is practically impossible, for the same reason, to obtain parallel interpretations of the Hebrew and Greek Scriptures. The *Shastra* teaches each form of life contains within itself certain elements, the relations of which one to another cannot be disturbed with impunity, and whence the ultimate conclusion that all diseases are the manifestations of increase or diminution of such elements, whereby is established the preponderance of one or more to the exclusion of others. Who will definitely criticise such physiology, or decide exactly how far it is right or wrong?

The native therapeutists to-day, especially among the lower *castes*, are represented by mountebanks,—dealers in amulets, charms, and sham esotericisms. It is not at all strange, however, considering the vicissitudes by war, rapine, bloodshed, and famine, that in rapid succession have overtaken the Indo-Chinese peninsula, that the education of the *Mysteries* has practically vanished, the little remaining being a literature that, while it commands our admiration, conveys little of its true meanings; or that the inhabitants have reverted to a primitive and demoniacal system of philosophy, and the Fakir (*Pastophori*), hurried on by the greed that is inherent to all the human family, has fallen to the low estate of the original *Sham*.

In all matters that are not distinct historic records we are accustomed to accept the prejudices of the Greeks and Hebrews, and deny the peoples whose civilizations were a reproach to these two nations the exercise of the commonest intelligence. Neither the Hellenes nor the Jews ever builded so massively or grandly as those of Petra, Assyria, Persia, Arabia, Hyrcania, etc., that—following example—we are wont to term "*Barbarians*." Herodotus is cited as authority that Chaldea and Persia were destitute of therapeutic talent because it was the custom to expose the "ill and afflicted upon the market-places" in the hope some one might take pity thereupon, and because on certain historical occasions physicians were summoned

* Says Surgeon-General Charles A. Gordon of the *Horse Guards*, who has paid considerable attention to anthropological medicine, "The art of healing in Egypt had evidently attained a recognized position prior to 2717 B.C.; and in the '*Papyrus Ebers*' there is evidence that knowledge of the treatment of disease was more advanced than in the time of Galen, or the second century of our era!"

† The "*Salya*" and "*Salakya*" were devoted to traumatic and organic surgery; the "*Kaya-Chiketsa*," to practical medicine and therapeutics; "*Bhutaridaya*," to mental phenomena and diseases; "*Kaumara-Bhritiya*," to diseases of women and children; "*Rosayana*," to chemistry; "*Bajikarana*," to sexuality and the increase of the human race.

from the banks of the Nile or the hills of Attica. But in either case the record is imperfect, and, moreover, it is doubtful if its author ever intended such interpretation should be placed upon it. The exposure of the pauper ill to public gaze on the market and in the vicinity of the caravansaries, for the selfsame reason, is yet a custom of the Orient.* It is in the hope they may attract the attention of some learned and travelled wise man, or *derwish*, who will bestow his services gratuitously; and a foreign *Hadji* is always in greater repute, no matter how apparent his imposture, than the skilled wisdom of local talent. We know there were Hebrews who were *Ephori* in Babylon, the Ecbatanas, Persepolis, and Nineveh; likewise Magi, who were capable of ministering to those of their own caste. Xenophon† declares that Cyrus "got the best physicians about him," and "whatever instruments and medicines were needed," and that he was "grateful" for their services, and "spared no expense" in their education; and it is not at all probable the whole empire, or even its army, was at the mercy of foreign hirelings. Finally, the summoning of experts from abroad, without more specific evidence, is entitled to no more consideration or comment than accrues to the same in the present decade.

The Children of Israel, deriving their civilization from the banks of the Nile, closely followed the teachings and precepts of the Chemitic colleges. The masses of Egypt, crushed by the weight of ignorance and misery, then as now passed their lives in filth and brutality. Moses, from the very outset of his political career, however, sought to lift *all* his countrymen to a higher level of intelligence and morals, and unite by the broad bond of community of purpose and thought. With this view the lesser *Mysteries* were thrown open and their esotericisms made public; woman was lifted to a higher plane socially than was known in Egypt, save among the noble classes; virtue, temperance, thrift, chastity, cleanliness, and obedience were inculcated, along with statutes manifestly derived from close contemplation and study of natural laws and objects, such as were known only to those familiar with the inner courts of Hieropolis and Memphis; and all were made imperative as being specific acts, released from the veil by command of the Su-

preme Intelligence, who thus sought to draw a "favored race" nearer to Him.

It must necessarily be granted that the great "*law-giver*" who had penetrated the secrets of nature as taught by the highest *Mysteries*, and who was deeply versed in the laws of hygiene and prophylaxis,‡ could not have been wholly ignorant of therapeutics, for among the rudest peoples, if at all progressive, remedies selected at random through some supposed esoteric or spiritual influence, by empirical application must lead, ultimately, to increased and specific knowledge. Prejudiced by the precarious and uncertain information afforded by history that at its best is but skeletal, we ignore the deeper and relative meanings of the *Talmud*, *Mishna*, and *Scriptures*. Turn to the former, and in the treatise termed *Chulin* discover a detailed description of the pathological conditions indicative of disease in animals designed as food, including *trichinosis*. In *Leviticus* and *Deuteronomy* note the directions for preserving individual and public health; the selection of portions of creatures for sacrifice, and rejection of those organs of the economy whose functions are the removal of impurities or excretion; the disposal of filth, that it may contaminate neither air nor water; the disposal of the dead; disinfection and purification of clothing and dwellings and the laws of quarantine;—all of which indicate deep physiological and pathological knowledge. Will any one presume to say that the human race—male and female—would not be materially improved both as to health and morals if the Mosaic law was rigidly enforced to-day?

Moses, we read, prepared ointment according to the "apothecaries' art," and apparently he possessed considerable familiarity with chemistry and metallurgy.§ Solomon speaks of the "powders of the merchant,"|| proving that a distinct trade was carried on in pharmaceutical products; and in one instance we find a prescription in due form.¶ Again, Moses, Elisha, Daniel, Balaam, and others give evidence of skill in *ecstasia*, *psychomancy*, *clairvoyance*, etc., and the first three manifestly were adepts in the art of appealing to the nerve-centres through the medium of the senses. Solomon was undoubtedly familiar with zoological and anatomical science, skilled

† Institutes of Cyrus, book viii.

in the arts, and conversant with the laws of heredity, besides possessing knowledge of therapy. Josephus mentions his ability to "expel sicknesses."* His reputation for the production of psychophysical phenomena, and as one of the highest of the *Mystai*, is the theme of Eastern story; and from all accounts he should have had some slight knowledge regarding *women*. And we read that King Asa, when his disease was great, "sought not the Lord,"—i.e., the privileges of the higher Mysteries to which his rank entitled him,—“but the physicians,” or Jewish *Pastophori*.

The *Talmud* affords glimpses of a somewhat extensive pharmacopœia, including, as it does, decoctions, draughts, infusions, wines, vinegars, syrups, oxymels, essences, mixtures, liniments, cataplasms, blisters, ointments, electuaries, clysters, plasters, powders; also cathartics, emetics, tonics, sudorifics, expectorants, pyretics, tonics, abortives, soporifics, hæmostatics, astringents, poultices, and depilatories. The following substances receive individual mention in connection therewith: water, wine, beer, vinegar, honey, whey, milk; oils of opobalsamum, myrrh, rose, palm-christi, cotton-seed, walnut, sesamum, colocynth, fish; figs, dates, melons, apples, pomegranates, pistachio-nuts, almonds, pitch (bitumen), also all grains; leeks, onions, garlic, beets, mustard, pepper, coriander-seed, ginger, cummin, beside various herbs steeped in oil and wine; eggs, salt, suet, wax, fish-gall, ox-gall, ashes, cow-dung, pigeon-dung, bats' blood and droppings, and the droppings of sheep and fowls, *album græcum*, urine, “fasting-saliva;” calamus, aloes, myrrh, frankincense, myrtle, endive, mint, anise, fennel, cotton-plant, lily-roots, madder, narcissus, wormwood, jessamine, laurel, clover root and tops, jujube, hyssop, thyme, fern, milk-thistle, broom, juniper, poppy, acacia, pine, lavender, rosemary, saffron, madragordia, cinnamon, canella, cassia, spikenard, styrax, mandrake, *mentha gentilis*, *alhenna*, *sampsuchum*, *curaca maralis*, *ladanum*, *galbanum*, *blatta byzantium*, *ammeisision*, pyrethrum, musk; ætites, mercury, soda, litharge, borax, alum, clay, iron, copper, lead, yellow arsenic, bitumen, and *theriaca*. Certainly no very disreputable showing.

Wunderbar enumerates from the *Mishna* and *Talmud* no less than fifty-six forms of surgical instruments and appliances, exclusive of the obstetric stool referred to in *Exod*.

* Ant. viii. 2.

i. 16, and again in 2 *Kings* xix. 3. But surgery ranked less high than medicine by reason of being deemed a *mechanical* accomplishment, and, as is yet the rule in the East, united with it the profession of barber, and in Egypt, oftentimes, that of embalmer. The statement so frequently made that the ancients imagined the heart increased in size until the fifty-sixth year, and then slowly atrophied until death claimed its victim, must be taken cautiously. It was probably a figurative expression having reference to man's liberality, and not to a supposed anatomical feature, whatever may have been the construction placed upon it by the vulgar. The same is also true regarding a nerve extending from the ring finger to the heart.†

Medicine early declined among the sons of Jacob. It is doubtful if it ever reached higher perfection than at the time of Moses; certainly not after Solomon. From the reign of the “wise king” the decay of the race as a political factor has been steady. The heredity of nomadism has never been wiped out. While individually giving evidence of high intellectuality and capable of reaching any goal, the masses of the Hebrews, especially of the far East, are less civilized than at the time of the Exodus. Jewish physicians, however, among all nations, have ever taken high rank, and to-day it is rare to find one in the midst of civilization who is not an able physiologist, pathologist, and therapist, or who is not well informed in all collateral branches and sciences.

APPENDIX.

K.

Undoubtedly the story of Abel as it appears in *Genesis* was derived from the history of Osiris through Chaldaic sources, alterations having been made to preserve the mysticisms of the sacred colleges; for those acquainted with the truth as obtained through the *twelve* degrees would only give such exoteric explanations thereof as might suit their purpose or convenience. It is for this reason that so little is learned from ancient writings and authors: herein consists the mystery of the *Scriptures*; and this is why Herodotus, confessedly one of the *Initiated*, excuses himself for lack of explicitness; and Plutarch in his “*Osiride et Iside*” only purports to give such explanation as will satisfy certain of the inferior *Mystai*.

† This has been confused with the little finger by some authors, which had a specific office prescribed to it in the pouring out of libations. It was the *ring* finger of the *left* hand that was supposed to be *nearest the heart*, and it was for this reason the *third* finger of the *left* hand was chosen to carry the marriage circlet—a superstition that yet obtains as custom in our own day.

The Hebrew (non-scriptural) tradition is that Abel and Cain each had a twin-sister, and that Adam proposed to give the elder daughter to the younger son, and the younger daughter to the elder son, in marriage. This was every way agreeable to the first-mentioned couple, who had conceived a deep affection one for the other; but unfortunately the elder brother had fallen in love with his twin, she being the more beautiful of the sisters; hence the tragedy.

Osiris, who was the culture hero of Egypt, espoused his royal sister Isis or Mau, and fell a victim to the jealousy of his brother Set, or Typho. A similar tale is found in the Sanskrit "Ramayana," the victim being Bâli, his murderer Sougrivâ; and the recital is so nearly identical with that archived in the sculptures and paintings of Uxmal and Chichen-Itza, and recorded in the second part of the *Troano* MS., that it is more than probable it was imported from Yucatan direct, perhaps by the colonists who, as Valmiki (the author of the "Ramayana") tells us, settled in the Indio-Chinese peninsula (the Deccan) in remote ages, and who naturally would bring with them the language, customs, traditions, civilization, and folk-lore of their native land.

The Mayax history as it appears upon the walls of various cities of Central America, according to Le Plongeon, is substantially as follows: Cân (the *serpent*), the founder or restorer (*Ahdama*) of the ancient empire of Mayax, possessed three sons and three daughters, respectively named Cáy (*fish*), Aâc (*turtle*), Coh (*leopard*), Moo or Mau (*macaw*), and Nicté (*flower*). As was subsequently the case in Egypt, Ethiopia, Mesopotamia, and other countries, the law of the land demanded the youngest son should espouse the eldest daughter in order to insure legitimate and divine descent; so Moo became the wife of Coh, greatly to the satisfaction of both. Aâc, however, was deeply enamoured of Moo, and sought her hand in defiance of law and custom; moreover, he was deeply jealous of Coh, because of the latter's popularity, and fame as a warrior and huntsman.

With the death of Cân Ahdama, Uxmal, the "Land of the Sun," fell to Aâc, and Chichen-Itza, "Land of the Serpent," to Moo, who shared the sovereignty with Coh; Cáy being High Pontiff of Mayax was not eligible to the throne. Immediately Aâc began plotting to seize the whole kingdom; and finally, after an altercation with Coh, satiated his jealousy by three spear-thrusts in the back of the latter. The country was now thrown into all the horrors of civil war, though Aâc, who was more of a diplomat than a warrior, soon made proposals for the hand of Moo. This tableau represents Moo seated in her house in the midst of a garden, at her feet a basket of oranges ("golden apples"), her hand stretched forth indignantly, spurning the gift, and warning away the supplicating messenger; Aâc is seen on a lower plane making obeisance, while overhead his royal totem, a *serpent*, ogles the macaw perched in the tree above Moo.

Here we have the explanation of the "Temptation," the "serpent," the "apple," and the cause of the fratricidal strife. A basket of oranges is to-day the means employed by the Mayas for conveying an offer of marriage; the serpent was the royal insignia of Aâc as a sovereign, though his individual totem was a turtle; and the whole, whether found in *Genesis*, the "Ramayana," in the *papyri* of Egypt, or in the legend of Kronos of Atlantis, is merely the feud of the children of Cân I. that, passing from mouth to mouth, generation to generation, and country to country, has in some instances suffered slight

disfigurement, probably at the hands of those who were not accustomed to hold woman in the same high veneration that pertained to the sex in Mayax. In Yucatan only is found the narrative as part of the history of a nation; here alone have been discovered the portraits of the actors, the ornaments and weapons they wore, their tombs, and the embalmed and cremated remains of their mortality. Who can doubt the identity of Cân and Zoç with the Chaldeo-Hebrew Adam and Eve, or Chemitic Seb and Nut; or of Cain, Abel, Enos, and sisters with Aâc, Coh, Cáy, Moo, and Nicté, and the Egyptian Set, Osiris, Aroeris, Isis or Mau, and Niké; or that *Sougrivâ* is merely a Hindu Aâc, and *Bâli*, Coh! Even the names in each account are synonymous. No one familiar with philology can deny that A-bâl—A-bâl—Bâl-i—Bâl-âm are identical words. A, the contraction of Ah, is the Maya masculine article *the*; Bâl is the radical of Bâl-âm, and Bâl-âm is for the people of Yucatan to-day the *Yumil-Kaax*, "Lord of the Fields," or "Leopard," the title and totem of the unfortunate Coh. In Egypt the leopard's skin was always a part of the ceremonial dress of priests; in Greece and Chaldea it appears as an appendage of the Mysteries; it was worn by Nimrod and Bacchus, two prototypes of the murdered Prince, and invariably hung suspended from the altars and shrines of Osiris; and when the latter appeared as sovereign lord of Amenti, or the "*Land of the West*," his symbol was a leopard reclining beneath an open eye. *A crouching leopard with human head, the ear tablets of which bear the name of Coh, has recently been unearthed among the ruins of Chichen!* Again, the leopard's skin is mentioned by the Brahmins in connection with the prayers of *Ayâtreyâ Brâhmânâ*, and employed in the *âgnishtomâ* of the Soma Mysteries to envelop the neophyte who is to be "*born again*," and "*out of which he emerges as from his mother's womb*." (By comparing with Appendix N further clew may be had to the esotericisms of both the Old and New Testaments.) Osiris or Osir appears to be derived from the Maya verb *Osil*, equivalent to "dearly beloved," a title that often accrued to Coh because of the love borne him by his sisters, and that manifested by the people generally whose hero he was.

Cain, Set, Sougrivâ, and Aâc are all expressive of the individual. The first is derived from Cân, the title of Maya rulers and also of the rulers of Central Asia from Burmah to Thibet to this day (*Khân*). Set is the cognate of the Maya Ze, "to abuse with blows," an appropriate title for one who murdered his two brothers with strokes of a spear, and when the fortune of war placed his sister Moo in his power, first violated her, then kicked her to death, as is the account given by the *Troano* MS., and Aâc's palace in Uxmal represents him with the heads of Coh, Cáy, and Moo at his belt, and their flayed bodies at his feet. Sougrivâ is made up of three Maya primitives, *suc* ("quietly"), *lib* ("to ascend"), and *hâ* ("from water"), the *turtle*, in fact. Set, for his crimes, in Egypt was denominated *Nubti*, an Evil principle, or, according to the Maya language, the "*Adversary*."

L.

From time immemorial the Egyptian priests carefully preserved among the archives of the temples and sacred colleges faithful accounts of all events deemed worthy of a place in history. They derided the Greek philosophers for their belief in the universality of the deluge of Deucalion, averring there had been several local

catastrophes of like nature. When Solon sought the wisdom of the temples of Delta, he was told that the greatest cataclysm ever known resulted in the destruction of a continent lying off the Pillars of Hercules (Gibraltar), in the Western Ocean, as the sequel "to violent earthquakes and deluges (tidal waves), which brought desolation in a day and a night," when "the land was plunged beneath the sea and entirely disappeared." They placed this event at nine thousand years before the date of narration, or somewhere about ten thousand years before our era. Not only does the same account appear in the *Troano*, but it is also carved in intaglio over the interior door-way of the rooms of the sacred college at Chichen, and specified as *Akâb-ib*, or the "terrible writing." It is not improbable that it was the fate of Atlantis that gave rise to the Chaldean, Chinese, Aryan, Greek, and Polynesian traditions of a deluge, and the narrations of the Sibylline and Phœnician oracles. Rev. Dr. McClintock justly remarks that the curious coincidence between the traditions of the two hemispheres is "explicable only on the hypothesis of some common centre." (See "Biblical, Ecclesiastical, and Theological Cyclopædia," vol. ii. p. 732, *et seq.*) That the peoples of the East had found the means of communicating with the present continents of America long before the time of Columbus or the Norse adventurers is evident from the fact that "*black people*" existed at and about the Isthmus of Panama at the time of the first arrival of the Spaniards; and portraits of such have been discovered in Uxmal, Ake, Chichen, Tula, and Teotihuacan.

M.

A sole and omnipotent Deity, the Creator of All Things, appears to have been the universal belief of the earliest ages. This the Chemitic priests termed *Kneph*, placing superior to the Triads. In Chaldea, "daughter of *Posidon*, king of 'Lands beyond the Sea,'" in spite of the apparent polytheistic character of religion, a Supreme was recognized as *Râ*, "the eternal truth" (*Lâ* of the Mayas), to which also a trinity was subjective. The "*Niroukta*," one of the sacred books of the Hindus, declared there were "three gods" that, however, "designate but one deity,—*Maha-atma*,—Soul of Souls." Tao-Tse, a contemporary of Confucius, wrote, "Reason produced *One*; one produced *Two*; and both produced *Three*." Again, among ancient Peruvians, *Pacha-câmâc* was designated as the head of a trinity composed of Himself, *Con*, and *Uiracochâ*; and the Quiches declared all things existed by reason of *Tzâkol*, whose names are *Bitol*, *Alom*, and *Qaholm*,—the "Constructor," the "Engenderer," and the "Giver of Life."

These conceptions concerning a triune Deity, preserved in the works of the early philosophers, have descended to the present, but we nowhere learn their precise origin. If the ancient priests knew, they carefully concealed the fact; and the "Fathers" of the Church manifestly were equally in the dark, being satisfied with appropriating as an unfathomable mystery, and imposing as a dogma. (See Draper's "*Conflict of Religion and Science*," p. 53.) Indeed, so little was the subject understood that for a time it was a wrangle who should be named as the least and last of the triad, the Virgin Mary having a numerous and influential support. ("Bib. Theolog. and Eccles. Cyclopædia.")

The conception of the Creation that obtained among

the ancient people of Mayax is well told in a tableau sculptured on the east façade of the palace at Chichen. It represents a luminous egg, emitting rays and floating in the midst of the waters where it had been deposited by the Supreme Intelligence. In the egg is seated the Creator, his body painted blue, in his hand a sceptre, a plume of feathers surmounting his head, and his loins wound with a broad falling girdle; he is surrounded by a serpent, symbol of the Universe. Porphyrus's account of the Orphic *Mysteries* would serve as an explanation to this. To the initiated, Jupiter is represented "as a man seated, alluding to his immutable essence; the *upper part of the body naked*, because it is in the skies the Universe is most uncovered; *clothed from the waist below*, because terrestrial things are most hidden; *with a sceptre in his left hand*, because the heart is on that side and the organ that regulates the life of man." Says M. Le Plongeon, "The philosophers of Mayax probably knew the waters covered three-fifths of the globe, and that water being a combination of gases, the most subtle of fluids, must have been the first form of matter produced. This is why, on each side and on the top of the tableau, they placed the symbol of water, taking care to leave without it, at the upper part, a portion equal to *two-fifths* of its length. In the midst of the waters they represented the figure of an egg, because their study of physiology had made them acquainted with the fact no being exists on Earth that is not born from an egg. The egg emits rays of light into which, says Thoth, 'all things resolve themselves,' and that, says the *Popol Vuh*, 'appeared on the water as an increasing brightness that bathed the Creator.' Notice also that the symbols of water terminate with the head of serpents, because they compared the waves of the ocean to the undulations of the reptile's body while in motion. For this reason the Mayas named the sea *Cânâh* the great, the powerful serpent; and in the *Troano* the sea is always designated as a serpent's head. This explains why the Mayas, Quiches, Egyptians, Hindus, etc., represented the world, and by extension the maker of it, as a serpent. Thus it is that they placed a serpent within the egg, behind the Creator, to indicate this symbol is the totem of the ancestor of all beings. And here we have one of the origins of serpent worship,—that is, adoration of the Creator." The Egyptians called the creative power *Kneph*, from *Kâneh*, a cognate of Can-hel (serpent), and said he threw from his mouth an egg in which was another god, *Phthâ*. *Phthâ*, or *Thâh*, in Maya signifies the "worker," hence maker or creator.

Either the Maya, Quiche, or Egyptian account might be accepted as a translation from the "Manava Dharma Sastra," a book compiled from other and more ancient works of the Brahmins, somewhere about 1300 B.C. (H. T. Colebrook). This work further declares, "In the beginning was nothing but darkness. Then the great self-existing Power dispelled the darkness and appeared in all his splendor. He first produced the waters, and on them moved *Narayana* the divine spirit." Compare this with *Genesis* i. 1-4. Then with the Chaldean account, "In the beginning all was darkness and water; and therein was generated. . . . animals and . . . forms. Thalath ruleth them all." (The Chaldee *Thâlâth* (woman), Greek *Thalassa* (sea), is the Maya *Thâllâc*, "thing without steadiness.") The Hermitic version is, "There was boundless darkness, and water and a subtle spirit, intellectual in power, existing in chaos. But the holy light broke forth, and the elements were produced from a watery essence." The

Chemitic record declares, "All things had resolved themselves into light . . . the earth nowhere appeared" (Primander). And the Quiche, "Everything was without life, calm and silent; . . . void was over the immensity of the heavens . . . only the tranquil sea was, and the space of the heavens. All was mobility and silence and darkness; only the Creator, the Maker, the Dominator—the Serpent—they who engender, they who create, were on the waters as an ever-increasing light."

Whatever may be the view taken of the subject, it can hardly be argued that this identity of ideas is purely accidental.

N.

The following extracts are adapted from "Sacred Mysteries of the Mayas and Quiches":

BOOK OF ENOCH: "A spacious habitation built with stones of crystal. The roof had the appearance of agitating stars, and flashes of lightning. Flames burned about its walls, its portals blazed with fire. The dwelling was hot as fire,—cold as ice. . . . Then I went to another habitation, more spacious than the former. Every entrance which was opened before me was erected in the midst of a vibrating flame. . . . Its floor was on fire; above were lightnings and agitating stars, whilst its roof exhibited a blazing fire. . . . One of great glory sat upon the orb of the brilliant sun. . . . A fire of great extent continued to rise before him. (Chap. xiv. ver. 12, 14, 18, 24.) . . . They raised me up into a certain place where there was the appearance of burning fire; and when they pleased, they assumed the likeness of men. . . . And I beheld the receptacles of light and thunder at the extremities of the place. There was a bow of fire, and arrows in their quivers . . . a sword of fire, and every species of lightning. (Chap. xvii. ver. 1-3.) . . . Then I passed into another terrific place . . . where I beheld the operation of a great fire, blazing and glistening in the midst of which there was a division . . . columns of fire struggled together to the end of the abyss, and deep was their descent. . . . This was the place of suffering. (Chap. xxi. ver. 4, 5, 6.) From thence I proceeded to another spot, where I saw on the West a great and lofty mountain; a strong rock, and four delightful places." (Chap. xxii.)

Again, Henoch gives us an elaborate account of how, with the help of his son Mathusaleth he constructed a dwelling deep in the bowels of a mountain in the land of Canaan, in imitation of the nine vaults shown him by Deity, each apartment being roofed with an arch, the apex forming a keystone, upon which were engraved mirific characters, each of the nine letters representing one of the nine words emblematic of the nine attributes of God. He then constructed two triangles of pure gold, tracing on each two of the mysterious characters; one of these was suspended within the deepest arch, the other given to Mathusaleth, to whom he imparted "*important secrets*." Note that all this is in consonance with the esoteric rules and teachings of the Mysteries, and that the structure corresponds to the plan and architecture of the temples of Yucatan and the Nile.

The initiation at *Xibalbá*, in the heart of the mountains of Guatemala, consisted of seven ordeals, according to the *Popol Vuh*: 1. Crossing the rivers of *mud*, followed by that of *blood*; journeying the *white, red, green, and black* roads, and the salutation of the twelve veiled *Mystai*; the detection of the false or dummy *Mystikos* in their midst; the scorching that accrued to those who ventured to recline in the presence of the

august assemblage when so invited, the seat being a hot stone. 2. The "Dark House," where for the space of a night a lighted torch must be maintained, yet returned whole at the termination of the ordeal; terrible chastisement, even death, in each instance awaited those who failed. 3. The "House of Spears," where for twelve hours the candidate was obliged to defend himself from the attacks of an expert spearman; and also to provide four pots of rare flowers without outside communication, or bringing with him. 4. The "House of Ice," where the cold was intense, yet had to be borne from darkness until daylight. 5. The "House of Tigers." 6. The "Fire House," a burning furnace, the heat of which must be borne from sunset to sunrise. 7. The "House of Bats," full of death-dealing weapons, and the dwelling of *Camazotz*, the Cheiropteran god, who appeared and beheaded the candidates if off their guard.

"Do not the terrors of Xibalbá recall the visions of *Henoch*?"—remarks Doctor Le Plongeon,—"The blazing house of crystal, burning hot and icy cold—that place where were the bow of fire, the quiver of arrows, the sword of fire—that other where he had to cross the babbling stream, and the river of fire—and those extremities of the earth full of all kinds of huge beasts and birds—or the habitation where appeared one of great glory sitting upon the orb of the sun—and lastly, does not the tamarind-tree in the midst of the earth that he was told was the Tree of Knowledge, find its simile in the calabash-tree in the middle of the road, where those of Xibalbá placed the head of Hunhun Appu after sacrificing him for having failed to support the first trial of the initiation? Even the title—*Häch-mâc*—of the high priest in Mayax, that we see over the bust of High Pontiff Prince *Cây Cànchi*, son of King *Cân* at Uxmal, recalls that of the chief of the Magi at Babylon. Do not also the awful ordeals of Xibalbá seem an exact counterpart of what happened in milder form at the initiation of Eleusis or the greater Mysteries of Egypt from which they were copied? Does not the recital . . . recall to mind the wonderful similar feats said to be performed by the *Mahâ-âttmas* in India, and of several of the passages of the book of Daniel, who had been initiated to the mysteries of the Chaldean Magi? Will it be said that the Mysteries were imported from Egypt, Chaldea, India, or Phœnicia to America? Then I will ask when? By whom? What facts can be adduced to sustain such assertion? Why should the words (*Con-ex Omon Pân-ex*) with which the priest at the conclusion of the ceremonies of Eleusis, and the Brahmins at the end of their religious ceremonies, dismiss the attendants, be *Mâya* instead of Greek or Sanskrit?"

PORT HURON, MICHIGAN.

A CONVENIENT FORMULA FOR THE TREATMENT OF DIABETES BY LITHIUM IN PILL FORM.

VIGIER recommends the following as more convenient than Martineau's arsenical liquid containing lithium:

R Lithii carbonat., gr. iss;
Sodii arseniat., gr. $\frac{1}{2}$;
Ext. gentian., gr. $\frac{1}{2}$;
For each pill.

To be taken morning and night, and continued until sugar has disappeared from the urine.

THE DANGERS OF ANTIPYRIN.

IT has almost seemed as if history was repeating itself in the case of antipyrin. Like all other drugs enthusiastically received by the profession, and in many cases truly unworthy of the recommendation that they have received, antipyrin is only now, several years after its introduction, commencing to show its disadvantageous side in a stronger light. Scarcely a journal comes before us which does not contain some mention of the unfavorable results which have followed the use of antipyrin. In addition to the fatal case referred to in the GAZETTE for 1885, p. 257, we have recently seen a record of at least one death produced by its use, although the authority for that statement has escaped our memory, innumerable cases where untoward results have been produced, and several cases where cyanosis, vomiting, disturbed respiration and circulation have followed doses which, in other circumstances, have been administered with impunity. Guttman, to whom especially we are indebted for a great deal of valuable information as to the action and indications for the use of this

drug, in the *Therapeutische Monatshefte*, June, 1887, calls attention to two striking cases, in which, in his own experience, alarming results followed the use of antipyrin. Numerous cases are on record where collapse has followed the use of antipyrin in doses of 45 or 30 grains,—the doses recommended by Filenhe, its discoverer,—but in one of these cases of Guttman's, in a few minutes after the administration of a dose of 15 grains, cyanosis of the face, increased respiration and pulse-frequency, dyspnoea, and sensations of extreme heat over the entire body, made their appearance. In a few hours these symptoms had disappeared under the internal use of camphor, and applications of mustard over the breast and calves of the legs and an ice-bladder over the heart. In another case similar appearances came on after the same dose, with the addition of oedema of the arms and hands,—symptoms which, in spite of treatment, continued for three days.

Without attempting to give the statistics of similar cases, which we do not doubt have come before the attention of all readers of medical journals,—and perhaps the experience of most practising physicians is not free from such unfavorable results,—it does not follow that antipyrin is necessarily in danger of losing its prominent position. As is well known, most of our powerful remedies are found, in certain individuals, productive of the most serious results after the administration of the smallest doses. Such idiosyncrasies are frequently met with, and our desire is only to attract attention to the fact that antipyrin cannot be administered to every one in the usual doses with impunity. These idiosyncrasies can only be guarded against by the most extreme care in the commencement of the use of any drug. We would therefore recommend that wherever antipyrin is used for the first time the dose should never exceed 10 grains (and perhaps even $7\frac{1}{2}$ would be better) until it has been found that no serious action follows its use. In fact, it is very doubtful to our mind whether the dose should ever exceed 10 grains, since common experience seems to show that the reduction of temperature is not in direct proportion to the size of the dose, but that, in fact, after large doses sometimes the temperature may rise instead of falling.

In this connection it may be mentioned that at a recent meeting of the New York Pathological Society, Dr. Porter (*New York*

Med. Journ., July 30, 1887) presented the liver and kidneys of a patient to whom large doses of antipyrin had been given, in which, as a result of the action of that drug, it was thought, extensive fatty and granular metamorphosis had taken place. The patient had had only a moderate attack of rheumatism with some elevation of temperature, for the reduction of which pretty full doses of antipyrin were given at rather short intervals. It did not seem to affect the temperature very much. After the patient entered the hospital the temperature went up to 105° F., and following the use of antipyrin it went up to 107° F. The use of antipyrin was then stopped, and salicylic acid was administered. The temperature then fell to 103° F. Antipyrin was given again, and the temperature rose again. Antifebrin also was used, but the temperature went higher and higher, and the patient died with a temperature of 109° or 110° F. The speaker had seen in literature that men who had experimented with antipyretics, such as antipyrin, antifebrin, and thallin, had found extensive changes in the liver and kidneys, and during life casts and albumen in the urine, but they maintained that it was of no practical importance. They also had made the observation that patients treated with these antipyretics recovered less quickly, especially patients with typhoid fever, the duration of the disease being about forty-two days, whereas in those treated with other antipyretic measures, such as baths, it lasted only about thirty-two days. One writer had said that when he used antipyrin he succeeded in getting the highest death-rate, but he was inclined to think the patients were more comfortable while they lived. The speaker had noticed for some time that in the bodies of patients who had been treated with antipyrin there was very frequently granular and fatty metamorphosis of the liver and kidneys. He had, therefore, come to believe that antifebrin, antipyrin, and thallin were not such safe antipyretics as had been maintained.

BETOL—A NEW ANTIRHEUMATIC REMEDY.

THE substitutes for salicylic acid and its salts, which are continually increasing in number, appear to have received an important addition in the introduction of a salicylic ether of naphthol, which has been recommended by Sahli, who our readers will remember likewise introduced salol into the therapeutics of rheumatic affections (*Therapeutische Monats-*

hefte, June, 1887). To this substance Sahli gives the name of betol, and like salol, which divides into salicylic acid and phenol, it splits up in the organism into salicylic acid and naphthol.

Betol appears to possess the advantage over salol in freedom from odor and taste. It contains, however, ten per cent. less salicylic acid than salol, and has likewise the disadvantage of possessing a much higher melting-point (95° instead of 43° C.), a point which is of importance, since the readiness with which such compound ethers split up into their component parts is dependent upon the lowness of their melting-point.

The conditions under which this remedy may be applied do not yet seem to be clearly established, since Sahli states that while he has in numerous cases of articular rheumatism, neuralgia, etc., employed betol with most successful results, in other cases its use has been followed by no improvement. In the latter instances, examination of the urine has shown, by the absence or faintness of the salicylic acid reaction, that the preparation did not become decomposed, as it must do to produce any therapeutic effects. Betol is readily soluble in fluid fats, and Sahli recommends the administration of this substance in solution in oils, with the hope of facilitating its decomposition, since it is known that the melting-point, and therefore the point of decomposition, is lowered by the presence of certain organic bodies.

Kobert, in the preceding number of the same journal, has likewise published a paper on this subject, in which he, almost without qualification, gives the preference to betol over salol, especially in its freedom from disagreeable after-effects. Sahli regards this position as, however, not yet proved. He has given betol in amounts varying from 2 to 12 grammes (15 to 180 grains) in the twenty-four hours, the latter in a six-year-old child. In some instances he has found the most marked effects from the smaller dose, while in other cases the larger amounts have appeared entirely inert. He therefore thinks that in our present imperfect knowledge regarding this substance, betol cannot yet take the precedence over salol on account of its smaller percentage of salicylic acid and its more difficult decomposition; so, also, the substitution of the inactive naphthol for phenol is to be regarded as a disadvantage, since the action of salol is not to be attributed solely to the salicylic acid but also to the phenol, which especially appears to be of value in the treat-

ment of neuralgia. Nevertheless, on account of the freedom from disagreeable odor and taste, betol appears to be well worth further study to establish the conditions in which it is of value and to determine the correct method of its administration.

Kobert, who describes this preparation under the name of naphthalol, found it very useful, and at least as valuable as other medicaments, in various forms of catarrh of the bladder, especially in gonorrhœal cystitis, with alkaline decomposition of the urine. The urine soon became clear and acid, the formed elements in it were diminished in number, and the pains of the patients became easy.

A NEW LOCAL ANÆSTHETIC.

NO physician nowadays can claim to eminence in the medical profession unless he has discovered a local anæsthetic. There is no doubt in our mind that this fact is universally recognized. Witness the innumerable claims to the dignity of a new anæsthetic continually before us. The last candidate for these honors appears to be a joint discovery by a veterinary physician, Mr. Goodman, Dr. A. M. Seward, of Bergen Point, N. J., and Dr. J. Herbert Claiborne, Jr., of New York. Mr. Goodman was first on the scent by noticing the apparent anæsthetic properties of a poultice made from a pile of leaves raked haphazard from the ground. Dr. Seward, according to Mr. Claiborne, discovered an alkaloid in some leaves submitted to him by Mr. Goodman, and he terms the alkaloid, of which the process of extraction is not given, stenocarpine. It appears, however, that the botanical name of the tree from which this substance is derived is unknown. According to Mr. Goodman, the source of the leaves employed by him is known in Louisiana, the locality where this substance was first employed, as the tear-blanket-tree.

It grows to the height of thirty-five to forty feet, with a diameter to the bole of about eighteen inches and a spread of foliage of about thirty to thirty-five feet. The leaves resemble those of an acacia. The bark is smooth. From the ground up the tree is furnished with clumps of forked spines or thorns, the parent spine springing at right angles from the bough or trunk. Though Mr. Goodman is a native of the region, he has never seen the tree blossom. As fruit it bears pods eight or ten inches in length, flat

and slightly curved, containing seeds and a viscid juice.

The spines are very tough and highly polished, and the wood is extremely tough. It grows in clumps and singly, and is abundant in Louisiana.

From the likeness of the tree to the *Acacia stenocarpa* Dr. Seward dubbed the new alkaloid stenocarpine. It would have been better, however, to withhold the naming of the alkaloid until the botanical name of the tree had been known.

Dr. Claiborne's share consisted in clinical experiments with the substance supplied him by Dr. Seward. According to Dr. Claiborne (*Medical Record*, July 30, 1887), two drops of an aqueous solution produced in a few minutes complete insensibility of the cornea and conjunctiva, with dilatation of the pupils, the anæsthesia lasting for about half an hour, the dilatation of the pupils for thirty-six hours. This substance would even appear to be more efficacious than cocaine as an anæsthetic, for Dr. Claiborne reports instances in which the application of a few drops of a two per cent. solution on the skin produced almost absolute anæsthesia, so as to permit the painless removal of tumors, warts, etc. In the nose also applications produce complete anæsthesia, and in the case of the ear, the instillation of a few drops permitted the touching of the drum-membrane without pain.

As to whether we are to have another disappointment in this case or not the future alone can tell.

SOLANIN.

AS the readers of the GAZETTE may remember, though discovered in 1821 in potato shoots and in the parings of young potatoes, solanin has been only recently introduced into medicine by Dr. Geneuil, who employed it in subcutaneous injections in sciatica and other forms of neuralgia. Continued experience has, however, proved that so employed solanin injections are extremely irritating, and Geneuil therefore came to the conclusion that solanin possesses caustic action, and he recommended it to be employed only hypodermically in cases where a tolerably severe revulsive was desired.

The subject has again been investigated by M. Adrian, who presented his results to a recent meeting of the Société de Médecine Pratique (*Les Nouveaux Remèdes*, June, 1887). He has found solanin is not an alkaloid but a glucoside, and if solanin is dissolved in an acid,

the entire amount of acid may be recovered in its free state, while the solanin splits up into glucose, and a new base, still imperfectly known, which he terms solanidiné. It follows from this that it is incorrect to speak of solanin salts, and injections made of acid solutions of solanin owe their escharotic properties to the free acid. Nevertheless, it appears that solanin possesses decided analgesic properties.

In the thesis recently published by M. Gairnard, he there states as the result of the experiments which he has carried out under Professor Dujardin-Beaumetz, and with Dr. Bardet, that solanin, obtained from the germs of the potato, is possessed of incontestable anæsthetic properties, and is almost free from toxic effects, as much as 15 grains of solanin being required to kill a small rabbit. It is, of course, possible that solanin obtained from different species of Solanaceæ may contain atropine or other allied alkaloid, which will, perhaps, explain the character of the results produced by it. The subject is well worthy further study.

*QUILLAJA ACID—A CONTRIBUTION TO
OUR KNOWLEDGE OF THE
SAPONIN GROUP.*

KOBERT, of Dorpat, Russia, contributes an elaborate article under the above title to the *Archiv für Experimentelle Pathologie und Pharmakologie*, 23 Band, 3 u. 4 Heft, of which the following is a concise abstract:

In 1782 Molina described a Chilian tree whose bark gave to water a biting taste, and which he called *Quillaja saponaria*. It is generally counted among the Rosaceæ, although Brown has pointed out marks of difference. The bark of the tree was soon known as "washwood," or "panamarinde." Sections made through the bark show masses of crystals of calcium oxalate and a network of fibrous tissue. The active principle is contained in formless masses of dark-colored substance, contained in the cells of the parenchyma of the bark. Concentrated sulphuric acid turns this substance first yellow, then bright red, and finally a violet-blue. Early analyses of the plant, after the method of Schroder and others, seemed to demonstrate the identity of saponin with the so-called Egyptian soap-root, the quillajarinde of Henry and Boutron-Charlard, and also the common senega-root, together with other common plants with which we had long been familiar. The importation and use of the Egyptian plant were lessened by the cultivation of the native sources of saponin.

Kobert's analyses of various sources of saponin, from different sources, convinced him that the saponin of various authors is not a simple body, but a combination of at least two substances not easily separated. He found that the separation of saponin by precipitating it with barium was wholly worthless, as the efficiency of the drug was thus more or less impaired. He was led to conclude, however, that the process of obtaining the active principle by its combination with acetyl gave a substance whose poisonous adjuvants were thus destroyed; it was more reliable than the barium process. Pure saponin he found to be a tasteless substance, of un-irritating odor, and free from poisonous properties; the symptoms of poisoning following the use of the drug were caused by its mixture with other substances. By a method whose most important steps were concentration of a solution from the boiled bark, precipitation by acetate of lead, the removal of coloring-matter by chloroform, and finally drying the precipitate from a clear solution over sulphuric acid in a vacuum, Kobert obtained a powder, of acid reaction, which he called quillaja acid. With its alkaline salts it is in water, carbonates, and caustics readily soluble. By treating it with alcohol and chloroform crystals may sometimes be obtained, but this happened too infrequently to admit of analysis of the crystals. Only the free acid is soluble in alcohol; this solution will take five times its bulk of chloroform before precipitating the solid. A test between pure saponin and sapotoxin and common commercial saponin lies in the fact that the latter are very little soluble in absolute alcohol. In methyl alcohol quillaja acid is easily soluble; in ether insoluble; in chloroform sparingly soluble by warming. This acid and its alkaline salts hold insoluble powders so well in suspension that their filtration is difficult. It may be best combined in emulsions, as the French have found. Copper sulphate, ferric and mercuric chlorides, ferro- and ferricyanides of potassium, and other allied salts do not precipitate it. Solutions are readily decomposed by bacteria, and germs grow readily in them. Concentrated sulphuric acid colors quillaja acid a beautiful dark red. Further experiments show it to be a glucoside, turning polarized light towards the right; it is found to be a glucoside acid, resembling ergotin acid. Pepsin, pancreatin, ptyalin, and diastase do not decompose it. It was found that quillaja acid and saponin differ in that the latter is an impractical modification of the

former. The formula $C_{19}H_{30}O_{10}$ corresponds to the results of analyses, and it is composed of about one-third of sapogenin and two-thirds glucoside; its acidity is exceeded thirty-five and one-third times by sulphuric acid. Although many have written regarding this substance, yet few have used it therapeutically, and it has as yet no therapeutic literature proper.

A case of poisoning from the drug has been reported by Lessellier. The symptoms were rigors; epigastric cramp; cold sweats; tremors; syncope, which soon disappeared; a small pulse; skin moist; excessive vomiting; anxiety and distress referred to the præcardium; vesical tenesmus, and increased secretion of urine. These symptoms disappeared under expectant treatment in three days. The sodium salts of quillaja acid have a strongly acrid taste. A five per cent. solution applied to the throat promotes salivary flow, and produces great irritation; profuse nasal and lachrymal secretion are caused when the same solution is applied to the nasal passages. In the larynx convulsive cough is produced. A minute particle of the substance, or a drop of two or five per cent. solution, brought in contact with the conjunctiva, produces burning, intense pain, followed by œdema and pus-formation. The pupil is contracted, from irritation; the cornea does not generally become involved, and in five hours after the application the swelling has disappeared. Strong solutions, when painted on the external skin, are inert, but application by ointment with friction produces erythema, with itching and burning, and, if the application be continued, a pustular eruption. The tissues of the frog, when brought in contact with the substance in solution, lose their vitality much more rapidly than commonly. Blood-corpuscles are dissolved or disintegrated by the substance in solution; it is a poison to protoplasm, and injures the vitality of the tissues when brought into direct contact in solutions of even one-half per cent. For injection into the blood a solution of one-tenth per cent. was taken. In fatal cases it was often impossible to find post-mortem changes; death resulted evidently from cerebral paralysis, and paralysis of the respiratory centre. Post-mortem changes were most generally found in the upper and lower portions of the small intestine, and consisted of excessive hyperæmia, profuse secretion, and thickening of the mucosa. Extravasation of blood did not occur, but the capillaries were enormously distended. The toxic effects often

went much further than this, and extensive degeneration of the glandular structures of the intestine resulted. A noteworthy phenomenon was the formation of hyaline material about the villi, and the decomposition of the blood. The large intestine showed similar effects in less degree. Endocarditis, especially about the valves, was often present. There was œdema of the hepatic duct and gall-bladder. The urinary bladder and pelvis of the kidney were occasionally the seat of the same changes as the intestine. The urine was full of blood and cystic debris. Hæmoglobinuria and albuminuria were often present. Quillaja acid itself was not found in the urine. Changes in the kidney-structure itself were rarely found, although there was good reason to expect them. The liver was generally slightly enlarged, but not greatly affected. The mesenteric glands were also swollen. The muscles of the general muscular system, and also the heart-muscle, were not affected. As has been stated, the heart-valves were roughened, and at their bases there was swelling and œdema. At the early stages of the poisonous effect no diminution in blood-pressure was observed, but in the later stage of coma a complete vaso-motor paralysis was observed. When the fatal dose was so small that no intestinal lesions were observed, nothing else pathological could be observed, and the fatal result was ascribed to paralysis of the cerebral ganglia by an agent which by repeated circulation in the ganglion-cells successively paralyzed them. In the slowness of its action the drug resembled the heavier metals which are poisonous. The largest fatal dose given was $\frac{1}{1000}$ part of the weight of the animal experimented upon; the smallest dose was $\frac{1}{100000}$ of the body weight; and when the dose was reduced to $\frac{1}{100000}$ part of the animal's weight, recovery was the result. After the injection of large doses of the poison into the blood it could not be certainly identified in the urine. It has been shown that quillaja, when compounded with sodium, in solution of $\frac{1}{10000}$, dissolves blood-corpuscles. Hæmoglobinuria was not observed frequently, irregularly only, and it was found that the liver was somewhat distended by decomposed blood-corpuscles after the poison had been injected into the blood. In cases where no changes were observed in the intestines it was found that the number of red corpuscles was diminished, and the intestinal changes were thought to be due more to decomposition of the blood than to any change originating in the intestine. Although this

drug was so poisonous when injected into the blood, when given by the mouth it was much less active. A rabbit took $\frac{1}{1000}$ part of its body weight of the drug without any symptoms of poisoning; another took $\frac{1}{1800}$ part of its body weight with no worse result than diarrhoea for two days. The intestinal symptoms following death from the drug, when given by the mouth, were wanting, a notable difference from its effect when injected into the blood. Kobert reckons that five hundred times as great a dose can be taken by the mouth without injury as can be given by injection into the blood; this depends upon the very slow rate of absorption of the poison by the intestine. It is not decomposed by the ferments of the pancreas, stomach, and saliva, for it was found in the fæces. The subcutaneous injection of the drug was practised upon frogs, on whom between $\frac{1}{2}$ and $\frac{1}{3}$ of a grain produced fatal effects. A notable effect of poisonous doses subcutaneously was ideomuscular contractions, which persisted in the skeletal muscles for twenty-four hours after life had apparently ceased; rigor mortis subsequently ensued. In warm-blooded animals injections subcutaneously caused great pain, with local hemorrhagic inflammations, with a tendency to abscess-formation and œdema. The injected fluid could be found after several days in the fluid of œdematous tissues. Fatal effects followed such injections very tardily, showing the slow absorption of the poison. Intestinal changes were not often observed. Several hemorrhages were seen beneath the pleura in one case. The dose was in one case of poisoning by subcutaneous use $\frac{1}{1000}$ of the body weight. In cases where the poisonous symptoms were slow in development, minute hemorrhages were found in the subserosa of the intestines.

In distinction from quillaja acid saponin was found almost non-toxic, having but feebly the effects of the acid, although decomposing to some extent blood-corpuscles. It was thought to be at least thirty per cent. weaker than quillaja acid.

Reports on Therapeutic Progress.

INTUBATION OF THE LARYNX.

Intubation of the larynx was recently made the subject of debate before the New York Academy of Medicine, and we lay before our readers a full abstract of the papers read, as published in the *Boston Medical and Surgical Journal* for July 28, 1887.

DR. F. HUBER read a paper based on a study of forty-seven cases, the results of which had convinced him, he said, that at the present time tracheotomy should only be resorted to in cases in which intubation had failed to afford the needed relief; and he was of the opinion that a case of this kind would seldom be met with. Having stated that the dyspnœa was as effectively relieved by intubation as by tracheotomy, he spoke of the advantages of the former, and also referred to the origin of the procedure as proposed and practised by Bouchut in 1858. Then, after referring to some practical points derived from his personal experience, he said that intubation had now passed through the experimental stage, and that its utility had been fully established by numerous operators in different parts of the country. Notwithstanding the gratifying results obtained, however, it had as yet received very little favor, or even attention, in Europe.

Of his forty-seven cases, Dr. Huber said that twenty-nine, with eleven recoveries, were in children under three years of age, and eighteen cases, with nine recoveries, in children of three years or over. Of the children under three years, one was nine and one-half months; one, ten and one-half months; two, eleven months; one, one year; two, two years; two, two and one-half years; and two, two years and eight months old. Of all the children that he had been called upon to treat, who were suffering from laryngeal stenosis, he had found it necessary to resort to intubation in only one out of every three or four cases, and he thought that it should not be practised until dangerous symptoms had supervened. He used it, in fact, in exactly the same class of cases in which one year ago he would have performed tracheotomy. Having spoken of the diagnosis of croup and the indications for surgical interference, he referred to the importance of making a careful examination of the neck and chest, and said that he had known cases of retro-pharyngeal abscess and empyema to be mistaken for laryngeal stenosis. As confirmatory of the diagnosis of the latter, relative absence of fever, in uncomplicated cases, was of much value; and aphonia, with difficulty of both inspiration and expiration, was positively indicative of croup.

He next spoke of the various accidents and mishaps which had been met with in connection with intubation, and the objections raised against the procedure. He referred first to the gag, and said that O'Dwyer's gag was

liable to be displaced by the struggles of the patient, but that this was not the case with the one devised by Dr. Denhart, which he exhibited. The thread attached to the tube should be eighteen or twenty inches in length, and, if not withdrawn at once, should be passed over the ear and secured. In order to avoid accidents in introducing the tube the efforts to place it in position should be short and repeated, rather than kept up uninterruptedly for any length of time. One of the most serious accidents that could occur was the pushing of dislodged membranes before the tube, and in a case of this kind Dr. E. D. Ferguson, of Troy, was obliged to resort to tracheotomy.

Several deaths had been reported from this accident, and Dr. Waxham had recently devised a long tracheal forceps for the purpose of removing the membranes when it occurred. In a case of his own in which it happened he gave the child brandy, with the effect of exciting a fit of coughing which expelled both the tube and the membranes. If, at any time after the tube had been introduced, noisy breathing should set in, it was an indication for the temporary removal of the tube. The tube had been known to be coughed up and then swallowed. Instances had also been reported in which the tube had slipped through the larynx into the trachea; but this was when the earlier pattern of tube, with small head, was employed. The tube did not act as a foreign body when in the larynx, giving rise to choking sensations and coughing; but if it remained in position for a considerable length of time it might possibly produce slight ulceration. This, however, did no harm.

As to the time for removing the tube, in some cases this might be done as early as the fourth or fifth day, although it was often desirable to allow it to remain longer. As a rule, however, it could be dispensed with at a much earlier date than the tracheotomy tube. If the respiration continued free, the tube should generally be allowed to remain until the fifth or sixth day; but if the respiration became noisy it should be promptly removed, and afterwards reintroduced, if this should prove necessary. When there were diphtheritic patches discernible in the nose or pharynx it was advisable, as a rule, to leave the tube in position until they had disappeared.

In intubation, as in tracheotomy, the prognosis was more favorable when there was simply local obstruction in the larynx than in cases where there was marked constitutional infection from the diphtheritic poison. No age offered a contraindication to intubation.

No positive prognosis should ever be made, however, until forty-eight hours had elapsed from the time of insertion of the tube.

As regards medicinal treatment, Dr. Huber said that it was his practice to keep up the use of bichloride of mercury throughout the course of the disease, whether intubation were resorted to or not. He employed it, in accordance with the views of Dr. Jacobi, in larger doses than those usually recommended, giving from $\frac{1}{2}$ to $\frac{1}{4}$ a grain, and in severe cases as much as 1 grain, in divided doses, during the twenty-four hours. When there was much difficulty in swallowing, he gave it in the form of tablet triturates, of $\frac{1}{16}$ of a grain each, mixed with sugar and placed dry upon the tongue. If there were extensive diphtheritic membranes in the fauces he also employed tincture of iron and chlorate of potassium. In threatened heart-failure he resorted to brandy, caffeine, etc. If the temperature was very high, antipyretics were employed either by the mouth or rectum. Finally, he used the steam atomizer for producing a moist vapor.

Intubation, he went on to say, possessed every advantage possessed by tracheotomy. It could also save many cases in which tracheotomy would not be permitted, as well as many which would die if the latter were performed, especially in children under three years of age. Out of twelve cases in which Dr. Huber had resorted to tracheotomy, ten had proved fatal. He had also seen many cases in the hands of others in which the results were no more favorable, so that he felt warranted in assigning to intubation a much higher position.

DR. J. O'DWYER read a paper on "Feeding after Intubation of the Larynx," in connection with which he exhibited various tubes modified to overcome difficulty in feeding. He also showed specimens with the tube in position, and a section of the cricoid cartilage filled up with membranes, except where the tube had left an opening, the form of which was just the shape of the latter.

The difficulty of swallowing, he said, was recognized by all as the most important objection to intubation, and he had long been trying various modifications in the shape of the tube in order to diminish this as far as possible. At first he tried making the heads of the tubes quite small; but, while this rendered it possible for them to slip down into the trachea, it did not make deglutition any easier. The next modification that he made was to increase the size of the head to some extent, and also give the tube a greater curve, in

order to avoid ulceration at the base of the epiglottis. The third modification was to make the posterior surface of the tube longer than the anterior surface, so as to allow the epiglottis to pass over it more completely. Next, he increased the size of the head still further, so that it should fill the cavity of the larynx, and prevent fluid and other foreign substances from entering around it. The fifth modification was to make the upper surface of the tube concave, so that it would adapt itself more perfectly to the conformation of the parts, and this modification had the effect of rendering it very easy to remove the tube. With the pattern commonly used, extraction had always proved the most difficult part of the procedure.

The last modification which he had adopted was to give to the upper portion of the tube a double backward curve, in the hope of increasing the facility of swallowing, and this, at all events, had the effect of preventing ulceration of the anterior wall of the trachea, which hitherto had sometimes been quite extensive. Any one, however, who practised intubation at all largely would find it advisable to employ a variety of tubes according to the circumstances of particular cases; and he had lately devised a large, short tube for temporary use in certain instances. The string could be left attached to it, and he thought it probable, on account of the large calibre of the tube, that membranes might sometimes be coughed up through it.

Notwithstanding all his modifications, Dr. O'Dwyer said that he still found about the same difficulty in swallowing present. Solids and semi-solids, as a rule, were taken much better than liquids. Food would not enter the tube if the epiglottis was normal. In a number of instances he had removed the tube in order to give nourishment; but the results were no better than when it was in position. In some cases, particularly when nephritis was present, there was nausea and vomiting, as well as anorexia. Sometimes, however, swallowing was more readily accomplished than before the insertion of the tube, on account of the relief which it afforded to the urgent dyspnoea. As a rule, the longer the tube remained in position, the easier it became to swallow. When the patient was old enough to understand, he always gave instructions that drinking should be done rapidly, and that as large a quantity of fluid as possible should be taken at one time. Then, by coughing, the tube could be freed from any of it that might perchance have entered.

Sometimes he employed rectal alimentation, but he very seldom had to resort to the stomach-tube.

Passing on to speak of pneumonia, Dr. O'Dwyer said that in his opinion this might arise from (1) the presence of secretions in the lower air-passages; (2) an excess of blood drawn out of the lungs; (3) atelectasis (in the same cases in which there was an extension of the membranes); (4) the presence of a tube either in the larynx or the trachea. He did not believe that food was a cause of pneumonia, as there was no evidence that food had ever been found in the minute bronchi. He had known a patient (an adult female) to wear a tube in the larynx for over ten months, who not only did not have pneumonia, but who in the mean while recovered from bronchitis, which she had at the time the tube was put in.

He had lately had constructed two hard rubber tubes designed for all kinds of acute laryngeal stenosis in adults; the smaller one for women and young males, and the larger for full-sized males. The principal difference between these and the metallic tubes was in regard to their weight and the size of the calibre. While a rubber tube weighed only one hundred grains, an adult metallic tube weighed an ounce and three-quarters, and the rubber tube was fully double the calibre of the metallic. As regards the comparative comfort of the two kinds of tubes, one patient found the metallic tube the most satisfactory, while another, who was a syphilitic and had a very sensitive larynx, preferred the rubber. In the latter case the metallic tube produced ulceration, which was not the case with the rubber one, while greater freedom of movement and facility of expectoration were also secured with the latter.

DR. DILLON BROWN read a paper on "Statistical Records of Intubation." As far as he had been able to ascertain, there had been reported altogether seven hundred and sixty cases of intubation, by fifty-four different operators; and of these he had tabulated five hundred and two cases. Two hundred and eleven, or 27.07 per cent., had recovered. The average age of the children who died was three years and two months, and of those who recovered, four years and one month. In those who recovered, intubation was resorted to at an average period of two days and nine hours after symptoms of laryngeal stenosis had first appeared, and in those who died, at an average period of one day and nineteen hours. In the fatal cases the average time

between intubation and death was two days and eight hours; and in those which recovered the average time during which the tube was worn was five days and three and one-half hours. The causes of death he found were given in three hundred and thirty-nine of the fatal cases. Those who had performed intubation in the largest number of cases were O'Dwyer, seventy-eight cases; Waxham, one hundred and six cases; Dillon Brown, eighty-four cases; and Huber, forty-seven cases.

Unavoidable accidents, Dr. Brown went on to say, were rare, and, with the exception of the one of pushing the membranes before the tube, were not important. From the use of too much force false passages had been made in two instances. The slipping of the tube down into the trachea, which had been reported in several cases, could never occur if a tube of proper size was employed. In two cases the tube had passed into the œsophagus, instead of the larynx; but there was no reason why this mistake should be made if sufficient care were taken. In order to avoid as far as possible the danger of pushing membranes before the tube, he advised that the latter should be pressed well down, and held firmly in position with the finger until the obturator had been removed. Coughing up of the tube was a source of danger, but this could, as a rule, be avoided if a tube with a sufficient retaining swell was used. If there were paralysis of the muscles, however, this accident was liable to occur, notwithstanding an ample retaining swell. As to the causes of death after intubation, the extension of the membranes to the bronchi was the most frequent, and he believed that pneumonia, when present, was secondary in character.

DR. W. P. NORTHRUP read a paper on the "Pathological Anatomy of the Respiratory Tract after Death from Laryngeal Diphtheria and Intubation." In a paper on this subject, which he read before the Academy in December last, Dr. Northrup said that he had reported eighty-seven fatal cases. Since that time twenty additional fatal cases had occurred at the Foundling Asylum, so that he had now altogether one hundred and seven cases on record. The cause for this large number during so short a period as four months was the occurrence of diphtheria in connection with a fatal epidemic of measles and scarlet fever. The severity of the outbreak was shown by the fact that all the fatal cases had pneumonia, and thirteen of them nephritis. In his former paper he had stated that he had never met with ulcers of the

trachea; but in the twenty cases now reported for the first time there were deep ulcers, laying bare the rings of the trachea, in no less than five instances, and he presented the specimens from these cases. He had not as yet met with ulceration of any consequence caused by the head of the tube,—nothing more, in fact, than necrosis of the epithelium. He had never seen any evidence of aspiration pneumonia, as it was called, due to the entrance of milk or other fluid into the finer bronchi.

DR. IRVIN H. HANCE read the report of a "Case of Laryngotomy after Intubation." It was met with at the Nursery and Child's Hospital, and the patient, who was twenty months old, and suffering from scarlet fever and diphtheria, twice coughed up the tube. After it had been introduced a third time the tube became obstructed, and had to be removed. At this time the child was so exhausted that artificial respiration had to be resorted to for a while. The tube was then inserted for the fourth time, and again it filled up with mucus, and had to be withdrawn. After being introduced a fifth time it again became occluded, and was finally coughed up. The stenosis still continuing, laryngotomy was performed, at the crico thyroid membrane, and complete relief from the dyspnœa was at once afforded. The child died the next day, however, of the scarlatinous disease.

In this case, he said, the tubes were thoroughly tried, and were found to be utterly valueless. Their failure, he thought, was probably due either to the large quantity of tenacious mucus present or to the dislodgement of diphtheritic membrane. It was a question whether tracheotomy should not have been resorted to earlier, before the child had become so exhausted by the existing condition and the repeated introduction of the tube.

In conclusion, Dr. Hance alluded to other cases in which laryngotomy or tracheotomy had to be performed after a trial of intubation. Nine such cases, including his own, had been reported, and among these there had been three deaths and five recoveries, while in one instance the child was still under treatment at the time the report was made. The operation had been performed or advised under the following circumstances: 1. Great irritability of the larynx. 2. When membranes are pushed down before the tube. 3. When the tube became plugged up with dislodged membrane. 4. When there was a return of the dyspnœa with absence of the

tube from the larynx. 5. When the tube became wedged in the larynx.

As to laryngeal spasm, he had found that this could usually be controlled with belladonna, nitre, and chloral. Practically, the only condition calling for tracheotomy was the obstruction of the tube by membranes, and this was a very rare occurrence. The attempt had been made to remove the membranes with forceps. Finally, he said that he would advise resorting to tracheotomy only after intubation had failed.

In reply to a question of the President, Dr. A. Jacobi, Dr. O'Dwyer stated that in his later cases he had performed tracheotomy after intubation in only one instance. His own experience had been so unfavorable in this operation that he was not disposed to hope for much from it. As to removing membranes with the forceps, the subglottic division of the tube was of such narrow calibre that it was practically impossible to use this instrument, and he had, therefore, devised a flexible apparatus for this purpose somewhat on the principle of the umbrella probang. He knew of no wedging in the larynx that could occur except such as was sometimes met with when a tube with a very small head was used. Like Dr. Northrup, he had never seen any evidence of the so-called aspiration pneumonia arising from the entrance of food into the bronchi. The secretions, he believed, were the source of the pneumonia that was found after intubation, there being aspiration of these into the finer bronchial tubes. It was due primarily, however, to the presence of the tube, because the latter impaired the patient's power of expulsion, the secretions under these circumstances not being gotten rid of with the same facility as through the normal larynx.

The President said that he was much pleased to hear both Drs. O'Dwyer and Northrup say that they had never seen any reason to believe that pneumonia originated from the presence of food. He would like to inquire of Dr. Northrup whether lobar pneumonia was of frequent occurrence, and if so, whether this was found especially in cases of sepsis.

Dr. Northrup replied that in the eighty-seven cases previously reported by him, twenty-seven were believed to have died from extension of the diphtheritic membrane. In a large proportion of these there were found membranes extending from the tip of the nose to the finest bronchi of the lungs. Bronchial diphtheria, with œdema, was a marked feature at

the autopsies. Pneumonia, when it did occur, was of late origination. It affected both lungs, and was lobular, not lobar, in character. In not more than one-fourth of the cases could it be said to have been the cause of death.

Dr. Caille said that it was too early as yet to speak a final word as to the merits of intubation. Many of the cases published had been reported in such a way as to render them of no practical value. In comparing this procedure with tracheotomy in his own experience, he found that he had performed tracheotomy in twenty-one cases, with five recoveries, and intubation in sixteen cases, with six recoveries. In his cases of intubation, diphtheritic membranes were observed on the nares or pharynx in nine instances. Most of the cases were seen in consultation, and, as a rule, intubation was undertaken rather late. He believed that all the patients would have died without surgical interference, and that one who died would have recovered if intubation could have been practised earlier. The cause of death after intubation he had found to be catarrhal pneumonia in a majority of his fatal cases. It was a fact that most of the children who died had taken liquids, and of late he had allowed only solids, cut up fine with rice to allay thirst. Since he had adopted this course his results had been better.

In conclusion, he said that intubation was to be preferred to tracheotomy in the majority of instances. When the pharynx and nares are affected, intubation is preferable, as a rule, to tracheotomy, especially when the after-treatment of the latter cannot be carried out satisfactorily. Tracheotomy is preferable to intubation in some cases, hopeless without operation, provided the surgeon can operate and carry out the after-treatment under the most favorable conditions. These statements apply to intubation with the present style of tubes.

The subject may be concluded by the following summary of the present status of intubation published by Dr. E. Fletcher Ingalls in a recent number of the *New York Medical Journal*:

1. Intubation may be quickly and easily performed, and with but little danger.
2. Friends readily consent to the procedure.
3. There is no necessity of tedious after-treatment, as the tube is kept clear by the respiratory efforts.
4. The results so far are practically as good as those of tracheotomy at all ages, and apparently better in very young children.

5. To secure the best results, great care must be taken to prevent the entrance of foreign substances into the trachea.

6. At present, with O'Dwyer's tubes, the most successful plan is to absolutely prohibit the deglutition of fluids while the tube remains in the larynx. Small bits of ice may be sucked to allay thirst; soft solids may be swallowed, and fluids may, if necessary, be supplied by enemata, or the tube may be removed to feed the patient, and then be re-introduced.

7. Tubes with smaller heads, designed to rest on the vocal cords, have not yet been used sufficiently often to enable us to speak positively about them. If experience proves that they do not often slip into the trachea, and that they do not injure the vocal cords, they will be especially useful, for they will nearly overcome the difficulty in deglutition, and patients wearing them may eat and drink at pleasure, excepting when paralysis or some other result of the disease prevents closure of the epiglottis.

8. Medical treatment should be carefully attended to after intubation, and we must spare no effort to prevent extension of the disease to the bronchial tubes, or to relieve the dyspnoea which it occasions. Dr. Ingals apprehends that successful after-treatment depends largely upon the judicious and timely use of suitable expectorants and respiratory and cardiac stimulants.

9. Though short tubes may be used with good results in some cases, the danger of their becoming filled with pseudo-membrane is so great as to render long tubes preferable.

10. Intubation may and should be practised early, and it does not preclude subsequent tracheotomy.

11. For serious cases of spasmodic croup, and for œdema of the glottis, this will prove a most useful procedure.

12. For the treatment of chronic laryngeal stenosis this method will, doubtless, be of value.

NEURALGIA OF THE FIFTH NERVE.

At a recent meeting of the Odontological Society of Great Britain, PROF. VICTOR HORSLEY, F.R.S., read a paper on the "Pathology of Invertebrate Neuralgia of the Fifth Nerve" (*British Medical Journal*, July 23, 1887). He first gave a short history of three cases of this distressing malady which he had treated with apparent success by avulsion of the nerve. Two of the patients were shown at the meet-

ing. All of them had come under his observation at a very late stage of the affection, the shortest period being three years and a half after the onset of the mischief, and in one case as much as seven years after. All were practically edentulous when they came to him, and from all of them after the operation he had heard the same story, namely, gratification at being relieved from pain, and regret at the loss of so many sound and useful teeth. Were there, then, no indications by which it was possible to diagnosticate pain which was due to mischief somewhere along the trunk of the nerve from that which was due to disease of the teeth? If that could be done with any degree of certainty, it would mark a very important advance in dealing with these painful and often troublesome cases, and it was with the hope of obtaining some help from the members of the Odontological Society in deciding this question that he had brought the subject before the society. Pain referred to one of the branches of the fifth nerve might be due to mischief of cerebral origin, to irritation somewhere along the trunk of the nerve, or at its peripheral extremity. It was scarcely necessary to dwell on the possibility of the pain being due to intra-cranial mischief, since the general rules applicable to this class of cases would generally suffice for the discovery of the seat of the trouble. The diagnosis between some affections of the trunk of the nerve and of its peripheral termination was not so easy; but, judging from his own experience, he thought there were points which might assist in forming a decision. Trophic changes, when present, were a very valuable indication of mischief in the trunk of the nerve. Thus, in one of his cases, the lower lip was greatly swollen, the skin being glazed and excessively sensitive, or the vessels might be at one time dilated, and at another just the opposite. Wasting of the muscles was another evidence of the same kind. Certain abnormal conditions of sensation were also valuable. In an ordinary case of toothache all the branches of the fifth nerve might seem to be affected; but in cases where the disease was in the trunk of the nerve, the skin might be hyperæsthetic at one place and anæsthetic at another. Another characteristic form of hyperæsthesia was that in which gently touching the skin caused extreme pain, whilst firm pressure caused no pain at all. As to the apparent origin of the pain, he found that in most cases the patient said it began in the teeth, but in some cases it was said to begin in the bone or in the skin. If the pain was

primarily referred to the teeth, it might be due to them or it might not; but if it began in the bone or skin, and only affected the teeth subsequently, he thought it might be inferred that the disease was in the trunk of the nerve. If, in addition to severe pain over the area of distribution of the nerve, distinctly tender spots were met with along the course of its branches, this was generally an indication that the whole nerve was in a state of irritation, but a somewhat similar condition might sometimes be met with as the result of peripheral irritation. If the pain was brought on most commonly by movement, this seemed to indicate affection of the nerve-trunk. All his patients stated that opening the jaw to eat or to talk brought on pain, and, so far as he was aware, the effect of movement in causing pain was not so marked in cases where this was due to peripheral irritation. With regard to the treatment of these cases, of course any sources of dental irritation should be removed, and in some this would effect a cure. He had found that drugs invariably failed sooner or later. He thought that experience had made it clear that nerve-stretching, though a satisfactory operation as regards some nerves, should not be performed on the fifth; although it gave relief for a time, the pain invariably recurred. Avulsion, on the other hand, performed as close to the aperture of exit from the skull as possible, generally cured, the success of the operation seeming to depend greatly on success in obtaining primary union; nor was the removal of the nerve followed by any trophic changes in the parts supplied by it. A discussion followed.

THE MECHANISM OF THE THIRD STAGE OF LABOR.

At a recent meeting of the Obstetrical Society of London, DR. FRANCIS H. CHAMPNEYS dealt with Part 4 of this subject under the heading "Some Causes of Retention of the Membranes" (*The Lancet*, July 16, 1887). Having referred to the description of the process given in a former paper, the author showed that the "plane of least resistance" for separation of the membranes is in the decidua, generally in the ampullary layer. Any change which renders this more tough, or which renders any other layer more friable, will alter this "plane of least resistance." Thus, undue friability of the chorion, or less firm adhesion between chorion and amnion than between the layers of the decidua, will determine a separation of the chorion and

amnion. The early separation of the lower pole of the ovum tends to guard against a common defect,—viz., failure of separation (retention) of the membranes round the os internum. Rupture of the membranes at the proper time is an essential part of the proper mechanism. The proper time is, in nature, when the os is about three to three and a half inches in diameter, and has a projection of three-quarters to one inch. Premature rupture will prejudice the separation of the lower pole of the ovum. Too late rupture tends to produce prolapse of the bag, which is usually accompanied by giving way of the chorion and advance of the amnion alone. Undue or relatively undue toughness and elasticity of the amnion are equivalent to a tardy escape of the waters. As regards the removal of the membranes by traction of the descending placenta, the author remarked that the membranes as a whole owe their tenacity principally to the amnion; the adhesion of the amnion to the chorion is no doubt one of the safeguards against retention of the chorion. Thus any disorder of the first process of the mechanism tending to separate the two ovuline membranes predisposes to retention of the chorion. An analysis of ninety cases bearing on the matter was given. The conclusions were: 1. That the mechanism of the detachment and expulsion of the membranes is a complex act in three stages. 2. Timely rupture of the bag of membranes is an essential part of the proper mechanism, and too early or too late rupture alike predispose to retention of the chorion. 3. Disorder of any of the three stages in the mechanism tends to prejudice the whole process. 4. Among allied conditions may be mentioned too early or too late rupture of the membranes, prolapse of the bag of membranes, prolapse of the membranes (amnion) after delivery beyond the vulva; separation of the membranes found on examination of the placenta; retention of a ring of membranes round the lower pole of the uterus; retention of the whole chorion. The practical conclusions were: 1. The membranes should generally be preserved till the os is fully dilated. 2. After this they are not only (in ordinary cases) useless, but they—that is, the persistence of the amnion—favor the retention of the membranes. 3. They should, therefore, be ruptured when the os is fully dilated. 4. In vertex cases, if the head has settled over the os uteri, the advance of a smooth, sausage-shaped protrusion of membrane points to advance of the amnion alone, which favors retention of the chorion.

5. Separation of two membranes not only points to adhesion of the chorion, but renders its subsequent removal more difficult. 6. This axiom may be formulated : "When the membranes advance low in a vertex case, look out for retention of the chorion."

LITHIUM CARBONATE AND SODIUM ARSENATE IN CARBONIC ACID WATER IN THE TREATMENT OF DIABETES MELLITUS.

At a recent meeting of the Therapeutical Society of Paris, Dr. Martineau made a brief communication, in which he stated that for several years he had treated cases of diabetes mellitus with a solution of lithium carbonate and sodium arseniate in ordinary carbonic acid water, to the exclusion of every other medicinal remedy, and with a moderately strict antidiabetic diet. Dr. Martineau claimed that he had cured sixty-seven out of seventy cases of arthritic diabetes by this method of treatment, which he had borrowed from a practitioner now dead, the late Prof. Rouget, of Paris. The communication was discussed by Dr. Dujardin-Beaumetz and others, who regarded the method as so simple and, to say the least, innocuous that it was worthy of trial.

The preparation recommended by Dr. Martineau was the following. Into an apparatus such as is commonly used in Paris for extemporaneously making carbonic acid water, are put twenty centigrammes of lithium carbonate and a tablespoonful of a solution of twenty centigrammes of sodium arseniate in five hundred grammes of distilled water. The quantity of carbonic acid water used is about one litre. This quantity is to be drunk by the patient during each day, either by itself or mixed with ordinary wine at meals.

The simplicity of this remedy led Dr. AUSTIN FLINT to test its efficacy in certain cases of obstinate diabetes which he had under treatment, and he published his results in the *Medical News* for July 9, 1887. The ten cases reported led Dr. Flint to the following conclusions :

1. In the three severe cases in which the solution of lithium carbonate and sodium arseniate in carbonic acid water were used, no very marked effects were observed in the few weeks during which the remedy was employed ; but the treatment seems to be worthy of more extended trial, and it may be useful in mitigating the severity of a strict antidiabetic diet.

2. The so-called specifics for diabetes have little if any effect. An exception, however, may be made in favor of the arsenite of bromine, which has sometimes seemed to control, to a slight extent, the thirst, polyuria, and discharge of sugar.

3. The main reliance in treatment is to be placed upon an antidiabetic diet. This has fallen somewhat into disrepute because it is seldom efficiently carried out. In no single instance, out of ninety-nine recorded cases, did Dr. Flint find that the antidiabetic diet had been enforced.

4. Milk should be absolutely interdicted. Its influence over the progress of the disease is prompt, powerful, and most injurious.

5. There are certain cases in which dietetic treatment promptly arrests the disease and keeps it under control. There are other cases in which treatment seems to be of little avail, except in possibly retarding the progress towards a fatal result. Of the ten cases reported, and now under observation, seven are amenable to treatment and three are obstinate.

6. A confirmed diabetic may be cured, in the sense that all symptoms will disappear ; but the disease is liable to return at any time under an unrestricted diet. Still, moderate care in diet will often secure immunity.

7. A patient who has once had diabetes should have his urine examined every few weeks. The glycosuria always precedes the general symptoms of the disease, and these general symptoms can generally be forestalled by proper treatment employed as soon as sugar makes its appearance in the urine.

8. As the disease returns, either from imprudences in diet or from other causes, the successive recurrences present greater and greater difficulties in the way of treatment.

CANNABIS INDICA IN DIARRHŒA.

In a preceding issue we referred to the recommendation by Dr. Rennie in the *Indian Medical Gazette* of the employment of cannabis indica in the treatment of dysentery. In the *Practitioner* for July, 1887, Dr. FREDERICK F. BOND and Mr. B. E. EDWARDS call attention to the value of this treatment in summer diarrhœa. Attention was first turned to this use of cannabis indica by Dr. Turner in 1866, who employed the following prescription :

R Tincturæ cannabis indicæ, ℥x;
Spiritus chloroformi, ℥x;
Tincturæ kino, ℥i;
Aquæ menthæ piperitæ, ad ℥i.

The authors state that they have been in the habit of prescribing the above formula combined with small doses of morphine with marked benefit in nearly all forms of diarrhœa, the effects being most striking in the summer diarrhœa, in which affection the great depression, the frequent watery stools, the vomiting and cramp-like pains are quickly relieved, the appetite speedily returns, and cure is usually effected by the second or third day. They recommend the following combination :

R Tr. cannabis indicæ, ℥x;
Liq. morph., ℥v vel ℥x;
Spts. ammon. aromat., ℥xx;
Spts. chloroformi, ℥xx;
Aquæ, ad ℥i.

To be repeated every one, two, or three hours according to circumstances. Directions.—*No food for several hours, but a little brandy and water.*

It appears to act by increasing the astringent and anodyne properties of the morphine (the dose of morphine would have very little effect alone), by its stimulant effect on the nervous system, improving the tone, and by improving the appetite, enabling the system to quickly overcome the marked depression and exhaustion. Most remedies in this disease rather retard the return of the digestive functions, but from our experience Indian hemp markedly accelerates it. Indian hemp seems also to frequently counteract the bilious action of morphine, as well as the loss of appetite, and allows it to be given where it otherwise would not be tolerated.

In other forms of gastro-intestinal disturbance it is also valuable, probably for the same reasons. It was of marked use in a case of subacute gastro-enteritis, which had existed for a few weeks before it came under the author's care, in a girl aged 13 years, showing the following symptoms: marked anæmia, which had gradually come on after the other symptoms; constant pain over the abdomen, especially in the epigastric region, increased on pressure and after food; tongue covered with yellowish-white fur; loss of appetite; vomiting at variable times after food of partly digested material; diarrhœa, six or eight stools in the day, which were watery and green, containing partly digested food-material; some rise in temperature,—a little over 100° F. She was first treated with bis-

muth, then with effervescing mixtures, with no benefit; then with the cannabis mixture (modified to suit her age), and the symptoms very quickly subsided, the vomiting and diarrhœa were checked, the pain ceased, and the appetite returned. By the end of the week all the symptoms had disappeared except the anæmia, which persisted for a short time longer.

THE CREASOTE TREATMENT OF PULMONARY TUBERCULOSIS.

SOMMERBRODT, of Breslau, is quoted by the *Medicinische Chirurgische Rundschau* for June, 1887, as reporting five thousand cases of pulmonary tuberculosis treated by creasote. His studies have extended over nine years in time, and the patients so treated were all ambulatory cases. By the use of Bouchard and Gimbert's formulæ he treated a number of patients, twenty-seven per cent. of whom recovered. The formulæ most used were 13.5 parts creasote to 1 quart alcohol or Malaga wine; also 2 parts of creasote to 150 of ol. morrhue. Of both of these preparations from 3 to 6 minims of creasote were taken daily. He also used the following :

Creasote, 3.5 parts;
Alcohol,
Aquæ, aa 125 parts.

Of which a teaspoonful was taken twice daily in a glass of water by thirty patients. Following the method of Reuss, the best results were given by the following: Gelatin-capsules, containing each $\frac{3}{4}$ minim of creasote and 3 minims of balsam of tolu. The first day of treatment the patient took one of these capsules, on the second day two, and then for eight days three were taken, after meals, with water. In the second week four capsules daily were taken, in the third five capsules daily, and in the fourth week six capsules daily, always after the principal meals of the day. The remedy, when so given, was generally well borne; they were rarely taken except at meals; their use was continued frequently for a year, and was combined with treatment in favorable climates. The best results were obtained in young patients, in the first stages of the disease, with ill-defined symptoms. In scrofulous gland-affections the results obtained were also good. The irritation and frequent cough present were generally relieved, so that narcotics could be discontinued; bronchial secretion and night-sweats lessened. Sommerbrodt believes that many

such cases can be greatly improved. The remedy must be used for three months or a year, and the more that can be taken the better the results.

MELON-ROOT AS AN EMETIC.

Heberger in describing (*Repertoire de Pharmacie*) the bitter principle of the Cucurbitaceæ attributed emetic and purgative properties to melon-root. Torosicvitz (*Bolletino Farmaceutico*) has found that the emetic principle is a bitter substance extractable by alcohol from the aqueous extract of melon-root, which he designates melon emetine. It occurs in compact brownish masses, breaking with a shining fracture. It is very deliquescent. The aqueous solution has a piquant, bitter taste. It does not react with alkalis or acids, and colors ether. It quickly dissolves in alcohol, but is readily precipitated therefrom by lead acetate or infusion of galls. Liquor ammonia and liquor potassæ dissolve it readily, and from the resulting solution a brownish-gray precipitate is thrown down on addition of acid, which is rather insoluble in water. Recent experiments show that 9 centigrammes of melon emetine produce vomiting. Dr. Langewicz states that the wild plants contain more melon emetine than the cultivated.—*Western Druggist*, July, 1887.

TREATMENT OF PHTHISIS WITH INHALATIONS OF HYDROFLUORIC ACID.

SEIDER, of Paris, has applied this treatment by impregnating the air of the room of phthisical patients with spray, driven by a rubber balloon, and obtained from a solution of 3 parts water to 1 part hydrofluoric acid. The inhalations were made daily for twenty to thirty days in succession. They were at once followed by a relief of the oppression and dyspnoea; the cough was a little more frequent, the night-sweats lessened, and sleep returned. The expectoration was lessened, appetite and body weight increased; an improvement was plainly discernible.—*Medicinishe Chirurgische Rundschau*, June, 1887.

GYMNEMIC ACID.

Gymnemic acid is an organic acid, discovered by Hooper and described before the Nilgire Natural History Society (*Nature*), present to the extent of about six per cent. in the leaves of *Gymnema sylvestre*, a plant in-

digenous to East Africa and in the East Indies adjacent to Bombay. It resembles crysophanic acid, but has the peculiar property of destroying the sweet taste of sugar and saccharine liquids, as also the bitter taste of substances like quinine. It is extracted from the leaves by water and precipitated by sulphuric acid, being in combination with a base not yet investigated. Its employment for pharmaceutical purposes, however, must remain speculative until its therapeutic properties are further investigated.—*Western Druggist*, July, 1887.

The powdered root has for a long time been used among the Hindus for snake-bites. It is applied locally and taken in the form of a decoction internally. The most curious property of this plant is its effect upon the sense of taste. When the leaves are chewed, all power to appreciate the taste of sugar ceases. Powdered sugar tastes like so much sand. When an insufficient quantity of the leaves are chewed the sugar has a saltish taste. In gingerbread the taste of the sugar disappears and that of the ginger alone is detected. A sweet orange tastes like a lime. Sulphate of quinine tastes like so much chalk. The effect seems to last for several hours. The active principle of the leaves Mr. Hooper calls gymnemic acid. It does not affect the power of tasting sour, saline, or astringent substances.—*Albany Medical Annals*.

THE EFFECT OF HYOSCINE HYDROCHLORATE.

KOEBER, of Dorpat, Russia, is quoted as follows by *Schmidt's Jahrbuch*, 1887, No. 6, in the results of his use of this drug as a sedative:

Hyoscine, when given in large doses, is excreted as such by the kidneys. A small amount of the urine of an animal thoroughly under the influence of hyoscine, when dropped upon the heart of a frog which had been poisoned by muscarine, will cause the heart which was quiescent to beat. Hyoscine is thus an antidote to muscarine. In the same way, muscarine, by its stimulant power over the pneumogastric, will cause a heart to beat which had been stopped by hyoscine. The effect of the drug is the same upon the human subject as upon the frog. In the case of a patient with melancholia, whose pulse was slow, an injection of $\frac{1}{16}$ of a grain produced a very perceptible acceleration. In small doses, of $\frac{1}{16}$ to $\frac{1}{8}$ of a grain, hyoscine is a weak narcotic to healthy human beings.

Numerous observations made upon the large numbers of patients at the Dorpat Clinics for Insane Patients have proved its excellence as a reliable hypnotic, when given subcutaneously in doses of $\frac{1}{10}$ to $\frac{1}{8}$ of a grain of the hydrochlorate. A peculiarity of the use of hyoscine was the absence in the cases noted of all ill after-effects produced by the drug.

THE ADMINISTRATION OF OPIUM.

There are few drugs more commonly prescribed than opium, and it is certain there is none more abused or more carelessly combined. Of its numerous official preparations it cannot be said that their individual actions are free from the disagreeable after-effects which characterize that of the pure drug. The problem is to get all the good effects of the drug, and yet to obviate the resulting headache, sickness, and loss of appetite caused by arrestment of the secretions of the alimentary canal. This, of course, refers to medium doses. Belladonna or atropine have for long been given in combination with opium, but in these respects the result has been mostly a failure, the reason being that while the actions of these drugs on the central nervous system are to a certain extent antagonistic, their actions on the alimentary secretions are much the same. For some time Dr. A. G. AULD (*Lancet*, July 16, 1887) has given opium in combination with ether with good results, ether being one of the most powerful secretion stimulants we know. He generally prescribes equal quantities of tincture of opium and spirit of ether, and though not claiming for this a specific effect, thinks it a good and most useful mixture.

A FORMULA FOR NAPHTHALIN IN PILL FORM.

BERNBECK has found that a pill covered with elastic collodion is especially useful in administering this drug. His formula is as follows:

R Naphthalini resublimat., 10 parts;
Rad. althæe pulv., 5 parts;
Mucil. gummi arab., q.s.
Ut. fiant pilul. 100.

Dry without heating, and cover with elastic collodion.
Sig.—Two or three pills three times daily.

The remedy is especially useful in gastrointestinal catarrh.

The advantage of the collodion coating is found in the fact that it is dissolved in the

intestine and not in the stomach, and that no unpleasant taste is experienced from gastric eructation. For the success of the collodion coating it is essential that the pills be carefully dried before its application.—*Deutsche-Amerikanische Apotheker-Zeitung*, June 15, 1887.

THE TREATMENT OF FRACTURES OF THE FEMUR.

DR. THIRIAR, in an instructive clinical lecture to the Brussels medical students on the treatment of fractures of the thigh, pointed out the advantages of the telescope apparatus proposed and described by Professor Dero-baix some seven years ago. This consists, firstly, of a starch bandage reaching from above the knee to the foot, provided with a stirrup and a cord, which passes over a pulley, and has a weight attached to the end in order to keep up constant extension; and, secondly, of a femoro-pelvic starch bandage, which is applied two or three days after the first bandage, the upper part of which it covers so that the one may slide within the other in telescope fashion. When dry, the femoral portion is slit up. It can thus be opened and the seat of the fracture inspected at pleasure, and, if necessary, manipulated by the hands, while an assistant makes any required degree of traction on the leg. Afterwards it can be tightened up by straps and buckles, with which it is provided, and the limb is then absolutely protected against all lateral or see-saw movements, while the patient can be moved as is necessary for purposes of cleanliness without endangering the rigidity of the fractured limb. By this means Dr. Thiriari believes better results can be obtained than by any other apparatus; and he publishes a list of thirty cases, in all but two of which there was either no shortening or so little that it did not amount to a quarter of an inch. In one of the two unsuccessful cases the patient was excessively unruly, and in the other no amount of manipulation appeared to reduce the deformity when first seen.—*The Lancet*, July 2, 1887.

VOLKMANN'S ANTISEPTIC LIQUID.

Thymol, 1 part;
Alcohol, 10 parts;
Glycerin, 20 parts;
Water, 100 parts.

The above, as used by the German surgeon whose name it bears, is a useful formula for antiseptics by thymol.—*Deutsche-Amerikanische Apotheker-Zeitung*, June 15, 1887.

*SALICIN IN THE TREATMENT OF
SCARLATINA.*

Salicylate of sodium and salicin have been highly recommended for the treatment of acute tonsillitis, when given early after a free purge, when the disease will with almost a certainty become arrested. If the tonsils have become swollen and hard, or if pus has formed, nothing, of course, will prove effectual, and the disease will run its course.

MR. W. P. MEHARRY writes to the *British Medical Journal*, July 2, that in scarlatina, especially in that known as scarlatina anginosa, salicin is of great value, and in those cases of simple scarlatina in which the disease is prolonged by the throat complication salicin immediately effects a cure.

Mr. Meharry generally gives to a child four or five years of age 5 grains of salicin every two hours until the temperature becomes normal. Afterwards the same quantity three times daily for a few days to prevent a relapse.

Reviews.

A TREATISE ON DIPHTHERIA HISTORICALLY AND PRACTICALLY CONSIDERED, INCLUDING CROUP, TRACHEOTOMY, AND INTUBATION. By A. Sanné, Docteur en Médecine, etc. Translated, annotated, and the surgical anatomy added. Illustrated with a full-paged colored lithograph and many wood engravings. By Henry Z. Gill, A.M., M.D., LL.D., etc.

St. Louis: J. H. Chambers & Co., 1887.

This is a very complete work upon diphtheria, leaving very little unsaid, and to which the surgeon as well as the practitioner can refer with the certainty of finding what he wants, if it is possible to find it anywhere.

Its leading chapter covers the ground of "Tracheotomy in Children." It is profusely illustrated with an excellent series of woodcuts, which are invaluable to the operator. The main portion of the book, devoted to diphtheria, embraces chapters on its localization, course, duration, and termination, recurrence, epidemics, nature, sequences, complications, prophylaxis, etc. In treatment the author views all specific lines of medication with cynicism. Tried by the cold glance of statistics they fail to do the wonders they promise. He does not believe in iron, in alkalies, in terebinthinate remedies; mercurials having been given, as he thinks, to diminish the fibrin in the blood, and the fibrin not being in excess, are, of course, absurdly useless, and, what is worse, dangerous. Support, restoration by food, alcohol, and local

disinfection may do some good. Tracheotomy should be early done. The attendant should not wait for obstruction.

Intubation is carefully and fairly treated. The author evidently considers it as a proved and established procedure of great value. Full directions are given for the operative work of intubation, and the chapter is carefully illustrated for the needs of the subject. The book is a thoughtful one, and contains a mass of valuable information.

E. W. W.

OUTLINES FOR THE MANAGEMENT OF DIET, OR THE REGULATION OF FOOD TO THE REQUIREMENTS OF HEALTH AND THE TREATMENT OF DISEASE. By Edward Tunis Bruen, Assistant Professor of Physical Diagnosis, University of Pennsylvania; one of the Physicians to the Philadelphia and University Hospitals; Lecturer on Pathology in the Woman's Medical College of Philadelphia, etc.

Philadelphia: J. B. Lippincott Company, 1887.

To know what to eat and when to eat it is better than the possession of any extant elixir of life. Such knowledge is one-half of hygiene and one-half of medical treatment. Starvation slays many and gluttony more, but a wise diet protects a man from far more dangers than he dreams of.

To know a subject well one should master its general principles. To order a proper diet for one's self or another, we should understand the physiology of digestion. This our author gives us briefly in his chapter on "Points on the Physiology of Digestion." Another important matter is the varying diet required for varying age. The diet for the infant must differ from that suited to the mature or the aged. How it differs and why, we learn in the chapter on "Regulation of Food to the Requirements of Health in Different Periods of Life."

In "Liquids Used as Beverages" the author studies tea, coffee, cocoa, and the much-disputed alcohol question. "Certainly in health," he says, "or in chronic diseases, its use is for the most part undesirable as a food." "In advancing life it can be guardedly used." The contamination of water, and the value of pure water as a beverage, are briefly but carefully discussed. The fundamental principles of infant feeding are well explained in the chapter on "Special Plans of Diet," which is followed by one on the "Amount of Food required by the System." Chapter vi. tells us how to grow fat or lean, as we happen to need the advice, and the remainder of the book is devoted to "Diet in Special Diseases," in which the seeker can find many valuable hints, many

ways perhaps unthought of, but here suggested, which may prove of more value to the sick than any amount of mere drugging. In fact, the book is well worth owning.

HANDBOOK OF PRACTICAL MEDICINE. By Dr. Hermann Eichhorst. Vol. III. and Vol. IV. New York: William Wood & Co., 1886.

Vol. III. of the series of volumes composing this handbook is devoted to diseases of the nerves, muscles, and skin, Vol. IV. to diseases of the blood and nutrition, and infectious diseases. Throughout both volumes the student will recognize the same minute handling of all subjects which gives the work its great value. The chapters on diseases of the nervous system and muscles, especially, are profusely and excellently illustrated. Vol. IV. is, perhaps, more likely to interest the average professional reader. The section on diseases of nutrition opens with a chapter on "Obesity," which, in terse language, sums up the most recent views on this subject. The chapter "Diabetes Mellitus" is quite elaborate and gloomy, the author considering all remedies, apart from rigid diet, as of very uncertain efficacy. He makes no mention of the arsenite of bromine, and while doubting the value of opium in large doses, remarks that the reports concerning arsenic are "less favorable than those concerning opium." Duhring's claim to have cured a number of cases by pursuing a certain dietetic regimen he regards with derision. For salicylic and carbolic acids, as recommended by Ebstein and Mueller, he says, "We must experiment with these remedies, since different patients react differently," which will be taken by some as but one more instance of the German scientific method of regarding patients as only so many chemical combinations. In the chapter on "Rickets" the author advises lime-water, more animal food, fresh air, without urging the child to walk, cod-liver oil, and a bath of salt water.

Regarding scarlet fever, we find that the author endorses the view that the diphtheritic complications of the disease are manifestations of true diphtheria, for which scarlet fever "creates a predisposition," though the different clinical behavior of the scarlatinal from the ordinary diphtheritic membrane is noticed. With the exception of lukewarm baths, the author makes no special recommendation in treatment.

Rötheln, which the author uses as synonymous with rubeola, the author considers as

a distinct infectious disease independent of measles or roseola. The diagnosis from measles, scarlatina, and roseola "is not always possible." For erysipelas the best local application, in the author's opinion, is carbolic acid dissolved in turpentine, 3ss to ʒi of the latter, applied every hour. When gangrene occurs the parts should be dressed with acetate of alumina, one or two per cent. solution. The only internal remedy mentioned besides enemata of antipyrin is potassium iodide, gr. vii, every two hours.

The author gives herpes of the pharynx and larynx a definite description, which could be read with profit by several recent writers. He has found the vesicles in one case by the laryngoscope on the posterior surface of the uvula.

Under the caption of "Sweating Sickness" he describes miliary fever, directly tracing it back to the historic epidemics of the disease from the fifteenth century. It appears in epidemics, generally in summer, and is "an independent infectious disease." Under the subject of vaccination the author has written a very valuable chapter. The author advocates humanized virus, makes light of any danger, if properly selected, and considers that by the use of bovine virus, among other dangers, there is incurred a considerable one,—of the introduction of tubercle. All animals from whom lymph is taken for human use should be killed and examined carefully. When vaccination is followed by the appearance of "pock-like vesicles over the entire body" it is due to "accidental combination with varicella." In the chapter on "Cholera" the author expresses his belief in quarantine of the strictest character. In the treatment of this disease he recommends rest, very little food, weak broth, and a combination of ipecac and calomel every three hours. Venereal disease and tubercle and diphtheria occupy the remaining portion of Vol. IV. Taken as a whole, the "Handbook of Practical Medicine" is a work of great value, and the publishers are to be especially commended for placing it in its accessible and cheap form before the medical public.

E. W. W.

A MANUAL OF WEIGHTS AND MEASURES, WITH RULES AND TABLES. By Oscar Oldberg, Pharm.D. Second Edition.

Chicago: Charles Johnson, 1887.

A knowledge of the metric system is becoming every day more and more essential to enable one to keep abreast with the progress of medical science. A great proportion of

recent discoveries first appear in continental literature, where, it is needless to say, the metric system is now solely employed. In the majority of abstracts of foreign papers, on which physicians who, unfortunately, are ignorant of French and German are compelled to rely, as a rule, the metric system is reproduced. In the *GAZETTE* we make it a point to transpose the quantities from the metric to apothecary's measure, giving the figures in both systems, but it is evident that such translations of the metric system can only be approximate unless we run into complex fractions, and sometimes these translations may be overlooked. We have, in the columns of the *GAZETTE*, several times furnished our readers with tables for the convenient conversion of the different systems of weights and measures, but for an extension of the subject we would refer to Dr. Oldberg's book.

Dr. Oldberg's treatise on metrology includes in a compact space everything pertaining to the subject which can be of necessity. It contains the elements of metrology; the relations between metrological systems and arithmetical notation; a brief review of the development of weights and measures; the demands of practical medicine and pharmacy in the matter of subdivision of the units employed; the metric system; American and English weights and measures; the relations of weight to volume; specific weight; specific volume; the construction, use, and preservation of balances or scales, weights and measures, and of alcoholometers, urinometers, and other hydrometers; and extensive tables of equivalents; while the application of weights and measures to prescribing and dispensing, and to the construction of formulæ for liquid preparations, have received merited careful attention.

Correspondence.

LONDON.

(From our Special Correspondent.)

We are now enjoying one of the most beautiful summers we have had for years in England. Nothing in the way of weather could have been more fortunate, for we have resigned ourselves during the past fortnight to the delights in connection with the jubilee of our gracious queen. Summer in England is a season when visitors, whom we have in such numbers at present, may study this

people with profit. The Anglo-Saxon race gives full play to some of its leading characteristics in the lovely evenings of June and July. From the youngest to the oldest all are out of doors and enjoying themselves in the thoroughly national or racial fashion of taking laborious exercise. Every village green is at this moment covered with cricketers; every lawn is the scene of an earnest contest at tennis. I often ask myself what our neighbors across the Channel think of all this. I know how amazed Orientals are to see our brothers in India and China taking violent exercise in the sun as the most enjoyable of pleasures. I wonder how far our friends on the other side of the Atlantic yield to the same manly enticements. And all this is often before my mind, because I cannot help connecting the health of our English people, and their position on the earth, with their undying love for robust sports. Nothing seems too much for our boys in the way of muscular expenditure. Thousands—very likely tens of thousands—of bicycles and tricycles must carry their riders out of London every Sunday. Thousands of us spend Sunday on the Thames,—anywhere within fifty miles of the metropolis. I can imagine that when you read of our regattas and cricket-matches you may conclude that our boys take to the same forms of amusement to copy their seniors. The order is just the reverse: our famous oars- and batsmen have grown out of youngsters who took to boating and cricket with their companions as soon as they were breeched! These are our national games and occupations. A master who cannot play cricket creditably stands a poor chance of election to a post in a public school, however distinguished he may be as a scholar or mathematician.

Now it appears to me that all this has a more than ethnical interest to us: it bears upon the pathology and the therapeutics of the diseases which we, as medical men, are called upon to study and to treat. We hear very much at the present time of change in the type of disease. We are told that disease is now less "sthenic" and more "neurotic;" that nervous disorder is greatly on the increase, and that even in nervous disorder the type is changing,—that lunatics are now mainly melancholic and less often maniacal; that the maniacal cannot bear depressants, but recover under sustaining nutritive treatment. No doubt there is much truth in all this. No other result could well be expected to follow the change of thought, of labor,

and of surroundings wrought by the railway and the telegraph. But I believe our fears are greatly exaggerated. Whilst we have a lamentable number of break-downs in a nervous direction, the backbone of our population may be complacently regarded as healthy and of well-balanced constitution. Boys and girls, men and women alike, they show no sign to any eye of national degeneration. The feminine sex are in their way as active as their brethren. Tennis has been nothing less than a national blessing in the effect it has had in bringing women out of doors and keeping them active and happy for hours in the fresh air. A week ago a Scotch girl was Senior Classic at Cambridge,—for the first time in history a woman carrying off the highest classical instruction of the year. Do not interpret this event, if you please, to mean that our daughters are all taking to Greek and Latin. This week we are scanning with equal interest and excitement the report of the progress of the tennis tournament at Wimbledon, where ladies figure very largely. My belief is that whilst those of us who do suffer and break down may do so more in a neurotic direction than was the case fifty years ago, the actual number of the sick and the delicate is actually less. This is a fact about which I believe there can be no doubt; but it is a fact that appears to be overlooked by those who harp upon the decline of the English people. Its bearing is to be traced also in treatment. Nervine tonics are all very good in their way, but we are returning here to common sense and calomel, and getting better results than we got a few years ago from quinine and strychnine. Venesection and tartar emetic may never come again to be our sheet-anchors in fever, but we have lived to see it proved—though as yet not practically confessed—that our so-called nutritive system of treatment in typhoid, beef-tea and jellies, is little short of a system of starvation, and yet wonderfully successful.

Sir John Lubbock, whose name is familiar to your readers as at once a distinguished *savant* and politician, to whom the very class of whom I have been speaking—the young working population of our cities—owe their precious bank-holidays, has just been delighting us with his views on certain points connected with our profession. Improving the occasion of the distribution of prizes at Charing Cross Hospital last week, Sir John reminded his audience that medical treatment as now taught and practised is by no means so “natural” as most of us seem to

regard it. It is at first sight scarcely conceivable that there are other ways of treating disease than for the doctors to bring patients under the influence of well-understood natural forces, whether medicinal or non-medicinal. But in truth the very opposite method is practised in some parts of the earth, and probably was practised here and with you in earlier—indeed not very remote—times. Under this system the doctor swallows the physic, the patient not. The physic works upon the medicine-man and enables him to exorcise or otherwise combat the evil spirit that haunts or possesses the sufferer. As Sir John Lubbock wittily remarked, this system may be all very good in uncivilized countries, but it is not likely to commend itself as pleasant, practicable, or profitable to us who covet an extensive practice, and who might not recover with sufficient rapidity from the successive doses to sustain a popular reputation. Truly, from strange beginnings and by an interesting process of evolution has our present therapeutics been perfected.

I find the recent numbers of the *GAZETTE* furnished with valuable reports of M. Bergeon's treatment of phthisis as it is practised in the States. We hear less of the system with us than one might have expected, considering the prominence given to it at first. In England it must have been received with distrust, for it created no enthusiasm. As a matter of fact, I have been told more about the value of gaseous enemata by friends returning from the continental stations than I have learned from the staffs of our different hospitals for consumption. Very different have been the opinions thus expressed to me. In the Alps, at Davos, to wit, the results have been anything but encouraging, and the estimate of the value of the system given me a few weeks ago by one of the most distinguished practitioners of that place was decidedly unfavorable. *Per contra*, one of the best known English physicians on the Riviera assured me the other day that he had seen unquestionably good results from the Bergeon enemata. The sulphide of carbon, which I understand M. Bergeon now recommends, is said to be not altogether safe, and must not be employed in the somewhat casual routine fashion prescribed by some of our French *confrères*. It is evident there is but one way of settling this question,—by hard facts. I can see no *a priori* reason for the employment of sulphuretted hydrogen in phthisis,—certainly none for its administration *per rectum*, for we know nothing of the effect of

the liver upon hydrosulphuric acid conveyed to it in the portal blood,—an action on which M. Bergeon appears to have forgotten to reckon. The results of carefully observed cases ought to be the only argument admitted. As for the effects of this method on asthma, that is another matter,—a matter of treating a highly complex neurosis by a novel, startling method which is certain to have a temporary success.

In one of my letters to you I referred to Mr. Victor Horsley's operations on the brain, and mentioned a case of cerebellar tumor which had been removed,—unfortunately, without good result. I have now to chronicle an extension of the surgical treatment of disease of the central nervous system in a direction which was plainly indicated by all our recent knowledge in this province of pathology. A week or two ago Mr. Horsley removed a tumor from the spinal cord with complete success at the time, and, I trust, with ultimate relief of every symptom. We are now so well acquainted with the symptoms of tumor of the cord and its meninges, that there can be no doubt this operation will be speedily repeated, and, indeed, come to take its place among the legitimate and most successful of surgical procedures of the first magnitude.

Since the publication of my letter of June we have had the publication of the report of the committee on Pasteur's method of treatment for the prevention of hydrophobia, the principal points of which I correctly anticipated. The pronouncement of the committee in favor of M. Pasteur has been heartily welcomed by the English press, both lay and professional. Before many days are over I have little doubt but the government will be asked what practical use they intend to make of the finding of the committee,—a finding which, if it do not express a recommendation of the establishment of a Pasteurian institute in London, certainly suggests that our government ought to provide the means of immediate inoculation to the unfortunate victims of rabid animals much nearer home than Paris. Let us hope that the vaccination department of the Local Government Board may at once take this matter up and put the method into practice.

PARIS.

(From our Special Correspondent.)

Is alcohol incompatible with pepsin? is one of the many questions of therapeutics that has most divided chemists and practitioners,

and has caused the greatest divergence of opinion. The controversy is of perhaps fifteen years' standing, if not more, for some thirteen or fourteen years ago it was already discussed by Mr. Phillipp, before the Alumni Association of the New York College of Pharmacy. The Paris Société de Thérapeutique, an association including both physicians and pharmacists, recently gave the question another overhauling, the conclusion of which may fairly be said to be that alcohol is and is not incompatible with pepsin, according to circumstances. Dr. Bardet, Dr. Dujardin-Beaumetz's *chef de laboratoire* at the Cochin Hospital, led the discussion with an elaborate paper, well supported by experiments, and gave it as his opinion that up to twenty per cent. of alcohol is a proportion that pepsin solutions can stand with perfect impunity. Above twenty-five and up to seventy per cent. the loss of digestive power is in exact proportion with the excess of alcohol introduced. Above seventy per cent. the ferment is killed, just as albumen is suddenly coagulated at a certain temperature. This property explains the inertness observed by M. Catillon in specimens of pepsin precipitated by alcohol from glycerin or watery solutions. As to the loss occurring when wine is used as a solvent, it should be attributed to the tannin, not to the alcohol of the menstruum. M. Pierre Vigier partly agreed with Dr. Bardet, his own experiments having convinced him that eighteen or twenty per cent. of alcohol does not seriously impair the digestive ferment, although its power be somewhat injured. For this reason the revisers of the French Codex were right in admitting to the official list, notwithstanding Dr. Vulpian's opposition, wine and elixir of pepsin, two excellent preparations. But Dr. Bardet maintained his position; his experiments are conclusive, and prove that a proportion of alcohol not exceeding twenty per cent. has no untoward effect on pepsin, and it is only when twenty-five per cent. is reached that the ferment begins to be injured; the same result may be accidentally produced when alcohol is too rapidly added to solutions of pepsin, because then a portion of the digestive ferment may come into contact with a destructive proportion of alcohol.

French physiologists appear to concur in the opinion that strychnine is one of the poisons that patients do not become accustomed to. In other words, *one never gets used to strychnine*. It is true cases are on record in America in which considerable doses of the

alkaloid have been taken without harm, but these occurred with alcoholic persons, and therefore under peculiar physiological conditions. At a recent meeting of the Société de Biologie, Dr. Chouppe, after relating experiments on dogs, concluded that the economy never becomes habituated to strychnine. For instance, the same dose was administered for seventy-five days in succession, and always had exactly the same effects on the animal, while any slight increase of quantity in the mean time brought on grave accidents. Dr. Brown-Séquard entirely agreed with this opinion, a conclusion he had reached himself long before. A patient will take with impunity doses of strychnine very closely approximating the quantity sufficient to cause convulsions, or at least contractions. But once this point has been reached, the slightest possible increase of dose will be followed immediately by a general tetanic state. Hence we find neither an acquired habit nor accumulation accidents. He had also observed that strychnine is more rapidly absorbed on certain days than others, even when the precaution is taken to administer it after meals. Yet he thought French physicians are too timid by far in exhibiting strychnine, as it can be exceedingly useful in cases of organic paralysis, medullar affections, certain forms of chorea, etc., provided it be administered in nearly convulsivant doses. The two extremes to be avoided are, on one side, insufficiency, and, on the other, too rapid an increase of the beginning dose.

Acetanilide useless in Epilepsy.—When a new medicament is discovered it is often apt to be overestimated. For this reason, next to knowing what a substance is good for, perhaps the most important is to learn in which cases it is useless, or worse. Owing to its general therapeutic properties, Dr. Faure, of the Bicêtre Hospital, was led to administer acetanilide (antifebrin) for epilepsy, in Dr. Deny's service. The report which he has made is decidedly unfavorable. The patients, five in number, were treated for two months and a half, and carefully observed two months after the medication had been suspended. The medicine was given in increasing doses from 50 centigrammes to 2.50 grammes (8 to 40 grains). The patients while under treatment were affected with some of the symptoms already known, and more especially with cyanosis of the extremities and face, which would never fail to appear after two days, and rapidly disappear when acetanilide would be withheld. As regards therapeutic effects, they have been absolutely nil.

Far from improving, four of the patients out of the five experienced many more fits during the treatment than within the same time before. Three of the patients even had the number of fits almost doubled. It may be that some coincidence has affected the results, but it must be confessed they are really far from encouraging.

Medical Jurisprudence.—French courts hold that between a physician and his patients an implicit agreement exists respecting the fees, which cannot be changed without explicit notice. A recent case in which the jurisprudence was applied was as follows: Mme. L. was in the habit of being attended in her confinements by Dr. N., and every time one hundred francs (twenty dollars) was the fee paid and accepted. Lately, after requiring Dr. N.'s medical attendance under the same circumstances, she was served with a bill for forty dollars, which she refused to pay. Dr. N. had, it seems, risen in the world, and thought his services worth twice as much as before, while Mme. L. contended she had received no notice of the increase, and was not therefore liable to pay more than usual. The court of Paris gave a judgment in favor of the patient, affirming the well-settled principle that if a physician has a right to enhance his scale of fees whenever he sees fit, he should give notice of the fact to his regular patients, to enable them to either have his attendance on the new conditions or to call in another physician.

Morphinomania, the fashionable vice of the period, scarcely less baneful than the more popular alcoholic intoxication, may, perhaps, not attract much public notice. But it is a mania of much concern to the medical profession, the more so that they often feel they have been the cause, direct or indirect, of the morphine-habit contracted by their patient. Many are the cures suggested for the evil; some are probably good, still, prevention is better, and Dr. Germain Sée, acting with this end in view, in a paper read before the Academy of Sciences has frankly proposed *antipyrin as a substitute for morphine*, whenever the physician only wishes to allay pain, and expects nothing more from the usual therapeutic effects of the opium alkaloids. He gives antipyrin in hypodermic injections, half a gramme of the substance with half a gramme of water to fill a Pravaz syringe. The injection is administered in the same manner as morphine; and after a short period of unpleasant tension the pain, whatever may be its cause, is greatly relieved, without the

sleepiness and the artificial, pleasant excitement which frequently leads to the morphine-habit. Besides, antipyrin often possesses a curative effect lacking in morphine. Many cases of articular and muscular rheumatism, acute and chronic gout, neuralgia, zona, lumbago, etc., successfully treated with antipyrin were detailed by Dr. Sée; but as morphine would have not been contraindicated with such patients, the main advantage was that the physician would feel his medication had not led a fellow-being to become a morphinomaniac. In other complaints, however, morphine is distinctly harmful, and antipyrin should be substituted. With patients suffering from biliary calculi, for instance, the administration of morphine has, it is true, a sedative effect on hepatic colics, but it has also the inconvenience of decreasing biliary and intestinal secretions, thus interfering with the flow of matters, and supplying the occasion for more suffering. Antipyrin, on the contrary, rapidly stops the pain without causing any visceral disturbance. The same is true of nephritic colics; they are relieved, with the important advantage that the flow of urine is not decreased, while morphine, by suppressing the urinary secretion, is liable to bring on grave complications. For painful affections of the heart and angina pectoris antipyrin is indicated as a substitute for morphine in injections, because it is equally effective, at least, and causes no cerebral disturbance. When given for asthmatic oppression and suffocating fits, antipyrin cures the patient without suppressing the bronchial secretion. In all the foregoing instances the superiority of antipyrin is therefore well established, but in all cases it has a considerable advantage over morphine. As it does not afford the patient the peculiar inebriating sensations sought by opium-eaters, it is not liable to make of him a morphinomaniac, and relieves his pain quite as effectually as morphine does. To conclude the chapter on the new chemical favorite, Dr. Choupe, in a communication made to the Paris Society of Biology (July 16), recommended *antipyrin in uterine colics*. He administers 1 gramme of it in a rectal enema, with the best results. In one case of severe uterine griping after accouchement, the dose had to be repeated in the course of a few hours, but the pain was permanently relieved. In another instance, a patient suffering from most intense colics on each periodical return of menstruation obtained complete and permanent relief a quarter of an hour after being given an enema of antipyrin. Formerly she

had to be treated with large doses of laudanum, or enough chloral hydrate to produce sleep. From Dr. Choupe's experience it would appear as if antipyrin could also be substituted for chloral hydrate, a medicine that is liable to be perverted into an intoxicant quite as readily as morphine is. In fine, there seems to be much praise now bestowed upon antipyrin. But we may soon expect to be shown the other side of the medal, with, probably, a tendency to run into the opposite extreme.

PARIS, July 22, 1887.

BERLIN.

(From our Special Correspondent.)

The medical life of our national capital is for a time at rest. Professors and students have departed for their summer vacations. The rooms of the medical societies became too warm for even their most eager attendants, therefore the last meeting has been held, and now it is quiet until September, and, after all have recuperated themselves at baths or in the country, the great meetings of the Naturalists and Physicians, the Vienna International Congress for Hygiene and Demography, will make the centre for all who possess a mind for scientific research and enable them to unite in their work. A number of German medical celebrities intend to undertake the trip across the ocean in order to attend the International Medical Congress in Washington. The interest, however, will not be very general; not on account of the expensive and long journey, for the majority of our leaders in medical sciences have a very widespread and profitable consulting practice, but in the leading German circles there is greater interest and sympathy felt with the originally appointed and arranged committee in Copenhagen than in that which was substituted later; and, besides, the Berlin Medical Society, which gives the tone to these things, decided at its last meeting not to send an official delegation to Washington. In this decision one may perceive the sensitiveness which the delegates to the Congress in Copenhagen felt in consequence of certain precedents which the *Chauvanism* of the French members caused. We can only regret that such questions should be brought within the circles of science, and with this feeling wish that the attendance of German scientists at the Congress at Washington may be a large one, without regard to personal questions or national sensitiveness.

If I am to inform you of the circumstance which is causing the greatest interest in medical as well as non-professional circles, I must tell of the illness of the crown prince of the German empire. It is well known through the daily press of America that since January of this year the crown prince has been suffering from a hoarseness. Early in March, Professor Gerhardt discovered a swelling on the left vocal cord, which was treated with galvano-caustic. As neither this treatment nor a cure at Ems brought any visible improvement, the anxiety arose among the physicians who were called in that there might be a malignant growth, and the question of an external laryngeal operation arose. Professor von Bergmann, who was chosen as operator, would not, however, assume the responsibility of so difficult an operation until every means had been used to remove the swelling by internal laryngeal treatment. Therefore the English specialist, Morell Mackenzie, was called in consultation, and, fortunately, he was successful in three visits in removing three pieces of the swelling, which was sufficient to establish the nature of the disease after an examination. Virchow, to whom was intrusted the examination, as being the most competent in such matters, stated in his opinion, published in the German medical journals, that the swelling is a papillary growth united with epithelial proliferation,—pachyderma verrucosa,—and gave a favorable prognostication.

The crown prince is at present under Dr. Mackenzie's treatment, and English journals announce that his recovery is progressing favorably. It is a curious coincidence that just at the time that the crown prince is under the treatment of an English physician, in the Berlin medical faculty the most competent professors of rhinology and laryngology are establishing a clinic and polyclinic under the direction of Professor Bernhardt Fraenkel. This extension of the clinical institutes of the Berlin faculty is the creation of the Prussian kultusminister, Dr. von Gossler, to whose warm interest for the medical standard and medical instruction in the Prussian universities we are indebted for a large number of beneficial innovations.

One of the latest arrangements which is of importance to the medical clinics is the issuing of a clinical annual register, which was ordered by the ministry on the twenty-first of May of this year. This annual register will contain a condensed account of all medical clinics and polyclinics held by the ter-

Prussian universities, giving information as to their accommodations, their usefulness as institutions of healing, as institutes of instruction for the training of physicians, and as institutes for the increase of the knowledge of medical science, and besides, exhaustive statistical specifications of nosology, etc. When one considers that the Berlin University possesses no less than nineteen clinical institutions, one will be able to form some idea of the importance of this literary undertaking authorized by the government. If scientific medicine required it, the physician's position has lately received in Prussia a noticeable encouragement, and it receives a certain official recognition and co-operative assistance in all questions relating to the general health. In each province, through the choice of the physicians, a so-called committee of physicians is elected, the duty of which is to attend to all affairs connected with the medical profession, and to which all complaints and opinions must be brought. Through this the physicians obtain great influence in many matters in which they alone are competent, and, on the other hand, the government obtains a stronger position through the co-operation of the medical profession in all matters pertaining to hygiene. From this we are led to suppose great results will follow.

After all these communications of a general nature we must give a few therapeutic notices. W. Lublinski introduced a patient at the meeting of the Berlin Medical Society whose extreme stenosis of the trachea was greatly benefited by the catheterizing of the windpipe. The patient in his second year was tracheotomized on account of diphtheria. Since then he suffered with asthma, which gradually increased so that at his nineteenth year his inspiration was excessively labored, and audible at a considerable distance.

The examination of the trachea with the mirror showed in the neighborhood of the eighth tracheal ring a contraction across the trachea measuring four millimetres; particularly on the right was a strongly developed tendency to stenosis to be noticed, which contributed to the contraction of the trachea at this point. This point corresponded with the external tracheotomical cicatrix. It was therefore one of the rarest cases where the stricture of the trachea was not caused by syphilis, as was shown by the material changes in the spot referred to. The treatment was as follows: gradual dilatation of the contracted spot by an elastic catheter; beginning with a catheter of the size of four millimetres,

after eighteen applications the size had increased to 1.2 centimetre; as the ordinary catheters were not of sufficient size, Lublinski used conical rectal bougies; already after the fourth catheterizing the contraction was remarkably less, and after the eighteen applications the patient was entirely cured of his infirmity. In the same manner Lublinski has treated four other cases.

- In one case of syphilitic stenosis of the trachea, where below the vocal cords a diaphragmatic membrane appeared, he succeeded, after dividing the membrane by the insertion of the bougie, only in partially increasing the opening, because the patient withdrew from the treatment after his oppression had been relieved. In two cases of rapidly-growing goitre, he succeeded in relieving the occasional asthmatic oppression entirely; also in one case of parenchymatous goitre, with severe compression of the trachea by the isthmus, his treatment was successful.

Professor Ewald has attempted to use salol for diagnostic purposes. It would be possible to decide the time at which food goes from the stomach into the intestine if one could introduce substances into the stomach which would not dissolve there, but would quickly be dissolved in the intestine, and which would be rapidly evacuated and passed through the urine. Salol will not be dissolved in the stomach, as it is insoluble in water, and belongs to the warm, oily substances.

According to Nencki and Sahli, salol divides itself, through the influence of the pancreas, into salicylic acid and phenol, and it was, therefore, quite natural to attach these bodies to the decision of the question as to how quickly matters pass from the stomach into the intestines if one could observe changes in the functions of the pancreas. In a number of demonstrations it was firmly established that salol does not divide itself in the stomach, but the action of the pancreas could not be brought in question; then salol divides itself in the gastric warmth into quite weak alkaline solution; it even appeared that artificial preparations of the pancreas had a retarding influence upon the dissolution of the salol. In the same way the mucous membrane of the alimentary canal, as far as it does not acidify, is in condition to decompose the salol so that it seems to be destroyed by the tissues; it shows that in all healthy individuals salol decomposes in from a half to one hour, and could be recognized in the urine as salicylic acid. Out of thirty-nine experiments, in only one the salicylic acid appeared

after one hour, in six after a half-hour, and in all the others after three-quarters. In opposition to this in individuals in a normal condition, in eight cases of typical dilatation of the stomach the salicylic acid reaction appeared; in seven cases only after two or three hours in the urine; in the eighth case, where the diagnosis could not be decided in all directions, the condition seemed normal, and for this reason Ewald decided that the diagnosis in this case was questionable. The prolongation of the dissolution of salol by the dilatation of the stomach seems to be so typical that the late appearance of the same is calculated to influence the diagnosis of the disease, and, in fact, has influenced it in two cases.

At the last meeting of the Southwest German Association of Neurologists and Physicians for the Insane, which took place at Frankfort-on-the-Main, Professor von Mering announced that he had found a most valuable anæsthetic in amyl-hydrate (tertiary amyl-alcohol); that he has tried the same in sixty cases of insanity, paralytics, and melancholia, insomnia caused by nervousness, and in feverish diseases; a dose from 30 to 75 minims, sleep lasting from six to eight hours; no bad results; the taste is pleasant as that of paraldehyde. Von Mering gives this formula:

R Amyl-hydrate, ʒi;
Aque dest., ʒx;
Ext. liquirit., ʒi.

Dr. Faust (Dresden) recommends in the *Deutsche Med. Wochenschrift* antifebrin in doses from 0.5 to 1 gramme for headache. He noticed upon himself that migraine which defied all other remedies disappeared entirely in from half an hour to an hour's time after one of the above doses; he has obtained the same results in many other cases.

"SNAKE-BITE WEED."

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—I send you by this mail a plant which grows here. It is known as "snake-bite weed." It is regarded as a specific among the natives for the bite of any and all of our poisonous snakes. It has been used by the laity in many cases, in the form of a decoction made by boiling the leaves with sweet milk, and in every case with the most happy results. A few years ago, in our county of Gibson, Dr. A. E. Turner, of Yorkville, Tenn., was treating a case of snake-bite after the most approved methods. The pa-

tient was failing rapidly ; had been bitten by a "cotton-mouth" (if my memory fails me not). The family asked permission to send for a man not far off, who was known to be able to cure snake-bites. Dr. Turner consented. The man came, hunted up the weed of which I send you the specimen, took a handful of leaves, poured on a pint of boiling milk, and as soon as cool enough to administer began with it. He administered the infusion in copious draughts, using several pints. Result : rapid recovery in less than twenty-four hours of what promised to be a fatal case of snake-bite.

At the last meeting of the Gibson County Medical Society, held June 21, 1887, Dr. Stephenson, of Dyer, this county, reported a case he had treated of snake-bite a short time previously, in which alarming symptoms rapidly presented themselves. He gave morphine to allay the pain, and then trusted exclusively to the infusion prepared from this weed, as above described. From the very commencement of the infusion the patient began to improve, and in twelve hours was well. He used no alcohol in any form in his case. It is claimed that it acts more slowly in those cases in which whiskey has been used than where it has not been given.

It is stated that persons bitten by snakes, after tasting the infusion, crave it as long as the snake poison is active, but that as soon as counteracted they no longer desire it. I do not know the plant, hence send it to you to inquire what it is. I do not attempt any description, as you will have the plant before you. I do not know of its having ever been administered in bites of rattlesnakes, but in all of our other poisonous snakes.

The facts that I have stated can be vouched for by many reliable citizens and physicians. What is it, and in what do its virtues consist?

Yours very truly,

T. J. HAPPEL, M.D.

TRENTON, TENN.

[A very large proportion of men and larger animals bitten by poisonous North American serpents recover as a matter of course. If they have chewed any weed as a curative measure (which they usually do), no matter what worthless plant it may be, they attribute their recovery to said plant. Thus it happens that every section, almost every village, civilized and savage, throughout the world, has some plant that is spoken of exactly as our correspondent speaks of this. A mere list of the names of such plants would fill a good-

sized book. Such as have been examined have been found to be more or less inert, this being one of those that has been so investigated.

We have referred the specimen to Dr. H. H. Rusby, who informs us that it is *Hieracium*, probably *Hieracium Gronovii*, L., and from time immemorial has been known as "rattlesnake plantain," because it was supposed to be able to cure the bites of rattlesnakes.—Eds.]

A NEW REMEDY FOR NIGHT-SWEATS.

To the Editors of the THERAPEUTIC GAZETTE:

SIRS:—A regular physician myself, yet I have endeavored through my professional career to take anything which is useful in the practice of medicine from any other branch of medicine, believing, as I do, that so-called allopathy is or should be true eclecticism. We should cull from all ; the mineral and vegetable kingdoms belong to us, and we should not reject a medicine simply because its effects were first discovered by an eclectic, a homœopath, or even by a person not belonging to any school. We should remember that the abuse of aconite by our profession a hundred years ago caused the profession almost to quit the use of it until the sect of Hahnemann commenced to use it in small doses with good results. This taught us that we had abused it, and as a consequence we commenced its use again, in smaller doses than before, adopting a middle ground between former practice and homœopathy, and now what member of our profession would be without it as a remedy in many diseases?

Did we not gain some information here from another sect? Should we be ashamed to acknowledge the benefit? Surely not. I have been often of late years amused, when some new native remedy has been given to the profession, to turn back to King and find that he had used and recommended the same remedy years before. A few years ago *Phytolacca decandra* was brought out as a remedy for mastitis. King had used it and recommended its use years before. We all know the history (as given in the U. S. Dispensatory) of the discovery of gelsemium as a remedy in fever by an old planter in Mississippi ; yet our profession ignored its use until we were forced to use it by the success of the eclectic with it. Just so with one of the most valuable of our remedies in the treatment of the diseases of females, *Viburnum prunifolium*, although Dr. Phares, of Mississippi, called the

attention of the profession to it in an article published in *The American Journal of the Medical Sciences* in 1852. Until a few years ago our profession would not use it, and yet the eclectics have used it for years, and King, in the edition of his work published in 1870, recommends its use. I might go on until I would tire the patience of your readers giving similar instances, but these are sufficient to effect my purpose, which is to cause the profession to stop and think for themselves, and to resolve to take that which is good from any source, having the moral courage to "render unto Cæsar that which is Cæsar's."

I desire to call the attention of the profession to a vegetable remedy, native to our soil, for that troublesome accompaniment of wasting diseases, night-sweats. Do not throw this article aside with the exclamation that "atropine is good enough for me." Atropine is a good remedy, and in the majority of cases answers the purpose; but atropine is a very strong medicine, and must be used with great care. A simpler medicine, answering the same purpose, would certainly be better. I have it, and shall give it to you, and at the same time I shall tell you that it is not a discovery of mine. King recommends it, but I did not get it from him; *I got it from an old negro*,—from the same source that the profession got gossypium. If you can take that from them, why not take this, coming to me from the same source? The remedy is one indigenous to the whole country; it is therefore within the reach of us all; it is the cinquefoil, *Potentilla canadensis*, called by some botanists *Potentilla sarmentosa*. I have stopped night-sweats with it when *atropine failed to relieve*. It is pleasant to take; when drawn it has an agreeable odor, much like table-tea. The manner of preparation is to pour boiling water on a handful of the vine, leaves, and root. Let the patient drink *ad libitum*.

I hope that the members of the profession will give it a fair trial, and report the result through the columns of your valuable journal.

A supply can be obtained through the Southern purchasing agency of Messrs. Parke, Davis & Co., Charlotte, N. C., or through Messrs. Wallace Bros., Statesville, N. C., or, if not too busy, about your own homes. I hope that some manufacturing chemist will (should I be found to be correct in my estimate of it) give to the profession a fluid extract of the root and plant.

Yours truly,

SAMPSON POPE, M.D.

NEWBERRY, S. C., June 14, 1887.

TREATMENT OF EPISTAXIS.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—I have read for a good many years articles on epistaxis in many journals, and from apparently able writers, and have been a good deal surprised at the different ways recommended by the aforesaid writers regarding its suppression.

Now, it is a well-known fact to anatomists and others that the hemorrhage in the vast majority of cases proceeds from the septum nares, and is supplied by a branch of the superior coronary, a branch of the facial, which ramifies upon the septum nares. It enters the opening of the nose just below the alæ nasi, crossing the superior maxillary bone at that point.

Now, in a practice of nearly thirty years, I have had many cases of epistaxis, and have never in a single case failed to arrest the bleeding by compression of the aforesaid artery, with the finger applied over its track, making firm pressure against the bone. This will arrest the bleeding nine hundred and ninety-nine cases in a thousand. I have been called to see cases where other physicians had plugged the nostrils, and injected solutions of ferri persulphas, ice-water, etc., without benefit, and have at once arrested all hemorrhage instantly by the above simple means. Tell them to try it.

Yours truly,

J. ROBINSON, M.D.

MANHATTAN, KAN.

Notes and Queries.

THE REPORT OF THE ENGLISH COMMITTEE OF INQUIRY INTO PASTEUR'S TREATMENT OF HYDROPHOBIA.

The value or uselessness of Pasteur's inoculations for the prevention and cure of hydrophobia have called forth so much controversy that we deem no apology necessary for laying before our readers an abstract of the report on this subject signed by Sir James Paget, T. Lauder Brunton, Dr. Fleming, Sir Joseph Lister, Dr. Quain, Henry E. Roscoe, Dr. Burdon Sanderson, and Victor Horsley, with the editorial comments published in the *Lancet* on this report on July 7, 1887.

The report commences by stating that it was found necessary that some of the members of the committee should, together with Mr. Victor Horsley, the secretary, visit Paris so as to obtain information from M. Pasteur

himself, to observe his method of treatment, and investigate a considerable number of cases of persons inoculated by him; and, further, that a careful series of experiments should be made by Mr. Horsley on the effects of such inoculation on the lower animals. Mr. Horsley's experiments are stated to entirely confirm M. Pasteur's discovery of a method by which animals may be protected from the infection of rabies. If a dog, rabbit, or other animal be bitten by a rabid dog and die of rabies, a substance can be obtained from its spinal cord which, being inoculated into a healthy dog or other animal, will produce rabies similar to that which would have followed directly from the bite of a rabid animal, or differing only in that the period of incubation between the inoculation and the appearance of the characteristic symptoms of rabies may be altered. The rabies thus transmitted by inoculation may, by similar inoculations, be transmitted through a succession of rabbits with marked increase of intensity. But the virus in the spinal cord of rabbits that have died of inoculated rabies may be gradually attenuated by drying the cords, so that after a certain number of days' drying it may be injected into healthy rabbits or other animals without any danger of producing rabies; and by using on each successive day the virus dried during a period shorter than that used on the previous day an animal may be made almost certainly secure against rabies, whether from a bite or from any method of subcutaneous inoculation; and this protection is proved by the fact that if animals so protected and others not thus protected be bitten by the same rabid animal, none of the first set will die of rabies, and, with rare exceptions, all of the second set will succumb.

It may hence be deemed certain that M. Pasteur has discovered a method of protection from rabies comparable with that which vaccination affords against infection from smallpox. It would be difficult to overestimate the importance of the discovery, whether for its practical utility or for its application in general pathology. It shows a new method of inoculation, or, as M. Pasteur sometimes calls it, of vaccination, the like of which it may become possible to employ for protection of both men and domestic animals against others of the most intense kinds of virus. The duration of the immunity conferred by inoculation is not yet determined; but during the two years that have passed since it was first proved there have been no

indications of its being limited. The preventive treatment adopted by M. Pasteur is based on the foregoing experience; but the determination of the success of the method is far from easy, owing to (1) the difficulty of determining whether the bites were really those of rabid animals; (2) the probability of hydrophobia in persons bitten by dogs that were certainly rabid depending very much on the number and character of the bites, whether they were on exposed parts or parts protected by clothing; and in all cases in the amount of bleeding; (3) in all cases the probability of infection may be affected by speedy cauterizing or excision of the wounded parts, or by various washings, or other methods of treatment; (4) the unequal danger of bites of different species of animals, and even of different dogs. In some groups of cases the percentage of deaths among persons bitten by dogs believed to have been rabid has been estimated at only five per cent., in others at sixty per cent.; and the mortality from the bites of rabid wolves has been variously estimated at from thirty-five to ninety per cent.

By the courtesy of M. Pasteur the committee were enabled to personally investigate ninety cases treated by him, these being mostly those which had been earliest treated, in which the periods since inoculation were longest, and living within reach in Paris, Lyons, and St. Etienne. Among the ninety cases there were twenty-four in which the patients were bitten on naked parts by undoubtedly rabid dogs, and the wounds were not cauterized or treated in any way likely to have prevented the action of the virus; there were thirty-one in which there was no clear evidence that the dog was rabid; others in which the bite had been inflicted through clothes. It is estimated, from experience of the results of bites in other cases, that had they not been inoculated, not less than eight among these ninety persons would have died. Not one of them has shown since the inoculation any signs of hydrophobia.

Since, in order to quiet fears, M. Pasteur has been obliged to inoculate many in whom there was no satisfactory evidence that the bite was that of a rabid animal, it might be unjust to estimate the total value of his treatment in the whole of his cases as being more than the rate of mortality observed in them compared with the lowest rate observed in any large number of cases not inoculated. This lowest rate may be taken at five per cent.; and, as between October, 1885, and the end of December, 1886, M. Pasteur in-

oculated two thousand six hundred and eighty-two persons (including one hundred and twenty-seven from this country), the mortality should have been one hundred and thirty. But at the end of 1886 the number of deaths was thirty-one, including seven bitten by wolves, in whom the symptoms of hydrophobia appeared while they were under treatment; in fact, the actual percentage mortality was between 1 and 1.2, showing, on the lowest estimate, the saving of not less than one hundred lives. Of two hundred and thirty-three persons bitten by animals in which rabies was proved, only four died. Without inoculation at least forty would have died. Among one hundred and eighty-six bitten on the head or face by animals in which rabies was proved, only nine died, instead of at least forty. Of forty-eight bitten by rabid wolves, only nine died, instead of nearly thirty. Between the end of last December and the end of March, M. Pasteur inoculated five hundred and nine persons bitten by animals proved to have been rabid; only two have died, one of these, bitten by a wolf a month before inoculation, dying after only three days' treatment. The committee think it, therefore, certain that the inoculations practised by M. Pasteur have prevented the occurrence of hydrophobia in a large proportion of those who, if they had not been so inoculated, would have died of that disease. And his discovery shows that it may become possible to arrest by inoculation, even after infection, other diseases besides hydrophobia. His researches have also added very largely to the knowledge of the pathology of hydrophobia, and supplied a sure means of determining whether an animal which has died under suspicion of rabies was really affected with that disease or not.

The question whether the method itself entails risk to health or life is then discussed, the distinction between the ordinary method and the "intensive" method being pointed out. By the first method there is no evidence or probability of any danger to health at all; but after the intensive method, which is only practised in the most urgent cases, deaths have occurred which might possibly be attributed to the inoculations rather than to the original infection. Yet in the worst cases the intensive method is relatively more efficacious than the ordinary method, nor is the rate of mortality greater after the former method than after the latter. Certain cases, one of which is detailed, have, however, excited suspicion from the mode of death. The case related is that

of a man bitten by a rabid cat at the Brown Institution, treated by M. Pasteur the next day by the intensive method, continued during twenty-four days, and dying about a month later with symptoms of acute ascending paralysis. The man was very intemperate, and had been exposed to chill while crossing the Channel on his return home. Mr. Horsley proved that his death was due to the virus of rabies, by using a portion of his spinal cord for the inoculation of rabbits and dogs, who died with characteristic signs of paralytic rabies, such as usually occurs in rabbits. Yet it is by no means certain that the fatal issue in this and in other cases treated by the intensive method was not due to the original infection. M. Pasteur has, however, greatly modified this plan of treatment, which he employs in none but the most urgent cases.

The final paragraphs of the report, which embody practical suggestions, may be given *in extenso*:

The consideration of the whole subject has naturally raised the question whether rabies and hydrophobia can be prevented in this country. If the protection by inoculation should prove permanent, the disease might be suppressed by thus inoculating all dogs; but it is not probable that such inoculation would be voluntarily adopted by all owners of dogs, or could be enforced on them. Police regulations would suffice if they could be rigidly enforced. But to make them effective it would be necessary (1) that they should order the destruction, under certain conditions, of all dogs having no owners and wandering in either town or country; (2) that the keeping of useless dogs should be discouraged by taxation or other means; (3) that the bringing of dogs from countries in which rabies is prevalent should be forbidden or subject to quarantine; (4) that in districts or countries in which rabies is prevalent the use of muzzles should be compulsory, and dogs out of doors, if not muzzled or led, should be taken by the police as "suspected." An exception might be made for sheep dogs and others while actually engaged in the purposes for which they are kept. There are examples sufficient to prove that by these or similar regulations rabies, and consequently hydrophobia, would be in this country "stamped out," or reduced to an amount very far less than has hitherto been known. If it be not thus reduced, it may be deemed certain that a large number of persons will, every year, require treatment by the method of M. Pasteur. The average annual number of deaths from hydrophobia

during the ten years ending 1885 was, in all England, 43; in London alone, 8.5. If, as in the estimates used for judging the utility of that method of treatment, these numbers are taken as representing only five per cent. of the persons bitten, the preventive treatment will be required for eight hundred and sixty persons in all England; for one hundred and seventy in London alone. For it will not be possible to say which among the whole number bitten are not in danger of hydrophobia, and the methods of prevention by cautery, excision, or other treatment cannot be depended upon.

The editorial comments of the *Lancet* on this report are as follows:

The report of the Hydrophobia Committee has appeared at last, and, it must be confessed, its character supplies a sufficient reason for the delay that has occurred in its production. To consider the evidence that has been accumulated at the Pasteur Institute, and to form an opinion as to the alleged results, could not, indeed, have needed so long a time as a whole year; but to verify those results by independent investigation, to test the practical value of the inoculations as a means of preventing hydrophobia, must, it is evident, require a considerable time; and the Committee is to be congratulated on having attained a definite conclusion in the time they have taken.

The definite character of the conclusion reached will probably render the report a surprise to most members of the profession who have compared the divergent opinions that have been so freely expressed by men not ill qualified to judge, and have duly realized the difficulty of the investigation and the many sources of fallacy arising from the character of the facts themselves. It is certainly satisfactory that men so well able to weigh the evidence and to observe the facts, after having had the fullest opportunity of investigating the results obtained at the Pasteur Institute, should have come with one accord to an opinion so precise. Without doubt their verdict is the most important yet pronounced upon the subject, and must go far to decide the question of the prophylactic value of the inoculations of Pasteur.

The process itself was studied in Paris by three members of the Committee,—Sir Henry Roscoe, Dr. Burdon Sanderson, and Dr. Lauder Brunton. A series of experiments were instituted after the return of these members by Professor Victor Horsley, while the

other members of the Committee, Sir James Paget, Sir Joseph Lister, Dr. Quain, and Dr. Fleming, formed an opinion on the facts submitted to them. Those facts are fully stated in an appendix to the report, so that it will be possible for all persons who are interested in the subject to weigh the evidence and the conclusions. It can hardly be doubted that those who are competent to form an opinion will agree in the main with that expressed by the members of the Committee.

It must not be assumed that all parts of the report are of equal value. We have alluded to the sources of fallacy that lurk in the statistics of Pasteur; the members of the Committee have taken due account of them, and have endeavored as far as possible to avoid them. To eliminate them altogether is impossible, and the conclusions reached cannot have more than a very high degree of probability. But it is otherwise with the experiments instituted by the Committee: these are apparently free from all sources of error. They are not numerous, it is true, but their results are unequivocal, and seem to leave no room for doubt that the inoculation with the weakened virus of rabies confers an immunity from the disease. The inoculation with emulsion of the spinal cord of rabid rabbits preserved a series of dogs from rabies, although the most certain conceivable method of inoculation was employed,—a bite from an animal in the acute stage of the disorder. In no case did the animal contract rabies, whereas of other unprotected animals bitten at the same time the majority contracted the disease. The experiments thus seem to leave no doubt of the efficiency of inoculation in rendering harmless a subsequent infection. They prove that the malady, as produced by the attenuated virus, is trifling, and they thus confirm two of the most important statements of Pasteur. On the question whether inoculations, made after a bite has been inflicted by a rabid animal, confer the same immunity,—a question of paramount importance,—the original researches throw no direct light. But the confirmation of the conclusions of Pasteur, in so far as they have been reinvestigated, is not without its significance, for it naturally increases the readiness to accept also those conclusions that have not been the subject of independent study. The statistics of Pasteur have been subjected to a careful examination by the Committee, and the conclusion from the analysis is entirely in favor of Pasteur's method. A considerable number of cases were personally investigated, so far as inves-

tigation was possible after the lapse of a considerable time. The facts of these cases, the means employed to prevent infection,—washing, cauterization, etc.,—and the evidence as to the condition of the dog which bit the patients, are described in the appendix to the report. The conclusion drawn from these facts is that in many of the cases the dog was unquestionably rabid, and that a certain proportion of the sufferers would have died from hydrophobia if they had not been treated, and who, being treated, have not suffered from the disease. The conclusion that the method has saved a considerable number of lives, and that it is at present, and probably will be for long, the only mode of saving from death those who have been bitten by a rabid dog, affords strong support to Pasteur's conclusions, and, we need hardly say, must have most important practical results.

Nor is this all. By the opponents of Pasteur it has been alleged that the dangers of his inoculation are scarcely less than those of the bites of rabid animals. It has been stated that many deaths have occurred in consequence of the treatment, and that some of the patients have actually been affected with paralytic rabies in consequence of the inoculations. On this point also the verdict is in favor of Pasteur. It is, perhaps, doubtful whether this verdict rests on so firm a foundation as does that of the protective power of the treatment. The report confines itself to one of the cases of death after the treatment,—the case of the man Goffi, who was bitten at the Brown Institute, and died in St. Thomas's Hospital. On this case the report throws a new and startling light. It will be remembered that the cause of death was spinal paralysis, and its connection with rabies was denied. Mr. Horsley proves that the disease was paralytic rabies; the results of inoculations make the fact unquestionable. The treatment was certainly unsuccessful, and it is suggested that almost continuous intoxication may have prevented its success. Was the malady due to the original infection or to the "preventive treatment"? The Committee suggest the former as the probable cause, that paralytic rabies may be more common than is supposed, and that the disease known as acute ascending paralysis, or Landry's paralysis, may be, often at least, paralytic rabies. If this conclusion be correct, it is strange that paralytic rabies should not be observed more frequently as the distinct sequel to the known bite of a rabid animal. It seems more probable that, if the death of

Goffi was the result of the bites he received, the form of the malady was determined by the influence of the inoculations. But the conclusion of the Committee seems to be that, although the strong virus formerly employed may have entailed some evil consequences, the method now employed is free from serious danger.

We have said that the report of the Committee can hardly fail to have important practical results. The government has ordered the inquiry in response to a public demand, and, the verdict being so clear and strong, the establishment of a Pasteur institution in this country seems now to be their clear duty. Whatever other effect the report may have, it will certainly compel increasing numbers of persons who have been bitten by dogs, rabid or not rabid, to seek what is said to be a certain safeguard against a terrible possibility. That they should have to go to a foreign country for the treatment which the Government Committee consider some at least of the bitten persons will require, will be intolerable. The inevitable result of the report must surely be the establishment of a Pasteur Institute in this country, and, after such an answer as the government has received to its inquiries, the task can scarcely be left to private benevolence.

A CASE OF POISONING FROM CONIINE.

SCHULZ reports in the *Deutsche-Medicinische Wochenschrift* for June 9, 1887, the following case.

It is the custom of Professor Schulz during his lectures on materia medica to circulate among his hearers samples of the drugs lectured upon for inspection. The alkaloid coniine was so arranged that the characteristic odor was plainly perceptible to those who examined it. Although this custom had been observed for some time, no accident had occurred. On one occasion, however, after coniine had been exhibited, the lecturer was informed that a student had been poisoned by inhaling the exhalation of the drug. He proceeded at once to his lodging, and found the case as follows:

The patient, 22 years old, and strong and healthy, had, on the day previous, smelled of the coniine repeatedly, as he had a nasal catarrh, which made it difficult for him to obtain the odor. He noticed, on going to his lodging after the lecture, that the odor seemed to be still present. He was taken with a progressive enfeeblement of his limbs; he could

not keep his eyes open ; he had a painful sensation of burning about the conjunctivæ, and was finally compelled to lie down. The prostration increased, and power over the extremities was lost, although the sensorium was uninfluenced. Severe headache and strong pulsation in the temporal regions ensued. When found by an acquaintance and put to bed, some two hours after the patient noticed the first symptoms, he was almost speechless, the words being spoken very slowly and with great effort. After he was placed in bed a diffused sensation of heat was experienced, and those who were with him supposed fever to be present. This was followed by free perspiration and also profuse secretion of tears. The patient could not rest during the night. Confusion of ideas, images formed from surrounding objects, and utter failure of connected thought were observed. On the following morning the patient's condition was ameliorated : headache and prostration continued, but were less severe. The slightest motion, however, occasioned a profuse perspiration. The nasal catarrh, which the patient had before he was poisoned, had disappeared.

When seen by Schulz, twenty-four hours after he was poisoned, the patient presented no abnormal appearance. He gave a clear account of all which had happened, but complained of headache. Pulse full and soft, 88 ; temperature 98.7°. When he changed his position in bed the perspiration appeared in profusion upon the head, buttocks, and extremities. Constipation and loss of appetite for food and tobacco were present. The following night a normal rest was obtained, and the patient speedily recovered without treatment.

In the literature of the subject Pöhlmann has described the headache and supra-orbital pain following the giving of conium. Schroff and his pupils observed the diaphoretic action of the drug, and endeavored to define the production and limits of this effect. The general symptoms, the paralysis of the muscles about the eyes, the failure of speech and effect upon the circulation are typical of the action of the poison as described by Plato in his description of Socrates's death.

For a full account of cases of poisoning by this drug the reader is referred to Schulz's article on "Coniin" in Eulenberg's *Encyclopædia*.

UNCOOKED FOOD IN SUMMER DIET.

The discovery of animal alkaloids, their general recognition as a factor in the phenomena of health and disease, may perhaps induce many practitioners to reconsider their opinions with regard to fruit diet. No reasonable amount of fruit, if eaten when ripe and during proper seasons, will induce diarrhoea in healthy subjects. Many erroneously attribute summer dysentery or persistent diarrhoea to excessive indulgence in fruit. This doctrine we have always held to be an exaggeration. To the over-abused stomach, indeed, fruit may possibly prove inconvenient, for the digestive system may be so far impaired as to assimilate only with the greatest difficulty the most natural and wholesome of foods. With children, and robust and healthy people generally, however, this does not apply, and a fruit diet, so far from being noxious, will, on the contrary, prove highly beneficial. Its cooling and antiscorbutic properties are eminently calculated to purify the blood, cleanse the tongue, palate, and stomach, cause gentle and regular laxation, and, as a necessary corollary, induce a clear and fresh complexion. A person who indulges in fruit diet during summer will rarely feel that oppressive heaviness after meals, which is so commonly complained of, or be inconvenienced by heat rash. Meat necessarily contains a certain amount of ptomaines, the proportion of which increases during the hot months somewhat alarmingly, and it therefore really becomes an inappropriate food in summer. This applies even to those who are obliged to lead an active life. A heavy meal of animal food conduces to oppression, excessive heat, slow and irregular digestion, accumulation of ptomaines, and consequently induces over-production of the highly deleterious leucomaines. It would be well for practitioners to consider whether many of their patients should not be subjected to a new dietetic regimen during the hot months. We would recommend a liberal amount of fruit either directly before or at breakfast, banishing from the table the customary bacon and salt or cured fish. From the mid-day meal of people who dine late we would eliminate entirely every particle of flesh, and substitute either a diet solely composed of uncooked fruit and dry bread, brown or whole meal being preferable, or fruit and farinaceous puddings with milk. Great numbers of people, invalids and strong, active workers alike, would find such a change improve their health materially and increase their enjoyment of life to an extent

of which they can hardly conceive without a trial.

Fruit is of great medicinal value, for the free acid contained in it (in the case of the strawberry and gooseberry about one and a half per cent., in that of the raspberry and currant rather more), besides being an effective antiscorbutic, acts as a calcareous solvent. Free fruit diet, if persevered in more generally, would mean less gout, less gravel, less urinary calculi, and other more or less kindred diseases. In most cases an orange or lemon would be a far better "eye-opener" than the matutinal cup of tea or somewhat bilious rum and milk which certain of the public so delight in.

With regard to children, we consider that an unlimited diet of fruit would do no harm, always provided it was indulged in during the day, and not after a heavy meat meal, or late at night. Strawberries, gooseberries, plums, cherries, etc., are not only nourishing, but their use does away with the oppressive feeling so often suffered by children after meals, keeps them cool, and out of mischief. Almost invariably, when we trace inconvenience from fruit-eating in children, we find that the feast has been a clandestine one, and the distressing symptoms are probably due to over-indulgence in unripe or hot fruit. Proper supervision in the distribution of fruit to the juveniles is all that is required. Fruit should be ripe and cool; hot from the rays of the sun, it becomes less indigestible and more likely to do harm, often inducing more or less acute febrile symptoms, together with evidence of gastric disturbance. With the evident danger of alkaloid-poisoning before us, in this age when we rightly consider prevention better than cure, the profession should turn their attention more earnestly to the question of fruit diet, independently of the "grape-" or other "fruit-cure," the vaunted efficacy of which some are not unnaturally unwilling to credit.—*Medical Press*, July 13, 1887.

PROGRAMME OF THE INTERNATIONAL MEDICAL CONGRESS.

The Chairman of the Committee of Arrangements announces the following programme:

First Day—Monday, September 5.—The Congress will assemble at Albaugh's Opera-House at 11 A.M., and will be formally opened by the President of the United States, to be

followed by a short address of welcome by the Secretary of State; address by the President of the Congress; report of Secretary-General and Chairman of Committee of Arrangements. Adjourn at 1.30 P.M. From 3 to 6 P.M., meeting of the sections at their respective halls. Evening *conversazione* at U. S. Pension Hall from 8 to 11 P.M.

Second Day—Tuesday, September 6.—Meeting at 10 A.M. at Albaugh's Opera-House. General addresses by Drs. Flint and Semmola. Sections will meet at 11 A.M., and adjourn at the same hour with Congress at 1 P.M. In the afternoon the sections will meet from 3 to 6 P.M. In the evening it is expected that a reception will be given by the President of the United States, and the Corcoran Art-Gallery will be thrown open to the members and their families.

Third Day—Wednesday, September 7.—The Congress will meet at 10 A.M. General addresses until 1 P.M. The sections will meet as usual at 11 A.M., and adjourn at 1 P.M. Afternoon meeting of the sections from 3 to 6 P.M. Evening reception to the members and their families by the citizens of Washington.

Fourth Day—Thursday, September 8.—General meeting at 10 A.M. Addresses, if not previously delivered. Meeting of the sections at 11 A.M.; adjourn at 1 P.M. Afternoon, sections meet from 3 to 6 P.M. General reception buffet banquet at U. S. Pension Hall from 8 to 11 P.M.

Fifth Day—Friday, September 9.—General meeting at 10 A.M. Transaction of business affairs of Congress. Meeting of sections at 11 A.M., and adjourn at 1 P.M. Afternoon, sections meet from 3 to 6 P.M.

Sixth Day—Saturday, September 10.—General meeting at 10 A.M. Adjourn at 11 for visit to Mount Vernon.

On Sunday or Monday, the day not yet determined upon, an excursion train will leave Washington with the foreign members and their families for Niagara Falls, under the escort of a part of the Committee of Arrangements, selecting the route which will afford our foreign brethren an opportunity to see some of the most interesting and thrifty portions of our country, as well as very beautiful scenery.

In completing the details of this programme it may be necessary to make some slight modifications.

SUMMER DRINKS.

A continuance of fine weather and of warm sunshine, in spite of the rain upon St. Swithin's day, and occasionally since, implies a continuance of thirst as a necessary consequence of the free perspiration which is likely to attend all muscular movement. In England tropical heat is so rare that we cannot afford to dislocate all business engagements during the middle of the day, and we suffer accordingly; our ceaseless activity is followed by copious perspiration; this in turn by rapid evaporation and its ordinary risks; then, owing to the enormous drain of water from the system by the skin, the various secretions, more particularly those of the mucous and salivary glands, are diminished, and dryness of the mouth and thirst result. There is naturally great temptation to slake thirst whenever practicable, and to re-establish the balance of fluid in circulation. How this can best be effected becomes, therefore, a question of great importance at the present season. Many persons doubtless increase their discomfort by injudiciously drinking quantities of cold water, which serve to stimulate the sweat-glands, and so to increase the amount of loss by perspiration. While the "cold-water-cure" is to be deprecated, it should not be forgotten that it is equally, if not more foolish, to indulge freely in alcoholic stimulants. For the time they certainly allay thirst by stimulating the salivary glands, but after absorption they promote relaxation of the arterioles and increase the rapidity of the heart's action, and are hence followed by a speedy "Nemesis." The cooling influence of acids should be remembered in times of high temperature. The acid employed will necessarily be largely a matter of taste. Most persons would shrink from the use of dilute solutions of citric or tartaric acid, and yet many find relief from a beverage composed of diluted and unsweetened lemon juice. Should cider be found to agree with the digestion, a very pleasant summer drink may be compounded of equal parts of cider and of any pure form of effervescing water, the Hereford or rough cider being, as a rule, more palatable than the sweetened forms. Cold tea has many adherents, but it is worth noting that it should be poured out while still hot, and not allowed to stand to cool in contact with the leaves, since under these conditions the astringent properties become more completely dissolved, and the tea becomes less palatable and more likely to disorder digestion. Tea has, however, its disadvantages, the chief undoubtedly being the amount of wakefulness produced by it when

taken late at night. With regard to iced drinks, it should be borne in mind that the refreshing sense of coolness resulting from their employment in bulk is speedily followed by reaction. This is less felt when a cardiac tonic is employed in this form,—as, for example, the iced coffee so commonly provided at afternoon parties. "American drinks," also, are to be employed only in great moderation and with caution, being liable to induce catarrh of the stomach during the period of reaction following the primary chill. Of the so-called "temperance drinks" and of the more common lemonade and ginger-beer there is little to be said, provided that the purity of their source can be insured; it is, indeed, on this account that we would urge the employment of the more troublesome but infinitely safer home-made lemonade, prepared with boiling water, and rendered more agreeable by the subsequent addition of any pure effervescing water. Sugar should not be added in any quantity, as it evolves so much heat during oxidation. It is curious to note that the French, who, in hot weather, so carefully and wisely avoid alcohol, overlook this influence of sugar, and indulge freely in summer drinks of syrups and *eau sucrée*.—*The Lancet*, July 23, 1887.

THE DETECTION OF MORPHINE-TAKING.

DR. OSCAR JENNINGS recommends, in cases of suspected morphinomania, the examination of the urine for morphine or opium salts. He recommends the two following reagents:

First.—The double iodide of mercury and potassium (HgCl 13.546, KI 49.80, to a quart of water). This reagent gives a yellowish white precipitate with opium alkaloids.

Second.—The iodized iodide of potassium (I 10 parts, KI 20 parts, to 500 parts of water). With morphine salts this reagent gives a brown or yellowish precipitate.

If the quantity be too small to discover by one of these reagents, boil the urine to a third, treat with tartaric acid; then dissolve the tartrate of morphine thus formed with amyl alcohol; decompose the salt with ammonia, and if morphine be present, the solution should show a blue color on adding the perchloride of iron. A slightly less troublesome proceeding will detect meconic acid and prove the taking of opium; evaporate, wash with alcohol and boiling water, neutralize with magnesium carbonate, and treat, after filtration, with solution of iron perchloride. A blood-red color is characteristic of meconic acid.

MERCURIAL INJECTIONS.

A discussion has recently been taking place in the Brussels Medical and Scientific Society as to the relative advantages of mercurial injections and inunctions combined with internal medication. DR. THIRY prefers the latter method, as he thinks injections are attended with serious risks and inconveniences. M. ED. DE SMETH, on the other hand, practises injections largely—in fact, always—when mercury is indicated in syphilitic patients. At present there are in his wards twenty-four such cases in which no less than nine hundred injections have been given without any accident occurring; and M. de Smeth thinks that as, apart from his own practice, M. Martineau has reported a series of one hundred and eighty thousand injections without any accident, Lewin three hundred thousand with twenty abscesses, and Paikert five thousand without any, it cannot be said that this form of treatment is more liable to inconveniences than other forms. He points out that there is a great difference between injecting insoluble salts, as calomel and the yellow oxide, in the way recommended by Scarienzo, upon which method M. Thiry's experience of injections was mainly gained, and injecting soluble salts, which is the plan he himself prefers and follows. Here, he says, the only objection to the injections is that the patient must be regularly seen by the doctor, which in private practice is sometimes inconvenient. Of course care must be taken that the syringe is perfectly clean and that the liquid is well filtered. In order to illustrate the occasional importance of the rapid action which can only be obtained by the method of injecting soluble salts of mercury, M. de Smeth mentions a case of syphilitic laryngitis of so urgent a character that it was thought that laryngotomy would be needed. However, by means of hypodermic injections repeated five or six times during the course of twenty-four hours all danger was averted.—*The Lancet*, June 25, 1887.

DISCOVERY OF DIAMIDE.

A very interesting discovery has just come to us from Germany. The author, THEODOR CURTIUS, investigating diazoacetate of ethyl, found that by the action of potash a yellow crystalline compound was obtained, which, in its turn, was changed by sulphuric acid into white crystals, which proved to be the sulphate of the long-sought base diamide N_2H_4 . The important compounds called amides and

amines contain, as is well known, the radical NH_2 , formerly known as amidogen, which is the true analogue of hydroxyl, OH, and cyanogen, CN. This radical has at last been isolated, but, as in the case of the other normal radicals, the formula must be doubled, and the free compound is N_2H_4 or $NH_2.NH_2$. The base is easily obtained from its sulphate by the action of alkalies, and is a very interesting substance, about which we shall soon know more. It is a gas soluble in water, and fuming with hydrochloric acid. Its solution is a base, and turns red litmus to blue, and yet it is in smell and in other respects different from ammonia. It is a powerful reducing agent, readily reducing Fehling's solution and nitrate of silver. Its salts are suddenly decomposed by heat, and yield nitrogen when treated with nitrous acid, which last reaction shows their true amidic nature. The further study of this most interesting substance will be awaited eagerly by all chemists.—*The Lancet*, July 2, 1887.

A CONVENIENT FORMULA FOR NAPHTHALIN.

BOUCHARD suggests the following :

R Naphthalin, gr. lxxv;
Sacchar., gr. lxxv;
Essent. bergamot, gtt. ii.
Div. in chart. 20 in num.
Sig.—One powder every hour.

The drug may also be placed in gluten-capsules, each of which contains four grains.

The drug is an excellent antiseptic. It is generally very well borne, and may be given in quantities as great as from 50 to 75 grains daily. It has no effect upon the circulation, but is simply an intestinal antifermentative and germicide.—*Archives de Pharmacie*, No. 6, 1887.

OXALIC ACID IN ASTHMA.

Although a dangerous poison, oxalic acid seems to have proved very beneficial in the treatment of ten cases of asthma by DR. V. PAULET. He calls attention to the difference of action when the drug is given in a concentrated and when it is given in a diluted form. When administering the drug it is necessary to bear in mind the following considerations : 1. The dose should be in proportion to the weight of the body ; 2. Time of administration ; 3. The state of health or of the disease of the subject ; 4. The idiosyncrasy of the patient.—*National Druggist*, July 1, 1887.

HYGIENIC THERAPEUTICS—A LECTURE ON MASSAGE.*

BY PROFESSOR DUJARDIN-BEAUMETZ, Paris, France.

GENTLEMEN,—I desire to devote two lectures to massotherapy, and I shall follow in these lectures the order which I adopted when treating of kinesitherapy. In the first lecture I shall give a historical survey of massage, and shall study its modes of application and its physiological effects, and

* An abstract of two lectures delivered in Cochlin Hospital, and translated from advance sheets by E. P. Hurd, M.D.

I shall devote the second lecture to its therapeutic uses.

The word *massotherapy* may appear to you somewhat strange, I fear even that it may seem uncouth, but it is sufficiently expressive of the meaning which I attach to it, namely, the application of massage to therapeutics. Moreover, writers have protested against the use of the word *massage* itself, and Dally rejects it altogether. He would have us give to the sum of therapeutical means included under this term the name of *manipulations*. But it seems to me idle to waste disputation over the grammatical validity of a word which is now in good medical usage, and I pass on to the consideration of my subject in its historical aspect.

On this part I shall be brief, for the history of massage is in many points inextricably blended with that of gymnastics, and if it behooved me to treat the latter subject with a fair measure of completeness, I have only to refer you to details in my first lecture, which equally concern massotherapy. There are, however, particulars in this history which deserve to be put in clear light, and to this task I shall now apply myself.

We find among almost all nations in the most remote periods of their history practices of massage in common usage. Review the writings of the principal navigators, consult in particular the narrative of Captain Cook, and you will see that in Tahiti, in New Holland, and other parts of Oceania, the primitive people employ the practices of massage for the treatment of diseases, and the means which they make use of are the same as those which we now employ. Thus, in the island of Tonga, in Oceania, under the name of "*toogi-toogi*," the natives have a medical practice which consists in prolonged and gentle percussion with the fist, and under the name of "*miti*," or "*fota*," they mean the kneading of muscles and frictions. In New Holland the same custom prevails, and it is chiefly the sorcerers, the *Mulgaradocks*, who practise these manœuvres of massage. Interrogate also the travellers of Central Africa, and they will tell you that among the inhabitants of the African continent the sorcerers practise the same pressures and the same rubbings.

Moreover, these rubbings and these pressures are, so to speak, instinctive, and whenever an individual suffers in any part of his body, he endeavors by these manœuvres to get rid of his pains. It is not surprising, then, that we find these methods in vogue from the very dawn of human history, and that we also see traces of them in the current medical practices of all nations, though modified according to climates and according to temperaments.

While in the East, where the cutaneous circulation is very active, and where there is a necessity for ridding the skin of all impurities resulting from the excessive performance of its excretory function, the most popular methods are gentle frictions, scratchings, kneadings, associated with vapor-baths, such as are put in usage in the Moorish or Hamman baths which are found in abundance throughout the entire East, among the people of the North, on the other hand, there is an indication to invigorate the circulation, to habituate the skin to undergo sudden transitions from

one temperature to another, and this is the benefit sought from vapor-baths, cold-water baths, and flagellations, such as characterize the Russian baths.

Moreover, we find in our own times "survivals" of primitive massage practices in the manœuvres resorted to by bone-setters. Before massage, as of late years, took a definite scientific character, these bone-setters were quite in repute as performers of massage, and it may be safely said that there is scarcely a populous locality, or even obscure hamlet, in France at the present day where some of these "natural bone-setters" do not exist to be a thorn in the flesh to the regular practitioner.

But while on this subject of massage from a purely scientific stand-point, it may be stated that in the Chinese book "*Cong-fou*," of which I spoke to you in the first lecture, we find an exact description of all the practices of massage. You will even find there an account of those concentric and excentric movements, which, according to Meding, constitute the basis of Swedish gymnastics. The engravings, moreover, which accompany the "*San-tsai-ton-houi*," show us how the Chinese practise massage.

In India, rubbings and percussions are also in popular usage, and Anquetil and Petit-Radel have insisted on this point. The Hindoos, besides making frictions with the mud of the Ganges, rub thoroughly and knead the muscles, an operation to which they have given the name of *chamboning*, which the English have translated *shampooing*, and which every barber knows how to apply so vigorously to the heads of his customers.

It can easily be shown that the Greeks and Romans were also in the habit of employing massage. Among a thousand equally pertinent examples I may cite this observation of Hippocrates: "At Elis the wife of a gardener was seized with a continuous fever; she took evacuant remedies without any relief. In the belly, below the umbilicus, there was a hard swelling, protruding above the level of the surrounding parts; this swelling caused violent pain. *The attendants were set to rubbing and kneading this tumor with all their might, their hands being well smeared with oil.* Soon blood in abundance was passed by stool. The patient experienced marked relief, and got well." Here, you see, was a case of intestinal obstruction, and massage overcame the obstruction and effected a cure. Oribasus, also, in his compilation, indicates all the practices of massage, giving the minutest details.

The RENAISSANCE, it must be admitted, added little to what the ancients knew respecting massage. I ought, however, to mention a curious tract by Paullini, which appeared about the end of the seventeenth century, and was entitled "*Flagellum Salutis*." The same subject was taken up a hundred years later (in 1795) by Meibomius, under the following head: "*On the utility of flagellation in medicine, in the pleasures of marriage, and in the functions pertaining to the loins and kidneys*." This title leaves no doubt as to the benefits which these two writers ascribed to flagellation in the treatment of certain affections, and in particular of frigidity.

As I have just told you, the practice of massage remained almost exclusively confined to the lower classes, being abandoned to the country quacks, and it is only within a few years that massage has obtained the right of domain in medicine. This movement of scientific renovation took place almost simultaneously in France, in Holland, and in Germany.

In France, in 1837, Martin represented to the Medical Society of Lyons the marvellous results which he had obtained from massage in the treatment of lame back and lumbago. Lebatard and Ellaume in 1860,* Rizet in 1862,† showed the advantages which may be obtained from massage in sprains; but we must come down to the thesis of Estradère in 1863‡ before we find a comprehensive treatise on the effect of massage. Works on this subject have since multiplied, and I cannot even give you a full list of their titles, but I cannot refrain from indicating the great value which I ascribe to the brilliant work of Estradère, who was the first to put in clear light the physiological effects of massage, and the therapeutic benefits to be derived therefrom. Nevertheless, it is not France alone that derived all the benefits of this work. Holland has reaped advantages from it under the influence of Mezger and his pupils, and we see even now patients flocking from all parts of Europe to Mezger's clinic to essay the effects of massage under the direction of that celebrated masseur.

Mezger has written but little. The only treatise of his which we possess (and it is of very modest dimensions) was published in

1868 at Amsterdam.§ He says in this work that it is his intention to devote himself particularly to those special applications of gymnastics which are called *frictions*, or, better still, *massage*. He adds that in 1853 he began at Amsterdam the treatment of sprains by this means; that little by little he improved his system, and that since 1861 he has occupied himself exclusively with massage. Mezger has gathered around him numerous pupils.

In Sweden, it is under the influence of Berghmann, of Helledag, and especially of Amström, that the method of Mezger has spread. In Russia, Berglind has been the pioneer in this direction.¶ Lastly, in France, we owe to Norström, of Stockholm, a complete exposition of Mezger's method.¶

In Germany, it is under the influence of Rosbach, of Busch, and particularly of Schreiber** and of Reibmayr, that massage has taken a truly scientific development. The work of Schreiber has been translated into French, and more recently still into English; Reibmayr's has been translated into French and annotated by one of my pupils, who has made a specialty of massage.††

The methods of massage are divided (like those of gymnastics) into two great groups,—massage without apparatus, and massage with apparatus. As for massage without apparatus, the only kind practised by Mezger and his followers, we have to distinguish four different manœuvres,—passes (*effleurage*), frictions, kneadings, and tappings.

Effleurage‡‡ consists in light passes made with the hand. Sometimes it is the palm which is used, sometimes the fingers, or, more properly speaking, the pulps of the fingers or thumbs, or even the phalangeal joints. In the latter instance the fist is closed, and it is with the extremity of the articulations of the phalanges with the phalanges that the skin of the patient is rubbed. The Germans give to this kind of massage the name of *kammgriff* (combing).

The frictions consist, as their name indicates, in making with the hands centripetal

‡ Estradère, "On Massage: its History, its Manipulations, its Therapeutic Effects" (*Thèse de Paris*, 1863).

frictions, which are rendered rhythmical by alternating the movements of the hands.

Kneading is performed sometimes by pinching up a muscle, or by kneading it with the two hands, or, in another manner, by rolling with both hands the muscles of a region.

Tapping movements consist in tapping, slapping, or stroking certain regions. Slapping is made with the palmar surface of the hand, the skin being smitten more or less forcibly. Stroking is done with the inner border of the hand, with which the part on which one wishes to operate is percussed with greater or less force.

The apparatuses employed in massage are quite numerous, and I can only mention the principal. Sometimes the instrument is a simple affair,—the flesh-brush or glove, the *strigilis* or flesh-scraper (*raclette*), which we find employed in remote antiquity, as is seen in one of the masterpieces of ancient statuary. Then come the more or less complex rollers (*roulettes*), with which of late years electricity has been conjoined, as in Butler's roller, Stein's cylinder. Then there are the wooden mallets, the ferules, the battledoors, whose number and whose form are variable, and whose application goes back to the most remote times. It is even probable that the old proverb, *Se battre les flancs*, etc. (*about beating the loins*), had an allusion originally to the custom of smiting the sides of the abdomen with a wooden paddle or a leather thong.

Among these latter instruments I must mention the percussor of Sarlandières, and the dorsal beater of Klemm, and the more complex muscle-percussor, which he has also recommended. I must also mention in passing the electric percussors, moved by electricity, and devised by Granville, which give an absolutely rhythmical series of percussions, and lastly, the more complicated apparatus which Zander has invented, and which also determines more or less prolonged percussions and strokes of considerable intensity.

These apparatuses, however, are mostly abandoned, at least in France, and even by Mezger in Holland, and it remains for me now to discuss the two following points: first, the utility of fatty inunctions in conjunction with the practice of massage; and, second, whether massage should be performed on the naked body, or through a certain amount of clothing.

Estradère, without attaching any great importance to ointments and inunctions, regards them, however, as having a certain utility. Schreiber, on the other hand, denies that

these inunctions are of any great benefit, and reserves them for special cases only. Mezger favors the use in nearly all cases of inunctions with some fatty substance, to which he would add some essential oil of agreeable odor.

I shall not reproduce here the many formulæ of ointments and pomades employed by the different medicasters. Every professional bone-setter has his particular formula, and, what is a little curious, it is not to the manœuvres which he practises, but to the ointment which he uses, that he attributes the effect obtained. This reminds me of a little incident in my own experience, when I was reporter on secret remedies to the Academy of Medicine. I had my attention called to a certain popular ointment, which was said to cure herniæ. But this is the way that the proprietor ordered it to be used: the hernia must first be rubbed with the ointment, then it was enjoined that a well-fitting truss, sufficient to support the hernia, should be worn after the rubbing. It is so with all these queer pomades which are in use by the different professional "rubbers,"—the inunction has no efficacy unless the accompanying massage is well performed. For my part, I believe that the use of some fat or oil is advantageous in facilitating the movements and passes (*glissements*) of the hand, and I am in the habit of employing vaseline aromatized with an essential oil.

As to the question whether massage should be practised on the denuded skin, Schreiber recommends its performance through a thin flannel wrapper, and, in support of this, appeals to considerations of propriety and modesty. I think, however, with almost all authorities who have had to do with this subject, that massage ought to be practised on the naked body.

We come now to the physiological effects determined by massage. These pertain to the functions of the skin and muscles, to the circulation, nervous system, to absorption, and nutrition.

As for the cutaneous functions, energetic frictions rid the skin of the debris of epidermis by which it is encumbered. The orifices of the sudoriparous and sebaceous glands are cleared, and this facilitates the more regular and thorough performance of the circulatory functions, and respiration of the skin.

The action on the muscles is quite as marked, and by kneadings or strokings of the muscles we arouse and augment their contractility. Strike with the inner border of your hand the triceps cruralis, or the biceps,

and you will see produced on the parts of the muscle thus stroked a peculiar hard swelling, which results from its limited contraction. In certain pathological cases, where the adynamia is profound, as in typhoid fever, this cord-like swelling persists a long time. We have here a fact which well shows the local action of massage on muscular contractility.

Massage acts not only on the deep circulation, but also on the circulation of the muscles and skin. It is by kneadings and pressures that we influence the deep circulation, while it is by slappings and flagellations that we promote a greater activity of the cutaneous circulation, and all you have to do is to stroke a part with the open palm repeatedly to obtain over the parts thus smitten a redness of considerable intensity.

This enhanced activity imparted to the circulation entails an augmentation in its local and general temperature.

As for the local temperature, Mosengeil estimates the heat-rise by massage at 2° and even 3° C. Berné* places it at even a higher figure, and affirms that the rise in the local temperature may attain 5° C. The average, according to him, is $1\frac{1}{4}^{\circ}$ C.

The action on the nervous system is two-fold, and this point claims our attention for a moment, for massage has been very much vaunted in the treatment of neuralgias. Massage, and, in particular, deep pressures and kneadings, produce traction and stretching of the nerve-filaments. Hégart† has endeavored to demonstrate experimentally the elongation of nerves under the influence of the manœuvres of massage, and particularly of movements of flexion of the vertebral column.

Another action of massage on the nervous system is more difficult of explanation. I refer to the strange nervous effects produced by light rubbing (*effleurement*) of the skin, and which are described by some writers under the name of *magnetic passes*. You will find in the recent work of Baréty‡ a description of the effects of these passes, which he calls *neurisation*. This quite special effect of certain practices of massage, although still badly understood, must, nevertheless, be taken into account in estimating the results

which are obtained from these movements in the treatment of certain affections of the nervous system.

But probably the most important action of massage is that which it exercises on the absorption of certain effusions, whether hemorrhagic or inflammatory. Numerous experiments in physiology have been undertaken to explain this resolvent action.

For instance, Mosengeil, in injecting into the knee-joints of hares solutions of Chinese ink, has shown that when the joint is treated by massage, the Chinese ink which has been injected into the joints diffuses itself through the neighboring parts, and that this phenomenon is the more marked the longer the massage is continued. Moreover, Reibmayr and Höfinger have shown that when liquid is injected into the peritoneum of a hare, it is absorbed with greater rapidity if massage is practised. The following table, which I borrow from these experimenters, shows this quite peculiar local action of massage :

Duration.	Liquid absorbed per kilogramme of the subject,		
	Without massage.	With massage.	Difference in favor of massage.
During the first hour....	0.457	0.905	+ 0.452
During the second hour.	0.283	0.120	— 0.163
End of second hour.....	0.740	1.029	+ 0.289

In Sweden and in Germany, as you are aware, it is taught that the living cell is situated in a liquid atmosphere, to which is given the name of *parenchymatous juice*. It is by acting on this parenchymatous juice and on the lymph-spaces that, according to Loven, we are to explain the resolvent action of massage in inflammatory and periarticular affections.

Lastly, massage has an undoubted action on nutrition. It has, in fact, been demonstrated that the quantity of urea in the urine augments under the influence of general massage.

Gopadze has even affirmed that the assimilation of azotized substances is rendered more active by massage. In a series of experiments made on four medical students who were subjected to a special dietary regimen, the nitrogen being estimated both in the aliments and in the dejections, a general massage of twenty-five minutes, made once a day, three hours after the principal meal, caused a diminution in the amount of azotized matters contained in the fæces. From this the experimenter concluded that the assimilation of azotized matters was augmented.

This increased activity imparted to the di-

* Berné, "Researches on the Modifications of the Local Temperature under the Influence of Massage" (*Société Medico-Pratique*, 1885).

† Hégart, *Wiener Med. Blätter*, 1884.

‡ Baréty, "Animal Magnetism studied under the Name of Neuric Force," etc. Paris, 1887.

gestive and assimilative functions by massage has also been affirmed by a young Russian physician, Chpolinski, who, in his inaugural thesis, published last year, "*On the Length of Time that Aliments ordinarily Sojourn in the Stomach*," has shown that the massage of the stomachal region, practised for ten minutes at a time, will diminish the length of the sojourn of food in the stomach.

The first case on which he experimented was that of a medical student, in whom a meal consisting of five hundred grammes of meat was five hours and twenty-five minutes in completely disappearing from the stomach. The days when massage was performed the duration of gastric digestion was only four hours and thirty minutes.

In another subject, where a meal composed of two eggs and a gramme of salt required three hours and fifteen minutes for its disappearance from the stomach, massage reduced this period to two hours and forty-five minutes.

As you see, gentlemen, massage notably promotes the gastric digestion, or at least the passage of alimentary substances from the stomach into the intestine.

One of my pupils, Dr. Hirschberg, has taken up this question anew by some experiments which he has made in my laboratory, which have confirmed the data established by Chpolinski.

Taking for his basis a peculiar property which salol possesses of undergoing decomposition into salicylic acid only in an alkaline medium, Ewald had shown that we can utilize this reaction to ascertain the duration of the sojourn of aliments in the stomach. All you have to do is to test the urine for salicylic acid in individuals to whom salol has been given along with food; the more tardy the appearance of this acid, the longer will be the sojourn of the food in the stomach. In employing this reagent, Hirschberg shows that massage hastens this transformation, and that while in the ordinary state it takes two hours for salicylic acid to appear in the urine, forty minutes suffice after an abdominal massage.

These experiments have, moreover, brought to view a fact which physiologists who have taken up the subject of massage have touched lightly, and which at the same time seems to me to have capital importance in these applications of massotherapy: I refer to the augmentation of diuresis under the influence of abdominal massage. All our patients on whom abdominal massage has been practised have testified to a notable augmentation in the

urine, which sometimes amounts to double the normal quantity, and this is an important point, to which I propose to return when we come to study the indications for massotherapy.

Now that you know the manœuvres of massage (which, in fact, are not at all difficult), and the physiological effects which may be expected therefrom, we may profitably take up the study of the therapeutic applications of massage.

II.

APPLICATIONS OF MASSOTHERAPY.

The applications of massage to therapeutics are numerous. We will, if you please, consider them under several heads, and will successively speak of massage in its applications to obstetrics, gynæcology, surgery, and medicine.

1. The use of massage in obstetrics dates back from the most ancient times. Among all primitive peoples we find massage employed in the practice of midwifery. If you will refer to works written on the obstetrics of different nations (as for instance the familiar treatise of Corre), you will see that almost all the odd methods put in usage are only various forms of massage.

By massage four results are obtained,—(a) the contractions of the uterus are excited; (b) vicious positions are rectified; (c) the placenta is delivered by the process called *expression* (Credé's method); (d) hemorrhages are arrested. To-day all these manœuvres are well known, and give, as you know, excellent results.

Massage of the gravid uterus is made by circular passes over the abdomen. Under some circumstances bimanual massage is of great utility,—i.e., one hand is introduced into the uterine cavity, while the other endeavors by abdominal frictions to excite uterine contractions. This latter manœuvre is principally put in usage in cases of post-partum hemorrhages.

2. In gynæcology it is Norström who has shown himself the most ardent inculcator of massage, which one of his fellow-countrymen, Thure Brandt, a man who, by the way, had no knowledge of medicine, was the first to suggest for the cure of uterine affections. The practice of the Swedish empiric dates from 1868. Thure Brandt recommends three processes of massage, one of which he calls *external massage*, and which consists in rubbing and kneading the abdominal parietes, through which the operator seeks to plunge

his fingers deeply, and, if possible, into the pelvic cavity.

The other process is called *mixed massage*. The patient is placed on her back, and the masseur, taking his position at her left, compresses the uterus with the right hand upon the index and middle finger of the left hand introduced into the vagina; in certain cases, even, the fingers are introduced into the rectum. But the process to which Thure Brandt gives the preference is that which he calls *combined massage*, and which I shall rather call *massage with four hands*; and this is the way that this strange method is put in practice, demanding, as it does, two operators:

One of the masseurs, taking his position between the legs of the patient, introduces the fingers of the left hand into the vagina and raises the uterus, while, with the right hand placed under the hips, he kneads the sacro-lumbalis muscles. The other masseur operates on the abdominal parietes, and associating and giving a rhythmical character to their manœuvres, the two practitioners devote themselves to rubbings, tractions, and kneadings of all sorts.

One cannot too strongly condemn such practices, and my pupil, Dr. Leon Petit, in his communication on "Massage of the Uterus," made to the Society of Practical Medicine,* has well shown how useless and how dangerous are such manœuvres, which belong rather to the domain of onanism than to that of therapeutics. So, notwithstanding the facts cited by the advocates of uterine massage, and in particular by Reeves Jackson, of New York, and Norström, of Paris, I pray you never to employ such methods.

Besides all the moral drawbacks which result from this handling and rubbing of the genital parts, and of which I need say no more, there is a rule which is imperative in almost all uterine affections, viz., rest of the organ is indispensable. My master, Bernutz, has justly insisted on this fact, that in most uterine maladies it is rest of the organ and function which brings about the cure, and it is a violation of this rule to introduce the hand into the vagina, and thereby exercise pressures or frictions, which, however light they may be, tend to excite and congest the genitals. Therefore, notwithstanding the sixteen favorable observations recently published

by Paul Profanter,† where massage applied to the treatment of displacements and of prolapsus, as well as of uterine and periuterine engorgements, has resulted in cure, I persist in believing that this method has more of evil than of advantage in the treatment of these affections, and I pass now to the application of massage to surgery.

3. I shall be brief on these surgical applications, and shall concern myself particularly with the treatment of sprains by massage. I ought to remind you, however, that massage, heretofore reserved in surgery for the joint-diseases, has been applied the last few years to the treatment of fractures, and this has been done under the influence of Schode of Hamburg, of Menzel of Trieste, of Mezger and Tilanus of Amsterdam, and especially of Lucas-Championnière, who, in July, 1866, communicated to the Society of Surgery the successful results which had been obtained in fractures by massage. Berne, who was one of the first in France to recommend massage in the treatment of fractures, and whose writings are even anterior to those of Lucas-Championnière, considers fractures of the radius and of the fibula at their lower extremities, also those of the elbow and patella, as especially tributary to this method. He regards the application of a splint which can be easily removed at the moment of massage, as more useful than any permanent fixture, because presenting no impediment to the prompt return of the functions of the joint.‡

Quite recently, moreover, Prof. Masse of Bordeaux§ has taken up the subject again, and pointed out all the benefits derivable from massotherapy in counteracting the disastrous effects of immobilization as imposed by the retentive apparatuses hitherto applied in these cases.

The treatment of **SPRAINS** by massage has been attended with excellent results. First practised by the bone-setters, gray nuns, "sprain-blowers" (*souffleurs d'entorses*), etc., massage is to-day employed in the treatment of sprain by all surgeons, and the works of Ellaume, of Lebatard, of Mervy, of Estradère, of Rizet, etc., show us the importance of this method.

† Paul Profanter, "On Massage in Gynæcology" (*Wien.*, 1887).

‡ Berne, "On the Technics of the Treatment of Fractures by Massage" (*Revue Gen. de Clin. et de Thér.*, June, 1887).

§ Masse, "On the Treatment of Fractures by Massage" (*Gaz. Hebdom. des Soc. Méd. de Bordeaux*, July 3, 1887).

* Leon Petit, "On Massage of the Uterus in Obstetrics and Gynæcology" (*Journal de Médecine de Paris*, May 16, 1886).

All cases of sprain, simple or complicated, except, of course, those where there exists a fracture of the joints (and we have seen that even this is not now regarded as a contra-indication), are tributary to massage. The beneficial effects are the more speedy and the more certain the sooner massage is applied after the accident, and you will often see patients who at first could not stand on their feet get up and walk, and even return to their homes on foot, after their first séance of massage.

But it is necessary to be exact in the diagnosis, and this it is that explains the reason of the successes and the failures of the bone-setters, who apply massage to all the traumatisms of the joints, whether these pertain to sprain or to white swelling. In the case of sprain, marvellous results are easily obtained, while in white swelling only disastrous consequences would ensue from massage.

You ought, then, gentlemen, to understand well all the manœuvres of massage in sprains. All that have been counselled thus far may be summed up in three processes,—those of Lebatard, of Gerard, and of Magne.

In the process of Lebatard, the masseur seizes the heel of the extremity which is the seat of the sprain with the palm of the opposite hand; then he makes with the foot a seesaw motion back and forth, while exercising a strong traction on the tendo-Achillis. In this manipulation the thumb is made to grasp as far as possible the tibio-tarsal swelling, while the endeavor is made to force behind the external malleolus all the swollen parts. The opposite hand executes similar movements over the internal malleolus; then, when the malleoli have recovered their natural form, the fingers seek by pressures over the tendo-Achillis to free that tendon.

Gerard's method is less harsh than that of Lebatard. It consists in light rubbings (*effleuréments*) with the tips of the fingers. After ten or fifteen minutes the operator passes to the second stage, which comprehends a kneading of the peri-malleolar parts; this is made from below upward, from the tips of the toes to the upper third of the tibia. Then the massage is completed by a few flexions and extensions of the joint.

Magne's process, adopted by Estradère, is intermediary between the other two. The operator commences by frictions, the intensity of which is gradually augmented. At the end of thirty or forty minutes, he exercises the joint after the manner of Lebatard, then he finishes by a massage of fifteen or

twenty minutes. The total duration of the operation is nearly two hours.

As you see, gentlemen, the massage of sprains is very simple, demanding of the physician first an accurate diagnosis, then energy, then patience.

Busch, who in Ziemssen's Hand-book has given a good monograph on massage, considers that in sprains these manipulations fulfil the three following ends: First, they restore the parts to their natural situation, and in this connection he refers to the practice of one of our surgeons, Ravaton, who, in cases of sprain, has two stout men pull apart the articular surfaces, while the hands of the surgeon are clasped tightly around the joint thus stretched. The second effect of massage is to lessen and abate the muscular spasm which always accompanies the articular distortion. Here kneadings of the muscles act the most effectually in antagonizing this spasmodic state. The third result obtained by massage consists in the disappearance of the blood-effusion which attends sprains; the absorption and removal of this effusion is promoted by the rubbings, which are made from the extremity of the member to its base.

As for the results thus far gained, statistics are most favorable, and in those which have been published by Mullier and Moller, it appears that while immobilization and ice will bring about the cure of a sprain in an average of twenty-five days, massage well performed will accomplish this result in an average of nine days.

In the Prussian army, where massage is obligatory in a certain number of affections, and, in particular, in sprains, the military surgeons, in their half-yearly reports, do not fail to communicate the results obtained by this method. By referring to the reports of Starke, Gassner, Brurberger, Gerst, and Korner, you will see that the average duration of the disability entailed by sprains, where massage has not been employed, is 27.3 days, and where massage has been used 8.9 days, so that you see there is a difference of 14.8 days in favor of the treatment of sprains by massage. It is to be wished that the same practice might be obligatory on the military surgeons of our army. I ought here to remark, however, that my friend and colleague, Marc Sée, considers compression made with an elastic bandage, in the case of sprains, superior in its results to massage.*

* Marc Sée, "On Sprain and its Treatment." Paris, 1884.

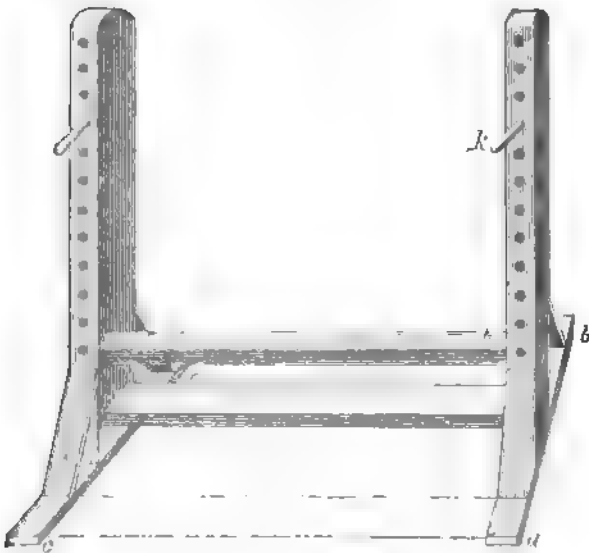

4. I come now to the medical applications of massage. These are very numerous, and we will, if you please, divide them into several groups. I will speak, first, of massage in the treatment of pain, then in articular and muscular affections, then in neuroses, and, lastly, in certain visceral affections.

As I have before told you, it is by an instinctive movement that man seeks to relieve pain by frictions, and I have often seen patients in the agonies of *tic douloureux* rub the skin till abrasion and bleeding were produced. Experts have given regularity and system to these practices, and what I have to say on this head shall pertain particularly to sciatica and migraine.

It is Schreiber* who has given us the most precise rules as to the treatment of sciatica by massage. The treatment of sciatica, according to Schreiber, consists in massage, the application of certain apparatuses, and in passive movements.

The apparatus consists of a frame, of a mechanical bed, and of several short joists.

FIG. 1.

The frame is a very simple affair, and is composed of two uprights pierced with holes, which enable one to elevate to variable heights a horizontal bar (*g, h*). (See Fig. 1.) As for the mechanical bed (Fig. 2), it is also of Schreiber's invention, and is of simple construction. It is composed, as you see, of different segments, which are raised or lowered at will by means of ratchets. The patient is placed on the bed, as is shown in Fig. 3. As for the joists, they are one metre long,

six centimetres thick, and twelve centimetres wide.

This is the way these means are utilized, along with massage, in the treatment of sciatica. I shall not follow Schreiber in the enumeration of all the manoeuvres, day by day up to the thirty-second day, which are prescribed by that authority, but shall only give a rapid sketch of his method.

The first day the patient is placed before the frame, and the horizontal wooden bar being placed as low as possible in the two uprights, by adjusting the pins (*k*), the patient is directed to extend the foot of the affected limb upon the transverse bar, holding on to the two uprights by his hands. This manoeuvre is repeated ten times.

Then the patient is placed on the mechanical bed, as is seen in Fig. 3, and passive movements are executed, which consist in flexing the thighs on the body and elevating the leg on the thigh; these movements are repeated twenty times. Lastly, a gentle massage is practised, which consists the first day in simple light rubbings over the painful points.

The second day these manoeuvres are repeated, especial attention being given to massage, and kneading of the muscles is then begun. Passive movements also are performed; the thigh is moved back and forth from the middle line.

Then the following days the movements are progressively increased, and the horizontal bar of the frame is gradually raised by putting it into the higher sockets, so that the patient is obliged every day to attain with the foot a greater height.

At the end of the first week the exercises with the little posts are commenced. These are placed on the ground at regular intervals (like nine-pins), and the patient is made to walk between them without hitting them with his feet.

Lastly, the passive movements are performed by rotating the affected thigh in its joint.

Such is the mechanotherapy and the massotherapy treatment of Schreiber. It is, as you see, somewhat complicated and lengthy, and is only applicable to cases of sciatica which are stubborn,—i.e., to those which have resisted punctiform cauterizations and the methyl spray. In such cases as these I cannot too much recommend Schreiber's method.

This practice of massage is applicable to all the other neuralgias, but the manoeuvres are variable, according to the seat of pain, and among these painful affections I must

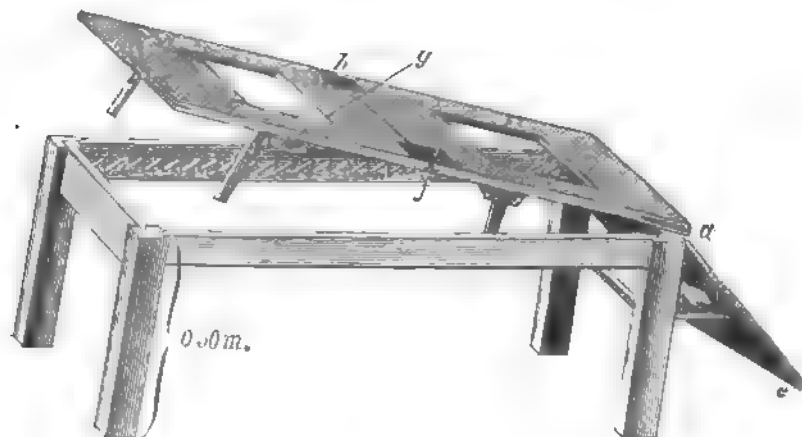

* See his book on "Massage," recently published by Lea, Philadelphia.

point out to you in particular the good effects of massage in the treatment of migraine. Here it is principally the muscles of the head which are treated by massage, which is performed with the pulps of the fingers; this is the *pulpation* of Laisné, which consists of a series of taps made over different points of

arthritis, periarticular engorgements, chronic synovitis, chronic rheumatism under all its forms, are tributary to treatment by massage.

It is well understood that massotherapy must not be employed till at an advanced period of the disease, when all the acute inflammatory symptoms have subsided. Danger-

FIG. 2.

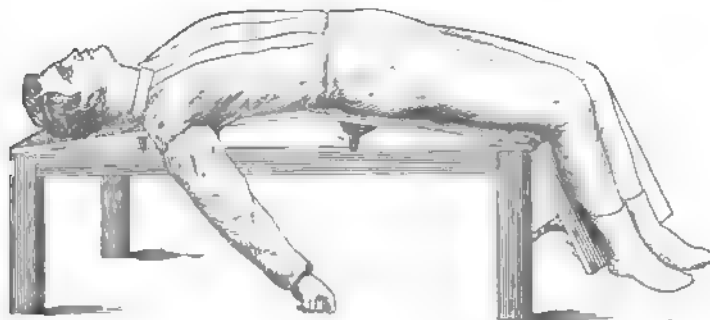

the head, just as if one was playing on a piano. A certain dexterity is required in executing this manoeuvre, which, if we may trust the trials made by Romberg, by Dubois-Reymond, and especially by Dr. Weiss, gives excellent results.

Lucas Pardington has, moreover, quite recently taken up the subject of treatment of migraine by massage, and he has reported a case of a man, 26 years of age, suffering from hemicrania of grave form and rebellious to all the means of treatment, which was

ous as it is to practise massage on a joint which is the seat of an intense acute inflammation, there is no disputing the advantage which such massage can confer on joints when the acute symptoms have disappeared, and you can see at any time in our hospital wards the remarkable results obtained from massage by our clinical assistant, M^{lle}. Chappat, in the treatment of the sequelæ of rheumatism, generally so long and painful. Here the action of massage is twofold. It not only restores movement to the joint, but it promotes reso-

FIG. 3.

cured in three days by séances of massage of twenty minutes' duration made over all points of the head and neck which were affected.*

As for the articular affections, it may be affirmed that all kinds of stiff joints, chronic

lution and disappearance of engorgements and periarticular adhesions.

The manipulations vary according to the joints affected, but all have this end,—gradually to restore the movements of the joint on the one hand, and the natural form of the joint on the other.

It is the same with the muscular affections,

* Pardington, "On the Treatment of Migraine by Massage" (*The Practitioner*, 1887).

—atrophy and contracture. In these cases massage is superior to gymnastics.

In his interesting monograph on massage, William Murrell calls particular attention to the benefits which may be derived from massage in infantile paralysis, locomotor ataxia, and in writer's cramp.

Wolf, of Frankfort-on-the-Main, was the first to lay down the rules of treatment of writer's cramp by massage. Wolf is not a physician, but a professor of gymnastics. The method which he urges consists of massage and gymnastic manœuvres. His favorite massage movements are principally frictions and digital taps. The gymnastics which he advises are both active and passive, the former consisting in sudden movements, which the patients execute with the hands, which are now opened and now shut, and which are kept up for half an hour; these exercises are repeated three times a day. The passive movements consist in the forced distention, or rather elongation, of the muscles of the fore-arm. This elongation is done by the patient himself, who repeats it three or four hundred times a day. If we may believe Romain Vigouroux,* this treatment causes writer's cramp to disappear in a fortnight.

I will add that for the symptom cramp, whatever may be its cause, massage is a sovereign remedy, and you should here employ principally kneading of the muscles and the strokes or taps (*tapotement*).

Paralysis agitans is also believed to be amenable to treatment by massage, and Berbès has recently reported to the Society of Therapeutics the favorable results which he has obtained by this means in a case of Parkinson's disease.†

As for the neuroses, I shall not repeat what I have said *à propos* of the treatment of chorea by gymnastics, where, in truth, massage is oftener employed than gymnastics properly so called, but I must call your especial attention to massage in hysteria, because serving as the basis of a kind of treatment of this disease which has become very popular of late years under the name of S. Weir Mitchell's method. This mode of treatment is complex, and demands for its execution the isolation of the patient, absolute repose, and the employment of massage and electricity.

Dr. S. Weir Mitchell begins by completely

isolating his hysterical patients from their family and usual surroundings, and putting them under the care of a trained nurse, who never leaves them; then he subjects them to absolute repose and a special diet system, of which milk and eggs form the basis. Then he insists on the application of general massage, and sometimes of electricity, which plays, however, but a secondary rôle in the treatment, as the movements produced thereby only serve to combat the disastrous effects of immobility. This treatment has had but few advocates in France, and it is hardly applicable except to extreme cases of hysteria. Nothing shows that it is superior to the treatment which we employ in such cases,—isolation, hydrotherapy, and exercise in the open air. I shall, however, return to all these points in one of my future lectures on hydrotherapy.

It remains for me to say a few words concerning massage in general affections. In diseases of the heart, massage will render you service in combating œdema, and the same may be said of œdema due to renal affections; and I remember to have seen a remarkable example of this. The patient was the wife of a medical *confrère*, who was suffering from albuminous nephritis, with considerable anasarca of the lower limbs, which doomed her to absolute rest. Massage removed the œdema, which did not return, although the quantity of albumen in the urine remained unchanged.

Here the effects of massage are twofold. It acts, first of all, locally, and favors the resorption of effused liquids; then it has a general action, promoting nutrition, augmenting the excretion of urea, and thus combating one of the effects of chronic alterations of the kidneys.

Furthermore, I showed you, while speaking of the physiological action of massage, that the practice of abdominal massage notably augments the excretion of urine. This is an effect which ought to be taken account of in explaining the favorable effects of massage in cardiac and renal affections.

Lastly, in abdominal affections, constipation, and dilatation of the stomach, massage has been found to give excellent results. When, in fact, you study the physiological observations of Chpolianski and of Gopadze, you see that by massage the assimilative functions of the digestive tube are promoted, and the passage of the alimentary bolus is favored. Clinical observations give support to the facts testified to by physiology.

As for constipation, everybody is agreed in

* Romain Vigouroux, "On the Treatment of Writer's Cramp by Wolf's Method" (*Progrès Médical*, January 21, 1882).

† Berbès, Soc. de Thé., Session June 8, 1887.

acknowledging the good results obtained by massage. Berne,* who has so urged the importance of abdominal massage, recommends the following mode of procedure: After having kneaded the abdominal teguments, then the abdominal muscles, the operator makes gentle pressure over the cæcal region with the palmar extremities of the last four fingers; then, with the closed fists, he performs massage over the whole extent of the colon. Berne insists that this massage shall be both very gentle and very deep. He recommends, moreover, that the patient should be made to urinate before massage, and that careful examination should be made to see if there be any tumors in the abdomen, or any calculus in the gall-bladder. The length of each séance should be fifteen or twenty minutes. Besides insisting on the mechanical action of massage, Berne makes great account of the property which these exercises possess in promoting the secretion of bile. Hence he advises to associate with the above-mentioned manœuvres gentle pressures over the gall-bladder.

As for the application of massage to the affections of the stomach, and in particular to dilatation of the stomach, massage in these cases gives excellent results. For more than a month past you have seen in our hospital wards Dr. Hirschberg practise massage on the greater part of our patients who are suffering from dilatation of the stomach. You have been enabled to witness the marked benefits which these patients have derived therefrom; their digestion is improved, their weight is augmented, the *clapement* and all the distressing symptoms are alleviated. It is, then, a practice which you ought to resort to in such cases.

Such are, rapidly summarized, the hints that I wish to give you respecting massage. I believe that these suggestions will be of value to you, and that you will be able to turn them to account in your future practice. For my part I have never ceased to felicitate myself on the use which I have made of massage.

In the next lecture we will undertake the study of one of the most powerful agents of hygienic therapeutics, often put in practice along with gymnastics and massotherapy: I refer to hydrotherapy.

* Berne, "Treatment of Constipation by Massage." Paris, 1887.

DITANA DIGITIFOLIA.

By H. H. RUSBY, M.D., DETROIT, MICH.

WE are told that in 1870 Prof. Westore Giurleo received from a friend, an Italian chemist, then residing in Mexico, the flowers of a plant whose habitat was said to be Virginia. On account of the peculiar construction of the leaf the plant was called *Ditana digitifolia*. Experiment with the drug, with reference to its therapeutic value, disclosed the fact that it possessed valuable galactagogue properties, as by its internal "application" the secretion of the milk could be perceptibly increased. Thorough investigation could not be made on account of the scarcity of material at hand. Prof. Giurleo, however, read a paper on the subject of this plant and its properties, under the name of *Ditana digitifolia*, before the Italian Medical Congress of Perugia, by which means he succeeded in getting the drug before the reputable physicians of Europe, and secured notices in the medical press, the name *Ditana digitifolia* always being used. An abstract of his paper was printed in *Il Morgagni*, parte 11, 44, 1885. This article afterwards reappeared in the *Deutsche Medicinal Zeitung*, and was from time to time noticed in many other journals. In this country it was briefly referred to in the THERAPEUTIC GAZETTE, *The Chicago Med. News*, and the *N. Y. Med. Journal*. The *Med. News* says, "The professor has apparently been misled, as no one but himself has been able to find the plant." The *Med. Journal* considers that *Ditana digitifolia* is a synonyme for *Rhamnus alaternus* L.

Mr. Thomas Christy desiring to obtain supplies of the drug, wrote to his agent in Mexico, enclosing a drawing of the plant, copied from an advertisement of a patent medicine claiming to be made therefrom. His agent replied that he had been unable to obtain any information in regard to it, but that, judging from the drawing, it belonged in the family Onagraceæ, the flowers having the form of *Zauschneria*. Mr. Christy then applied directly to Giurleo, but his communication was unnoticed. Messrs. Parke, Davis & Co., taking the investigation in hand, after vainly exhausting every other source of possible information, wrote to Prof. Giurleo, urging that he should satisfy the growing inquiry regarding this name. In reply they received a supply of quack advertisements, with a label printed in four languages, in which Giurleo sets forth that the remarkable remedy "Ga-

lattoforo," "invented by him," is already recommended by all the leading therapeutists, and "all people," he says, "ask it above all for its perfection, good taste, and prodigious virtue." He then furnishes popular directions for its use, appeals to the public to purchase directly from himself, "the inventor," and concludes by stating that orders unaccompanied by cash are worthless, an announcement which appears to be quite necessary in the Mediterranean countries. Accompanying is a little pamphlet for public distribution filled with popular testimonials. As a frontispiece we have a picture of a fond mother viewing her children playing in the shade of the wonderful plant, whose single terminal flower appears to be more than eighteen inches in length,—looks like a gigantic fuchsia. On page 4 is a second cut of the plant, which differs considerably from that in the frontispiece, having apparently been constructed to indicate how much more like a kid glove the "inventor" could have made the leaves than nature has done.

Such is the information that we have been able to secure concerning *Ditana digitifolia* and its proprietary product Galattoforo. From it we deduce the following conclusions:

1. *Ditana digitifolia* means nothing. It is not a botanical name, as it has never been accompanied by any description, and the originator has even been ashamed to append his name as authority. It will never be admitted into any botanical work. The *Medical Journal* is in error in supposing it to be a synonyme for *Rhamnus alaternus* L., as the little that has been published rather contrasts the two plants as being antagonistic in their action.

2. The plant represented by Prof. Giurleo under this name is a botanical impossibility. Its leaves exclude it from the family Onagraceæ; but, aside from this, the whole figure is a monstrosity, and that on page 4 of the pamphlet carries on its face the evidence of fraud, in the manner in which it has been doctored, to produce a sensational effect.

3. Further evidences of fraud are found in the attempt to mislead the public into the belief that the plant is unknown, or has no other name than the fanciful one above referred to. The eighteen years during which the professor has been receiving supplies for the manufacture of his quack medicine has afforded ample opportunities for securing material for botanical identification if it were a known plant. If, on the contrary, it were unknown, it should

have been referred to some competent botanist for classification and publication. Under the circumstances, we are perfectly justified in assuming that the whole thing is scientifically a swindle from beginning to end, and that the origin of Galattoforo may as well be a door-yard weed from the vicinity of Rome as some mysterious plant from Mexico.

Lastly, and what is of the greatest importance for us to consider, there is no doubt that numbers of sincere people, especially in Europe, have been deceived and misled by this man, who appears to have enjoyed heretofore some degree of reputation. Their error has been that of accepting a name unaccompanied by its authority. It is a cardinal rule among botanists to append the name of the author of a species in every case where the name is written, unless it may occur several times in the course of a single article. This rule has not been generally recognized by the medical press, particularly in the United States. In just so far as they have failed to do so they have been unscientific, and in a most important particular, for it is certain that in a large majority of cases such errors and deceptions creep in through a failure to observe this judicious regulation. If Prof. Giurleo does not wish to be ranked among charlatans he must tell us the truth about *Ditana digitifolia*.

OXYGEN ENEMATA.

By J. H. KELLOGG, M.D., BATTLE CREEK, MICH.

SOME weeks ago, while employing the carbon-dioxide and sulphuretted hydrogen enemata, it occurred to me that oxygen gas might be employed advantageously in the same manner. Having at that time under treatment a case of lithiasis, I resolved to make a trial of the administration of oxygen by enema, in the hope that by the introduction of oxygen directly into the portal circulation the conversion of uric acid into urea might be aided, and my patient thereby relieved. I was at first deterred from the attempt by the supposition that oxygen would probably give pain, as it has been claimed that the pain sometimes occasioned in the employment of sulphuretted hydrogen by the Bergeon method is produced by the accidental injection of small quantities of atmospheric air. I determined, however, to try the experiment, and made the first injec-

tion of two litres of pure oxygen gas on June 20. At this time the patient, a man of 28 years, was passing very great quantities of uric acid daily, a large quantity of crystals being thrown down from every specimen of urine passed. The symptom had persisted most stubbornly for weeks in spite of the enforcement of a non-nitrogenous diet, the patient also taking by direction from three to five pints of hot water daily. The beneficial effect of either regimen or treatment was so slight as to be scarcely perceptible. Two litres of oxygen were administered regularly each day about 10 A.M. At the end of three days the excess of uric acid disappeared entirely from the urine, and has appeared only twice since, and then in small quantity, when the injection had been discontinued for a day or two. At the beginning of treatment the patient's skin was very muddy, sclerotics dingy, tongue coated, and he complained of a constant and very annoying brassy taste in the mouth and distressing headache. The brassy taste and headache both disappeared very soon after the injections were begun, and there has been a steady improvement in every other particular. The coat has disappeared from the tongue, the skin and sclerotics have become nearly normal in appearance, and the patient has gained several pounds in weight, though before he had been constantly losing weight for some weeks, and seems to be in every respect improved. The patient, a very intelligent gentleman, attributes his improvement almost wholly to the employment of the oxygen, as the measures which had been previously employed had had little or no favorable influence upon his condition, and no change in regimen or treatment has been made with the exception of the administration of the oxygen. It seems to the writer that there may be a large field of usefulness for oxygen employed after this method. The advantages of the employment of oxygen by enema, as compared with the inhalation of oxygen, are very great.

1. In the inhalation of oxygen only a very small portion of the gas inhaled can be used, the greater part being wasted, as experiment has shown that not more than one-fourth of the oxygen contained in the air is extracted by the lungs during the passage of the air through them in ordinary respiration, and that a very much smaller proportion is absorbed when the quantity of air passing through the lungs is increased, as in deep breathing. Hence, in order to get into the system any considerable quantity of oxygen,

it is necessary for a person to inhale a very large amount, making the treatment very expensive.

2. Experiments which have been made for the purpose of testing the therapeutic value of oxygen inhalations have shown that the proportion of oxygen absorbed by the lungs is not proportionally increased by the increase of the percentage of oxygen in the respired air. Indeed, the reported results of careful experiments show that very little more oxygen was actually received by the system when breathing pure oxygen than in the breathing of ordinary atmospheric air. When oxygen is introduced into the alimentary canal the entire quantity introduced is absorbed, and thus utilized, making it possible to introduce a known quantity of oxygen into the system, and in a manner which leaves no room for doubt that it has been received and appropriated.

3. In cases in which it may be considered desirable that a considerable quantity of oxygen should be introduced into the system for the purpose of encouraging the oxidation processes by which effete matters are disintegrated and prepared for alimentation, especially those which are acted upon by the liver, the oxygen enema offers a means by which the gas can be applied where it is most needed. Oxygen received by the lungs passes at once to the left side of the heart, and thence through the arterial system to the entire body, so that the liver receives no more than its due proportion of the gas. Consequently, a very considerable increase in the quantity of oxygen absorbed through the lungs would scarcely increase to an appreciable degree the amount of oxygen available for use by the liver. This fact is made particularly conspicuous when we reflect that the chief source of blood-supply to the liver is the portal circulation. It is apparent, however, that when oxygen is introduced into the lower part of the alimentary canal, it is at once received through the venous absorbents into the portal circulation, through which it is conveyed directly to the liver, precisely where it is needed, thus making the entire amount of oxygen administered available for the purpose for which it is administered. Is it not, then, apparent that this method of administering oxygen possesses, for cases of the sort referred to, an immense advantage over its use by inhalation?

4. The process of digestion is, from a chemical stand-point, chiefly a process of hydration and oxidation. The experiments

of Dujardin-Beaumetz, performed some time ago, showed that the drinking of oxygenated water exerts a very beneficial effect upon the digestive process in persons suffering with slow digestion. (I have not seen any extended account of experiments of Dujardin-Beaumetz; I have simply seen in medical literature a mention of the fact stated.) May it not be true that, in some cases at least, the difficulty under which the digestive organs labor is a lack of a sufficient supply of oxygen in the blood, or, at any rate, that the introduction of oxygen into the portal circulation by oxygen enemata may be found to facilitate the digestive process? It is very easy to make a practical test of the matter, and I am now engaged in a series of experiments in the use of oxygen in various forms of dyspepsia, the results of which I shall report at some future time.

5. It seems to me that oxygen enemata may be employed advantageously in a great variety of cases; in fact, in all cases in which there is such a disturbance of the normal interchange of gases in the lungs as deprives the system of its proper amount of oxygen. The mucous membrane of the intestines presents an absorbing surface; very small, it is true, when compared with the amount of surface presented to the air in the lungs, and yet it is sufficiently great to allow of the introduction into the system of a large amount of oxygen in addition to that which can be gotten in through the lungs; and this additional quantity, though small when compared with the total amount received by the lungs, may be of sufficient value to the system to be of immense advantage to it, especially on account of its introduction at this particular point in the circulation. The notable functional disturbances of the stomach which accompany various pulmonary disorders, such as emphysema, chronic bronchial catarrh, chronic pleurisy, pneumothorax, etc., suggest a very important relation between the digestive function and the quantity of oxygen received through the lungs. The same relation is also suggested by the frequency with which dyspepsia occurs among sedentary persons, who are habitually air-starved in consequence of deficient muscular activity. Oxygen enemata may prove a valuable remedy in cases of this sort, as well as in others in which an additional supply of oxygen is needed.

I have carefully questioned patients respecting the retention of the oxygen injected, and have found that it has always been retained without difficulty, and does not pass

off as flatus from the bowels or eructations from the stomach. This fact offers good evidence of its absorption, but to determine the fact beyond the possibility of question, I made on July 20 an experiment on a guinea-pig. After placing the animal under chloroform, the abdomen was opened, and the intestines drawn out and spread out in such a way that the dark portal veins were in full view. A quantity of gas was then injected into the rectum, and to my great satisfaction I found that the dark venous blood assumed a bright red hue almost equal to that of arterial blood within less than one minute after the injection of the gas, showing the rapidity with which the absorption of the oxygen takes place. To confirm the result, I allowed the oxygen to escape from the bowels, afterwards replacing it, and repeating the experiment several times. In each instance the color of the blood in the mesenteric veins assumed its ordinary dark purple color immediately after the oxygen was withdrawn, while the bright color returned almost instantly when the new supply of oxygen was introduced. I have been informed by Dr. Hal Wyman, of Detroit, that he made a similar experiment upon dogs a number of years ago, and that he observed the same result as regards the effect of the oxygen on the color of the blood in the portal circulation, but I understand that he made no attempt to employ oxygen in this manner for therapeutic purposes. Indeed, I am not aware that the gas has been used in this manner prior to my own experiment in the case which I have reported. I shall, however, be much surprised if I learn that I am entitled to the credit of priority in this matter, as it seems to me that I must have been very dull not to have sooner thought of this mode of employing so valuable an agent as oxygen.

It has been long known to physiologists that in certain fishes the mucous lining of the alimentary canal performs a very important part of the work of the respiratory system. Some members of the gar family are killed as quickly by cutting off the supply of oxygen to the alimentary canal as by interrupting the gill respiration. Great numbers of illustrations might be given from the lower classes of the animal kingdom in which the entire process of respiration is carried on by the mucous lining of the alimentary canal. Why, then, should not man, whose alimentary canal is very much more extensive and better fitted for absorption than in lower animals, also be able to receive a very appreciable and effi-

tion of two litres of pure oxygen gas on June 20. At this time the patient, a man of 28 years, was passing very great quantities of uric acid daily, a large quantity of crystals being thrown down from every specimen of urine passed. The symptom had persisted most stubbornly for weeks in spite of the enforcement of a non-nitrogenous diet, the patient also taking by direction from three to five pints of hot water daily. The beneficial effect of either regimen or treatment was so slight as to be scarcely perceptible. Two litres of oxygen were administered regularly each day about 10 A.M. At the end of three days the excess of uric acid disappeared entirely from the urine, and has appeared only twice since, and then in small quantity, when the injection had been discontinued for a day or two. At the beginning of treatment the patient's skin was very muddy, sclerotics dingy, tongue coated, and he complained of a constant and very annoying brassy taste in the mouth and distressing headache. The brassy taste and headache both disappeared very soon after the injections were begun, and there has been a steady improvement in every other particular. The coat has disappeared from the tongue, the skin and sclerotics have become nearly normal in appearance, and the patient has gained several pounds in weight, though before he had been constantly losing weight for some weeks, and seems to be in every respect improved. The patient, a very intelligent gentleman, attributes his improvement almost wholly to the employment of the oxygen, as the measures which had been previously employed had had little or no favorable influence upon his condition, and no change in regimen or treatment has been made with the exception of the administration of the oxygen. It seems to the writer that there may be a large field of usefulness for oxygen employed after this method. The advantages of the employment of oxygen by enema, as compared with the inhalation of oxygen, are very great.

1. In the inhalation of oxygen only a very small portion of the gas inhaled can be used, the greater part being wasted, as experiment has shown that not more than one-fourth of the oxygen contained in the air is extracted by the lungs during the passage of the air through them in ordinary respiration, and that a very much smaller proportion is absorbed when the quantity of air passing through the lungs is increased, as in deep breathing. Hence, in order to get into the system any considerable quantity of oxygen,

it is necessary for a person to inhale a very large amount, making the treatment very expensive.

2. Experiments which have been made for the purpose of testing the therapeutic value of oxygen inhalations have shown that the proportion of oxygen absorbed by the lungs is not proportionally increased by the increase of the percentage of oxygen in the respired air. Indeed, the reported results of careful experiments show that very little more oxygen was actually received by the system when breathing pure oxygen than in the breathing of ordinary atmospheric air. When oxygen is introduced into the alimentary canal the entire quantity introduced is absorbed, and thus utilized, making it possible to introduce a known quantity of oxygen into the system, and in a manner which leaves no room for doubt that it has been received and appropriated.

3. In cases in which it may be considered desirable that a considerable quantity of oxygen should be introduced into the system for the purpose of encouraging the oxidation processes by which effete matters are disintegrated and prepared for alimentation, especially those which are acted upon by the liver, the oxygen enema offers a means by which the gas can be applied where it is most needed. Oxygen received by the lungs passes at once to the left side of the heart, and thence through the arterial system to the entire body, so that the liver receives no more than its due proportion of the gas. Consequently, a very considerable increase in the quantity of oxygen absorbed through the lungs would scarcely increase to an appreciable degree the amount of oxygen available for use by the liver. This fact is made particularly conspicuous when we reflect that the chief source of blood-supply to the liver is the portal circulation. It is apparent, however, that when oxygen is introduced into the lower part of the alimentary canal, it is at once received through the venous absorbents into the portal circulation, through which it is conveyed directly to the liver, precisely where it is needed, thus making the entire amount of oxygen administered available for the purpose for which it is administered. Is it not, then, apparent that this method of administering oxygen possesses, for cases of the sort referred to, an immense advantage over its use by inhalation?

4. The process of digestion is, from a chemical stand-point, chiefly a process of hydration and oxidation. The experiments

of Dujardin-Beaumetz, performed some time ago, showed that the drinking of oxygenated water exerts a very beneficial effect upon the digestive process in persons suffering with slow digestion. (I have not seen any extended account of experiments of Dujardin-Beaumetz; I have simply seen in medical literature a mention of the fact stated.) May it not be true that, in some cases at least, the difficulty under which the digestive organs labor is a lack of a sufficient supply of oxygen in the blood, or, at any rate, that the introduction of oxygen into the portal circulation by oxygen enemata may be found to facilitate the digestive process? It is very easy to make a practical test of the matter, and I am now engaged in a series of experiments in the use of oxygen in various forms of dyspepsia, the results of which I shall report at some future time.

5. It seems to me that oxygen enemata may be employed advantageously in a great variety of cases; in fact, in all cases in which there is such a disturbance of the normal interchange of gases in the lungs as deprives the system of its proper amount of oxygen. The mucous membrane of the intestines presents an absorbing surface; very small, it is true, when compared with the amount of surface presented to the air in the lungs, and yet it is sufficiently great to allow of the introduction into the system of a large amount of oxygen in addition to that which can be gotten in through the lungs; and this additional quantity, though small when compared with the total amount received by the lungs, may be of sufficient value to the system to be of immense advantage to it, especially on account of its introduction at this particular point in the circulation. The notable functional disturbances of the stomach which accompany various pulmonary disorders, such as emphysema, chronic bronchial catarrh, chronic pleurisy, pneumothorax, etc., suggest a very important relation between the digestive function and the quantity of oxygen received through the lungs. The same relation is also suggested by the frequency with which dyspepsia occurs among sedentary persons, who are habitually air-starved in consequence of deficient muscular activity. Oxygen enemata may prove a valuable remedy in cases of this sort, as well as in others in which an additional supply of oxygen is needed.

I have carefully questioned patients respecting the retention of the oxygen injected, and have found that it has always been retained without difficulty, and does not pass

off as flatus from the bowels or eructations from the stomach. This fact offers good evidence of its absorption, but to determine the fact beyond the possibility of question, I made on July 20 an experiment on a guinea-pig. After placing the animal under chloroform, the abdomen was opened, and the intestines drawn out and spread out in such a way that the dark portal veins were in full view. A quantity of gas was then injected into the rectum, and to my great satisfaction I found that the dark venous blood assumed a bright red hue almost equal to that of arterial blood within less than one minute after the injection of the gas, showing the rapidity with which the absorption of the oxygen takes place. To confirm the result, I allowed the oxygen to escape from the bowels, afterwards replacing it, and repeating the experiment several times. In each instance the color of the blood in the mesenteric veins assumed its ordinary dark purple color immediately after the oxygen was withdrawn, while the bright color returned almost instantly when the new supply of oxygen was introduced. I have been informed by Dr. Hal Wyman, of Detroit, that he made a similar experiment upon dogs a number of years ago, and that he observed the same result as regards the effect of the oxygen on the color of the blood in the portal circulation, but I understand that he made no attempt to employ oxygen in this manner for therapeutic purposes. Indeed, I am not aware that the gas has been used in this manner prior to my own experiment in the case which I have reported. I shall, however, be much surprised if I learn that I am entitled to the credit of priority in this matter, as it seems to me that I must have been very dull not to have sooner thought of this mode of employing so valuable an agent as oxygen.

It has been long known to physiologists that in certain fishes the mucous lining of the alimentary canal performs a very important part of the work of the respiratory system. Some members of the gar family are killed as quickly by cutting off the supply of oxygen to the alimentary canal as by interrupting the gill respiration. Great numbers of illustrations might be given from the lower classes of the animal kingdom in which the entire process of respiration is carried on by the mucous lining of the alimentary canal. Why, then, should not man, whose alimentary canal is very much more extensive and better fitted for absorption than in lower animals, also be able to receive a very appreciable and effi-

cient amount of oxygen through this channel? In my experiments thus far I have found that patients take without inconvenience from one to two litres of the gas at a time, and this dose can be repeated three or four times in the twenty-four hours without any difficulty. I have never found any serious discomfort to be produced, although in large quantities it does not seem to be tolerated quite so readily as the carbon-dioxide and sulphuretted hydrogen mixture.

I am employing the oxygen enemata in a variety of cases, in one of which, a case of phthisis, the beneficial results arising from the gas have been surprising. When the treatment was begun the patient had for some time had an evening temperature varying from two to three degrees above normal. The morning temperature was from 99° to $99\frac{1}{2}^{\circ}$. Within forty-eight hours after the use of the oxygen was begun the temperature fell to normal, and did not rise above 99° at any time until about two weeks after the beginning of treatment, when the febrile symptoms reappeared as a result of an operation for the relief of a troublesome hemorrhoid, following which the patient by imprudence contracted a slight cold.

In the use of the oxygen enema I have employed a new form of apparatus, which I devised some time ago, and which I described in a paper read before the late meeting of the Medical Association in Chicago. The especial advantages of this apparatus are convenience in use, precision in dose, and an easily-regulated and perfectly uniform flow.

THE FOUR CEREBRAL HEAT-CENTRES.

BY ISAAC OTT, M.D., AND WILLIAM S. CARTER.*

THE discovery that fever† is mainly a disease of the nervous system, that albumoses, peptones, the leucomaine neurine,‡ produce fever through it, that the modern antipyretics reduce fever by an action on it, all of which can be shown by the curarization of animals, have stimulated us to study more minutely the heat-centres first discovered by one of us to be about the corpus striatum. The ascribing of fever, sleep, and the action of peripheral irritants to the modifications of

the circulation is an entirely erroneous view of the true state of affairs in these cases; the circulatory changes are merely associated phenomena.

Method.—Our experiments were performed upon rabbits, and punctures of the brain made through trephined openings in the skull and through the orbit. After the operation the wounds were cleansed with a sublimate solution, the parts united by sutures, and the animal permitted to run about the laboratory. The trephine used was usually one about three millimetres in diameter, occasionally a larger one of Pasteur's. The instrument with which we punctured was about three millimetres in width at its point and a millimetre in the shank. To hit the anterior ends of the thalami, or parts in front of them, we felt for a prominence just back of the orbit, and drew an imaginary line through its middle, making the puncture about a millimetre from the median line. After the observations were completed the animal was killed, and sections of the brain made to determine the seat of the puncture. The thermometers used were corrected at the Yale Observatory, and the bent rectal thermometer was always used in the same manner. The calorimetric observations were made with D'Arsonval's calorimeter, which was surrounded with feathers, felt, and saw-dust. The error is $.025^{\circ}$ F. for each degree the air is above the temperature of the calorimeter. We used the instrument so that it was about a degree below the temperature of the surrounding air. One of us has already determined that the cortex overlying the basal ganglia has when injured but little effect upon the temperature. Lesions of the cortex beneath the thalami cause a slight fugitive increase.

One of us, in July, 1885, determined that the thalamus increases the temperature by augmenting heat production.

Drs. Sachs§ and Aronsohn, in October, 1885, have shown that wounds of the tissues about the corpora striata and the nodus cursorius increase the urinary nitrogen, the amount of oxygen absorbed and carbonic acid exhaled, and the pulse and respiration. These facts do not prove that the increased temperature is due to increased production, for D'Arsonval¶ has shown that chemical processes do not give the exact measure of the production of heat, since the incubating egg

in its first stage absorbs considerable heat and also oxygen, whilst it exhales carbonic acid. It is necessary to study in addition arterial tension, and also make at the same time

FIG. 1.

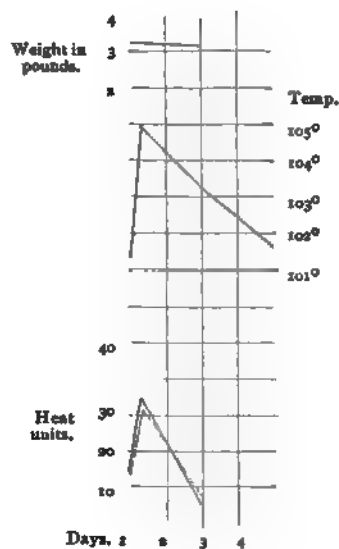

calorimetric observations, to be absolutely sure that the thermometric increase is due to augmented production of heat. This we

propose to do in this paper, so that at the same time we can give the height of the thermometer, the amount of heat production and heat dissipation, and the decrease of weight for each day of the fever.

1. *The Heat-Centre about the Corpus Striatum.*—It has already been noted by one of us,* when a transverse section of both corpora striata were made, that the temperature rose rapidly to $111\frac{1}{2}^{\circ}$ F. Lesions in front of and beneath the corpus striatum cause a rise of temperature. Thus we have discovered that a transverse section a millimetre in front of the anterior ends of the striate bodies is followed by a rapid rise of temperature, which lasts till the third day. In Fig. 1 the continuous line shows the quick rise and the slow fall of temperature. Fig. 2 shows that

FIG. 2.

heat production is immediately increased, as is also heat dissipation, but on the second day they both fell below normal. On the third day the temperature was about normal, being a little above it. This is the most anterior point in the brain which will cause any marked rise in temperature.

2. *The Caudate Nucleus* (Sachs and Aronsohn).—It was discovered by Drs. Sachs and Aronsohn that on the median side of the nodus cursorius a puncture causes a gradual increase of temperature, which reaches its height in twenty-four to seventy hours.

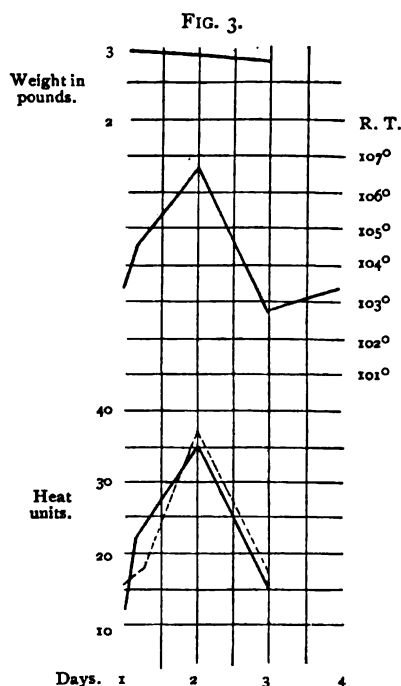

Girard† has also confirmed these observations. Baginsky‡ has extirpated the caudate

nucleus, and seen a rise of temperature. We have studied the effect of punctures in this region, and find, as they state, the rise of temperature does not reach its acme till the second day. In Fig. 1 the dotted line shows this gradual increment of temperature. This slow rise is preceded, by a fall, which is not great and lasts but a short time. As to the effect of puncture on heat production and heat dissipation our researches have yielded the following results. With a falling weight, the temperature, heat production, and heat dissipation were increased, and this increase was greater next day. On the third day they fell, the temperature below normal, heat production above normal, and heat dissipation to normal. These changes are illustrated by Fig. 3.

That increase of temperature is not always a sure index of increased heat production is shown in Fig. 4, where the temperature attains its height on the third day, but both heat production and heat dissipation are steadily falling. The question now arises, Can the increase of respiration, cardiac activity, and arterial tension be the cause of the elevation of temperature in wounds of the substrate and the striate centres themselves? By examining Fig. 5 it will be seen that in an animal bound down they all rise for a short time, as also does the temperature; but when the temperature is at its height they are all falling, except the respiration is suddenly increased by allowing the animal to be un-

bound. From these data we think it fair to state that without doubt punctures in the neighborhood of the corpus striatum and about the nodus cursorius cause a heightened temperature, due to increased production of heat. Exceptionally, whilst the temperature

is rising, both heat production and dissipation are steadily falling.

In all our experiments the weight steadily decreased, even when the animal ate with its usual gluttony.

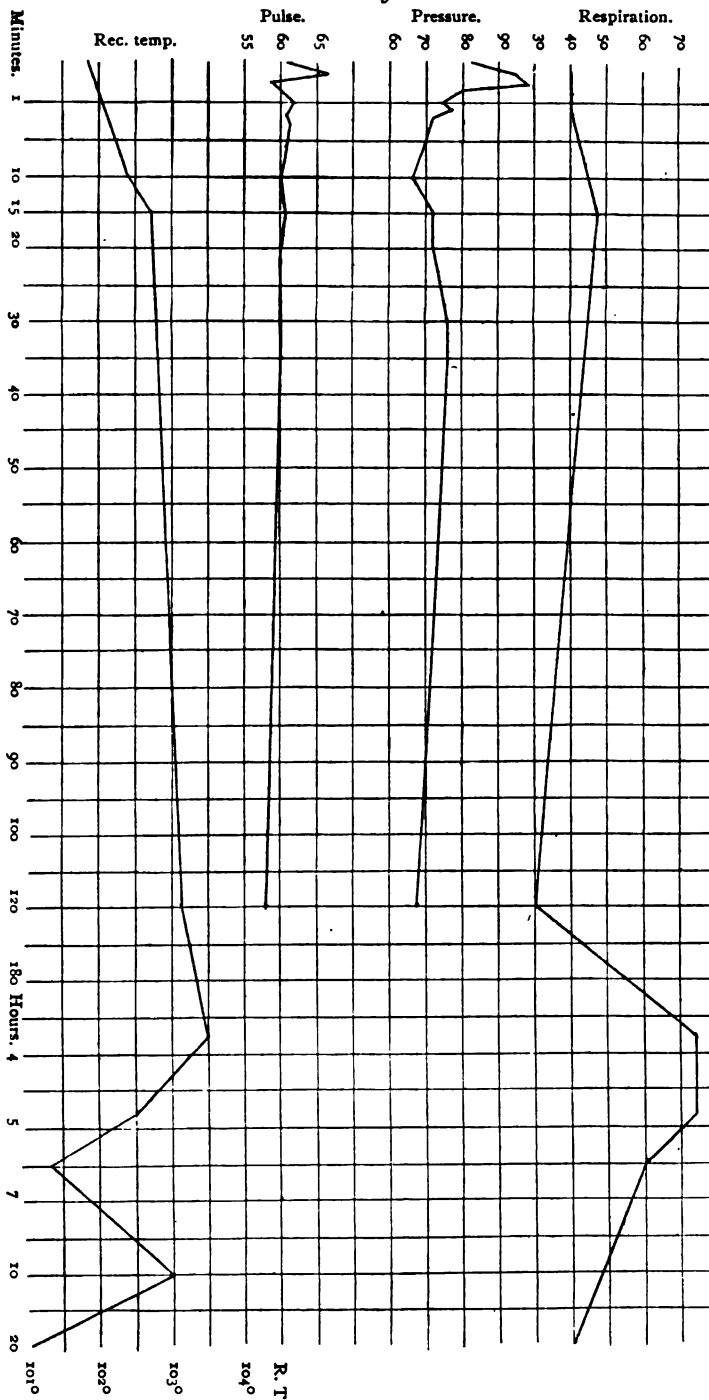

3. *The Anterior Inner End of the Thalamus Opticus.*—We have again subjected this point to thermometric and calorimetric tests. Transverse section of the optic thalamus caused a rise when it penetrated the anterior inner part, showing that these centres are not in the base of the thalamus.

The rise of temperature after lesions at this point is rapid, attaining 109° F., and falling in six to twelve hours below normal. The continuous line in Fig. 6 illustrates this point. With the calorimeter the heat production increases with the temperature, as also does heat dissipation. These data are well shown in Fig. 7. The query also arises here, Is this increase of temperature due to accelerated circulation, respiration, and augmented arterial tension? By an examination of Fig. 8, they are all found to have been falling at the time the temperature is rising. The subsequent sudden rise of the curve of respiration is due to the unbinding of the animal. These curves show that the increase of respiration, circulation, or arterial tension has no part in the increment of heat production after injuries at the anterior inner end of the thalamus.

4. *The Heat-Centre about Schiff's Crying-Centre.*—When a puncture is made in the tissues between the optic thalamus and the corpus striatum near the median line the rabbit

states that the cry occurs only in males, but we cannot confirm anything about this point, having made no careful observations. The rise of temperature here is rapid and slowly

FIG. 5.

often utters a peculiar cry, which is soon followed by increased temperature. Schiff *

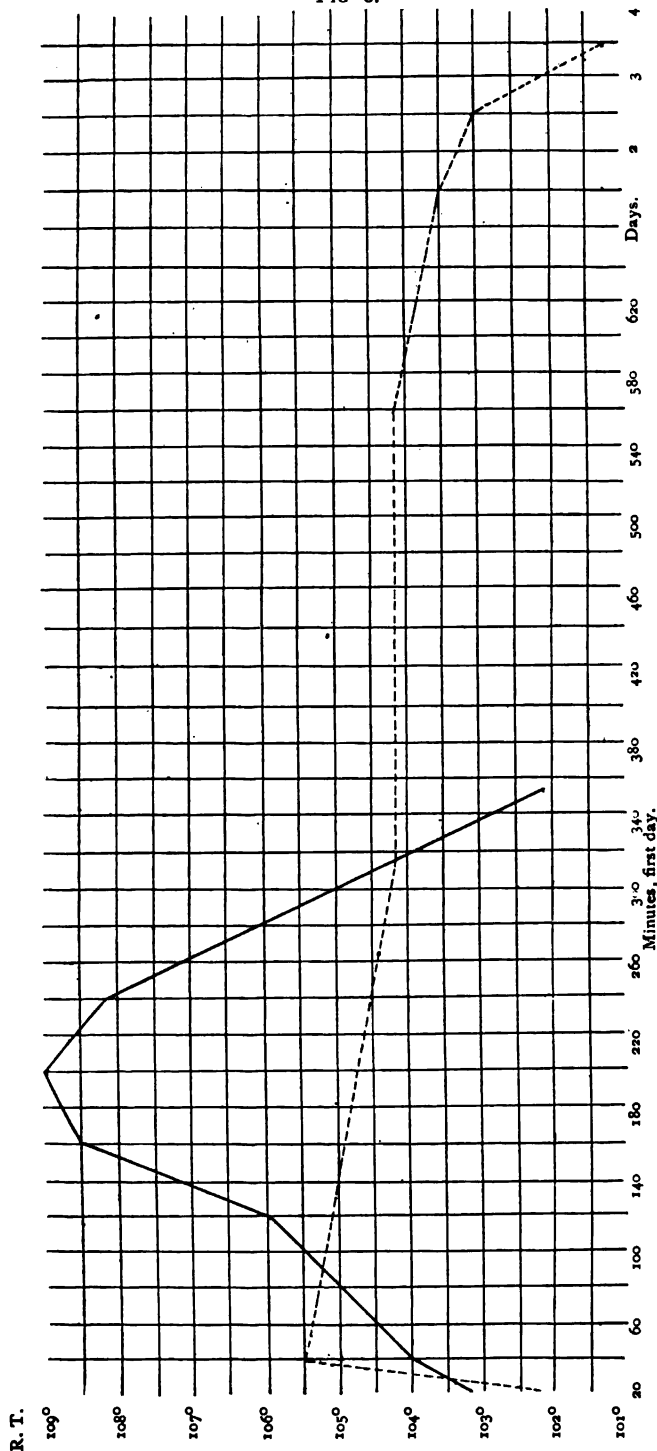

descends, not reaching normal till during the third or fourth day. The dotted line in Fig. 6 illustrates the course of the temperature. When the temperature rises heat production

* Lehrbuch der Physiologie des Menschen, 1859, p. 349.

and heat dissipation are increased, but on the following day they are below normal, although the temperature does not reach the normal level till the fourth day. A loss of weight

sion is proven by Fig. 10, where at the time the temperature rises greatly they are falling. The sudden rise afterwards in respiration is due to unbinding the animal. From these

FIG 6.

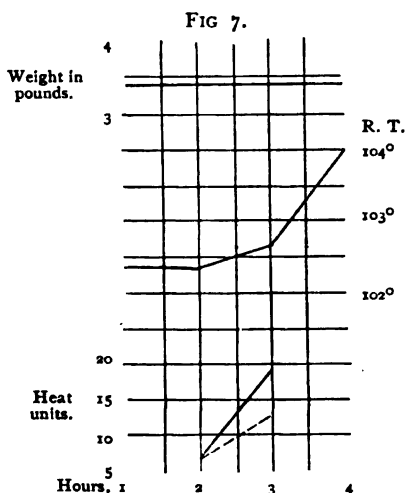

slowly took place during these observations. All these facts are shown in Fig. 9.

That this rise is not due to increase of cardiac action, respiration, and arterial ten-

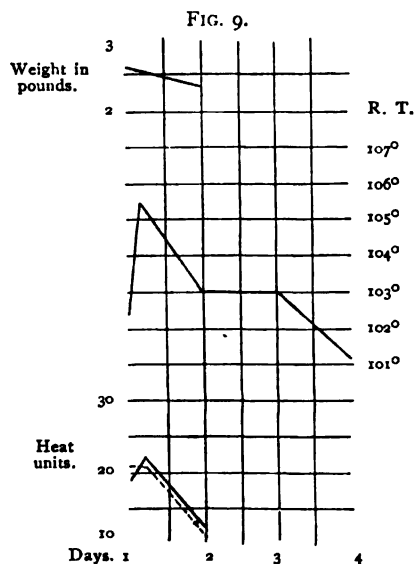

observations we conclude that the heat-centre about Schiff's crying-centre does not increase heat production through the blood, its movements, or its oxidation.

5. *The Value of the Four Heat-Centres compared with each other.*—We shall first consider the point with regard to the elevation of temperature. The anterior inner part of the

fourth day. Of course a division of the heat-centre on both sides of the brain will cause a greater rise than when one side of the brain is injured. The tissues beneath the corpora

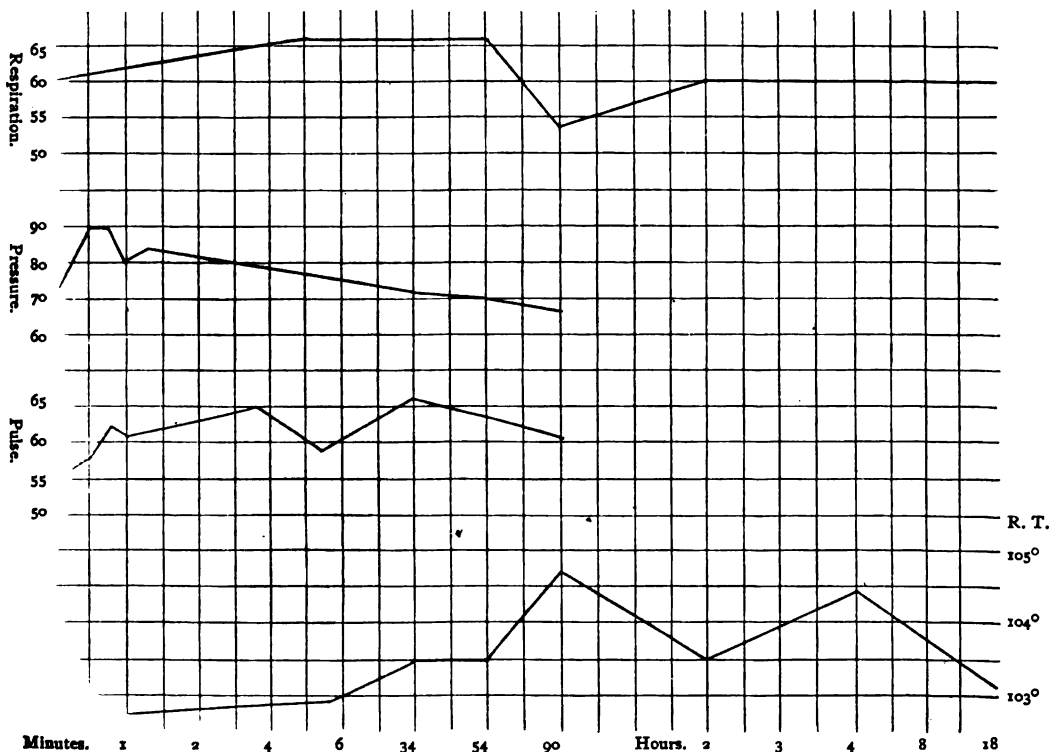

optic thalamus gives us a temperature frequently of 109° F., a rise of 6° F., whilst the highest rise to be found in any of the experiments of Sachs and Aronsohn about the

striata cause a rapid rise of temperature, which continues till the third or fourth day,

FIG. 8.

corpus striatum is 43.2° F., and this is not usual. As to duration of the elevation, the parts about the nodus cursorius and Schiff's crying-centre seem to continue up to the

but the rise is never equal to that caused by injuries of the thalamic centre. In Fig. 11 we have given the location of these centres in the brain: 1 is the heat-generating tissue be-

A NEW METHOD OF TREATING PHTHISIS
BY SUPER-ALIMENTATION.

DR. LANGOWAI, of the clinical staff of Professor Ostronmoff, in Moscow, has used with good results the following treatment, which he reports in the *Pharmaceutische Zeitschrift für Russland*, 1887, No. 24. Reviewing the mortality from phthisis, Langowai estimates that two-thirds of all deaths from chronic illness are from phthisis; he passes over with a brief mention the various germicides proposed to destroy the tubercle-bacillus, and describes at length the method of the French physician Debove, who, in treating a case of phthisis which was unable to retain food, had washed out the stomach, and so secured freedom from nausea and vomiting; he introduced through a stomach-tube extra diet into the patient's system—milk, soup, and eggs—with a favorable result: the cough and night-sweats grew less, and there was a gain in body weight of fourteen pounds in three months. Further investigations by Debove proved the increased assimilation of food by the increase in the urinary constituents excreted, which rose from a proportion of sixty to that of eighty. Later

in his treatment Debove added meat-powder to his other articles of diet, in quantities of from six drachms to twenty-five ounces daily. He was followed by a large number of other experimenters. For his investigations Langowai selected five cases of phthisis in the Moscow Clinic, in whom every means of diagnosis proved the existence of the disease in pronounced form. It was found that those cases in whom the parenchyma of the lung was not badly diseased sometimes recovered perfectly, while the worst cases were maintained for a long time. Langowai used in his treatment milk and meat-powder, the latter of which was prepared as follows: the best quality of meat was carefully freed from tendon and fat, and reduced to fine hash in a chopping-machine; it was then carefully dried in an oven at a temperature not exceeding 50° C. After drying the meat was powdered in a mortar and put through a fine, but non-metallic, sieve; the product was a fine powder, free from tendon, and having a faint odor of flesh. When the temperature was higher than 50° C. the meat was burned, and emitted an unpleasant odor. This meat-powder was kept in well-corked glass vessels, in a cool, dry place. By the method thus described neither the chemical nor histological properties of the meat were destroyed, the latter of which is especially important, as the microscope can reveal the addition of foreign substances in preparations offered for sale. The only change which the meat underwent was the loss of water, and this occurred in the proportion of three-fourths its body weight. To meet an objection which may possibly be raised by reason of the cost of the meat employed in making the powder, Langowai proposes the substitution of horseflesh for such as is generally employed. This meat is but little inferior to beef, as will be seen when we compare the two:

	Beef.	Horseflesh.
Salts, albumen, etc...	13.8 per cent.	12.5 per cent.
Phosphoric acid.....	1.69 "	1.66 "

Horseflesh is as well digested and gives as good results as beef. The above analysis is taken from Rubin. The meat-powder is given in sweetened water, with the addition of wine or peppermint-water. It may also be given in milk, soup, or spread upon bread with butter and cheese. Langowai gave his patients an amount of this powder equal to three pounds of meat. The merits of this treatment are sufficiently great to warrant apothecaries in preparing and keeping such meat-powders.

AMYLENE HYDRATE—A NEW HYPNOTIC.

AMYLENE HYDRATE is the most recent and promises to be one of the most important of the many late additions to the list of hypnotics. For its introduction we are indebted to Prof. J. von Mehring (*Therapeutische Monatshefte*, July, 1887). This substance, which belongs to the group of tertiary alcohols, was first discovered by Wurtz, and is prepared by treating trimethylethylene with sulphuric acid, amyl sulphuric acid being formed as an intermediate stage and breaking up on distillation with water, the tertiary alcohol being formed. Its more correct scientific name is dimethylethylcarbinol, and is represented by the formula $C_5H_{12}O = (CH_3)_2C(C_2H_5)OH$. Amylene hydrate is described as a clear, colorless liquid, with a penetrating odor, recalling camphor, oil of peppermint, and paraldehyde. It has a specific gravity of 0.81; when pure it boils at 102.5° Centigrade. Upon cooling it to 12.5° it solidifies in acicular crystals that melt at 12° Centigrade. It dissolves in 8 parts of water, and is miscible with alcohol in all proportions. Amylene hydrate appears to be specially liable to contamination

with amylic alcohol, which may be detected if present by the formation of valerianic acid upon oxidation with potassium bichromate and sulphuric acid.

In 1885 Von Mehring and Thierfelder (*Zeit. f. Phys. Chemie*, Bd. 1. s. 9) showed that when this substance was given to rabbits it was excreted as a compound of glycuronic acid, but in man and dogs was, to the greater part, as is ordinary alcohol, subjected to combustion. These experiments indicated that this substance was, in all probability, possessed of marked hypnotic properties, and for the last two years Von Mehring has been extending his experiments in this direction both on animals and on man, and he now announces that as a hypnotic amylene hydrate stands midway between chloral hydrate and paraldehyde, one gramme of chloral hydrate being estimated as equal to two drachms of amylene hydrate or three drachms of paraldehyde. His experiments were first made on frogs, rabbits, and dogs, and he found that hypodermic injections of 0.06 to 0.1 gramme in a frog, or 2 to 3 grammes introduced into the stomach in rabbits or 8 grammes in dogs, produced within ten to thirty minutes a deep sleep, which lasted from six to eighteen hours, animals appearing perfectly normal when the effects of the hypnotic pass off. In these doses, which were found amply sufficient to produce profound narcosis, scarcely the slightest impression was made upon the respiratory functions, respiration in the dog being reduced from twenty only to sixteen respiratory movements in the minute, a difference which is no more marked than occurs in normal sleep. The circulation likewise is scarcely affected by this drug, differences in the pulse-rate and blood-pressure after the administration of amylene hydrate being scarcely perceptible, a marked contrast to the serious effects often produced by chloral. The physiological action of this substance appears to be exerted principally upon the cerebrum. In larger doses it extends to the medulla oblongata, reflex action disappears, respiration slackens, and finally the heart stops. In doses suitable for the production of narcosis neither the respiration nor the heart's action are perceptibly affected, and Von Mehring states that he has even administered this drug to patients with extensive heart-defects with the most satisfactory results.

In all he has given amylene hydrate to sixty different individuals in three hundred and fifty different doses, each dose varying from 3 to 5 grammes (50–90 gtt.). The affections in

which he employed this substance were of the most varied character,—sleeplessness from nervousness, in delirium tremens, phthisis, and in convalescence from various febrile diseases. Only in four cases out of all these did it prove inefficacious. Twice it was employed in whooping-cough with a favorable result, but, like chloral, it proved unreliable in producing sleep when the wakefulness was due to pain. It is said to possess a less disagreeable taste than paraldehyde, and the exhalations after taking it are not so disagreeable. From its freedom from danger and more pleasant taste it is evidently to be preferred to either chloral or paraldehyde, even though it be weaker, as a hypnotic, than chloral. It may be administered internally or in enemata. Von Mehrling gives the following formula :

Amylene hydrate, 7 grammes ;

Aq. dest., 60 grammes ;

Extr. liq., 10 grammes. M.

S.—The half to be taken at night for sleeplessness.

Amylene hydrate, 5 grammes ;

Aq. dest., 50 grammes ;

Mucilag. gummi arab., 20 grammes. M.

S.—For use as an enema.

In sleeplessness from pain amylene hydrate may with advantage be combined with hydrochlorate of morphine. No unpleasant after-effect of any kind, according to Von Mehrling, follows the employment of this substance ; no nausea, vomiting, headache, or disturbance of digestion.

It must not be forgotten that hypnone, methylal, cannabinone, paraldehyde, hyoscine, and urethan, when first brought before the medical profession, were all supported in the strongest possible manner, and nearly every report of their employment was of the most favorable character. It was only as our experience became more extensive with these different substances that we found the use of one and all of them was in many cases attended by serious drawbacks. Perhaps amylene hydrate may prove no exception to this rule, although it must be confessed that its prospects as yet appear very promising.

A NEW VERMIFUGE.

DR. M. MARTINET writes to *Les Nouveaux Remèdes* for July, 1887, attributing vermifugal properties to the leaves of the *Sida Floribunda*. It appears that for the discovery of this substance M. Martinet was indebted to the instinct of his dog, which, after having

been sick for a number of days, himself sought out and devoured some leaves of this plant, and a few hours later was relieved at the same time of his sickness and a large number of intestinal worms. The plant is said to be very common in the neighborhood of Lima, and is a Malvaceæ of the genus *Sida*, and is designated under the name of *Sida Floribunda*. The mucilage, which is so abundant in the different species of Malvaceæ, is likewise present in this plant, but no substance can be discovered on chemical analysis to which its anthelmintic properties could be attributed. Microscopic examination, however, shows that all the leaves of this plant are covered with extremely minute resisting spines, and the vermifugal properties are, if present at all, without doubt to be attributed to the mechanical action of the plant. Their smallness enables them to escape destruction in mastication, and their structure, being composed almost entirely of cellulose, protects them from digestion, and, reaching the small intestine, they act as a mechanical vermifuge, in the same manner as kamala, which likewise should be included among the group of mechanical vermifuges.

ONE OF PASTEUR'S CRITICS.

ONE of the most amusing of the many wild criticisms to which Pasteur's anti-rabic investigations have been subjected appears in a recent number of the *Contemporary Review*, over the signature of Frances Power Cobbe. Miss Cobbe, we believe, is one of the shining lights of the English Society for the Suppression of Vivisection, and she finds her explanation of both the appointment and the favorable character of the report of the English Hydrophobia Commission in the determination of the English physiologists to obtain at any price any argument for doing away with the restrictions on English vivisection.

Miss Cobbe recognizes that if Pasteur's conclusions were true the best possible argument for abolishing restrictions on vivisection would be afforded, but she directly claims that the only reason why Pasteur's experiments have attracted the attention of all scientists is to be found in their cruelty.

"If Pasteur's vaunted remedy had been obtained without any cruel experiments ; if he had professed to cure hydrophobia by a method brought to light by clinical or microscopical observation, would he have been welcomed by the men of science of England as an illustrious '*savant*' ? Tell it to the marines."

Reports on Therapeutic Progress.

PILOCARPINE IN PUERPERAL ECLAMPSIA.

At a recent meeting of the South Australian Branch of the British Medical Association Mr. J. H. S. FINNISS, M.B., C.M. Edin., related a case of puerperal eclampsia in a woman, aged 24, treated by hypodermic injections of nitrate of pilocarpine (*British Medical Journal*, July 16, 1887). The first seizure occurred twenty-one hours after delivery; the fit was preceded by severe headache. Resort was at first had to chloral and bromide of potassium, combined with the administration of ether during the epileptiform fits, but without much benefit. The first dose of nitrate of pilocarpine ($\frac{1}{4}$ of a grain) was administered hypodermically at 7 A.M., thirty-seven hours after delivery. Within a minute or two profuse perspiration came on, and saliva poured out of her mouth; the pupils contracted a little. She had five more convulsions, with stertorous breathing in the intervals, up to 8 A.M., when the dose was repeated. She had had three more convulsions up to nine o'clock, but these were milder and shorter. During each fit ether was administered to assist in lessening arterial tension. She had no other fit until 2 P.M., she had another at 2.30 P.M., and a very severe one soon after 3 P.M. Nitrate of pilocarpine, $\frac{1}{4}$ of a grain, was injected; it produced the same physiological action as in the morning. At 8 P.M. she had slept for three hours; the temperature was 104.2° ; she was still unconscious; she passed urine and her motions in bed, but had had no more convulsions since the third injection. At seven o'clock the next morning her temperature was 103° ; she had had no return of the convulsions, and had slept at intervals through the night, but was still unconscious. At 8 P.M. of the same day the temperature was 98.2° ; she had had a good calm sleep for three hours in the afternoon. She subsequently progressed favorably. There was a trace of albumen in the urine when it was examined on the second day.

WARNINGS ABOUT THE USE OF ACETANILIDE.

Two articles have recently appeared in the Hungarian medical journal *Gyógyászat*, in which the profession is warned that acetanilide, or antifebrin as it is called, though

it is not without value, is an uncertain, and indeed a dangerous, antipyretic. Dr. Géza Dulácska finds, after giving the drug a prolonged trial in the hospital, that small doses may bring down fever, but that in some cases even 3-grain doses produce violent sweats, prostration, and hemorrhage or cyanosis. It does not appear to him to exert any favorable action on the course of the disease itself, being thus inferior to salicin, resorcin, and ichthyol. If given at all in fever, its action requires to be very carefully watched. In certain neuroses, however, Dr. Dulácska has found it very useful, and as the doses required were smaller, he is disposed to recommend its employment in such cases as it appears to be free from danger. In a case of severe trigeminal neuralgia, in which quinine, gelseminum, and morphine had produced but little improvement, 3 grains of acetanilide were given night and morning without effect; $7\frac{1}{2}$ grains were then ordered, divided into ten powders, one to be taken every two hours. This produced a great improvement, and after ten days of this treatment the cure was complete. No unpleasant effects beyond some nocturnal perspiration showed themselves. Two other cases, where severe pain was associated with meningo-myelitis and syphilitic tabes respectively, which had been treated in various ways unsuccessfully, were greatly benefited by acetanilide, no unpleasant effects being produced. Dr. Biro gave acetanilide in eighteen cases of various kinds, including typhoid, croupous pneumonia, pleurisy, polyarthritis, tuberculosis, and phthisis, in doses varying from $1\frac{1}{2}$ grains to 45 grains per diem, and was much struck with the uncertainty of its action, an effect being sometimes produced by a grain and a half, while at others ten or eleven grains had no effect at all. Most of the patients complained of chilliness, while cyanosis and irregularity of pulse occurred in several cases. In one case, where seven grains and a half had been taken, there was a severe rigor followed by cyanosis, sweating, and an irregular, thready pulse, the symptoms being so alarming that recourse was had to brandy and hypodermic injections of ether. In another case, in which acetanilide had been given for eleven days, similar symptoms presented themselves, together with clonic spasm of the lower extremities, reminding one of the symptoms in aniline poisoning. Altogether, Dr. Biro thinks that the evil effects of acetanilide are so great that it cannot be recommended for general adoption.—*The Lancet*, July 9, 1887.

*THE TREATMENT OF SEVERE CASES
OF BURNING BY THE HEBRA
WATER-BED.*

The method of treating burns by prolonged immersion in baths does not seem to be as thoroughly known as it undoubtedly deserves to be. The bed recommended by Hebra is simply a special form of bath, and is admirably adapted for treating not only cases of burns, but all diseases associated with loss of epidermis, such as extensive sloughing ulcers, erysipelas, and other diseases associated with severe pain. The entire absence of pain and apprehension on the part of the patient, associated with the removal of old dressings and application of fresh ones, is a marked and favorable element in treatment by the bath. The wounded surfaces are continually out of contact with the air, and, as they are not covered with any form of dressing, the discharges escape at once into the water, and the wounds are kept clean.

There is scarcely any limit to the time a patient may remain in the bath. Immersions have been prolonged as much as three hundred and eighty-five days and nights. In the *Edinburgh Medical Journal* for July, 1887, DR. W. J. LAWRIE gives the following description of the employment of Hebra's water-bed :

It consists of a zinc vessel, constructed in the framework of a bed. In the vessel an oblong iron frame is suspended by chains. The frame is so constructed that the portion where the patient's head is to lie may, by a hinge motion, be raised to an angle with the other part. The whole frame can be raised or lowered by means of toothed wheels. On the frame a thin mattress is laid ; the patient rests on the mattress. When the zinc vessel has been filled with water, the bed, carrying the patient, is gradually sunk beneath the surface, taking care, of course, to keep the head out of water.

At first the patient feels the water too hot, upon which it must be cooled. Feelings of rigor now set in, and additional warm water must be added. After this he feels most comfortable ; the pains have almost entirely disappeared.

The water-bed does not offer a remedy against the severe constitutional effects of all burns, nor against their fatal ending in all cases. Patients die of extensive burns under this treatment as under any other, but they die at least free from pain.

On the other hand, the continual bath is an effectual therapeutic agent, and a real benefit for patients and attendants during the long

period of suppuration. By the ordinary methods such patients cannot be kept in a state of perfect cleanliness, because the dressing of extensive burns requires much time. Lifting and turning, as well as separation of the adhering bandages, are most painful. Here fresh bleeding is induced, there retention and degeneration of the secretions occur, and fever is constantly maintained. There is continual dread of septicæmia, and constant nervous apprehension on the part of the patient at each dressing of the wounds. All of these disadvantages cease on the use of the water-bed. The patient lies and moves as he wishes, sleeps, eats, and employs himself according to his tastes. The wounds are always covered, always clean, and granulate normally, indeed often so luxuriantly that they must be repressed.

According to those indications, therefore, Hebra's water-bed is, from the beginning, the best agent against pain, and during the period of suppuration is the best therapeutic agent. Removal of scabs takes place earlier. Retention of pus is avoided. Danger of septicæmia and erysipelas is reduced to a minimum, fever ceases, sleep and appetite return, by means of which the organism is enabled to withstand the effects of severe suppuration. In a word, granulation and healing, with the absence of all subjective and objective accompaniments, are furthered to an extraordinary degree by the water-bed.

*TREATMENT OF ANAL FISSURE AND
HÆMORRHOIDS BY GRADUAL
DILATATION.*

Anal fissure, or irritable ulcer, according to statistics, ranks third in frequency among the diseases of the rectum, is found in the infant as well as in the octogenarian, and is due principally to the passage of hardened fæces through the sphincters. Although insignificant in character, it causes fully as much exquisite agony as any ill that human flesh is heir to. Very many simple fissures get well promptly, but where, by frequent mechanical irritation, they come to stay, it is then that beneficial treatment is desirable. Many cases will, however, refuse a radical operation, and for this reason DR. H. O. WALKER (*New York Medical Journal*, July 30, 1887) recommends the treatment of such cases by gradual dilatation. He was led to employ this process in a case which refused operation, and in which various forms of treatment by suppositories failed to produce relief. Dr. Walker

in this case introduced a bi-valved rectal speculum, slightly separating the blades, and allowing them to remain *in situ* for about two minutes. This procedure was continued daily, gradually increasing the dilatation at each sitting until the blades were separated to their fullest extent,—about two inches in diameter. This treatment was continued until there was an entire subsidence of all previous symptoms, with a full healing of the fissure and hæmorrhoidal tumors and disappearance of constipation; entire treatment lasting about five weeks. Dr. Walker likewise reports in detail four other cases taken from a record of upwards of fifty, which he has treated by this method, and which he considers are fair representatives of the character and results of the whole. In all of these cure was produced. In conclusion, he recommends the treatment of anal fissure and hæmorrhoids by gradual dilatation on the following grounds:—

1. It is almost painless, at least after the first two or three distentions.
2. It does not tear the parts, nor does it produce paresis, as occasionally occurs after forcible dilatation.
3. Neither does it leave cicatrices that are apt to produce stricture, as in the method of hypodermic injection or ligature of hæmorrhoids.

ANILINE CAMPHORATE.

Referring to the fact that the recent discovery of antipyretic properties in acetanilide ("antifebrin") has opened up a possible future in therapeutics for another group of compounds, aniline derivatives and salts, HERR VULPIUS points out that a compound of aniline and camphoric acid had previously been credited by Tomaselli with antispasmodic properties (*Pharm. Centralh.*, June 9, p. 283). This salt does not usually figure in trade-lists, but Hager, in his *Handbuch der Pharmaceutischen Praxis* (vol. i. p. 364), states that it can be prepared by dissolving fifty parts of camphoric acid ($C_{10}H_{16}O_4$) in one hundred and fifty parts of absolute alcohol, and adding to the solution fifty-six parts of aniline, or sufficient to produce a neutral liquid, which is then left to evaporate spontaneously in a dark place. The product so obtained is described as occurring in small white or reddish odorless prisms, having a pungent acrid taste, and easily soluble in water, alcohol, and ether. This formula is objected to by Herr Vulpius on the ground that excess of aniline is ordered, and that it

is difficult to ascertain the exact point of neutralization with ordinary indicators, paper stained with the violet coloring-matter of dahlia petals, which is colored green by aniline, being the most convenient. Moreover, he considers the use of alcohol as unnecessary, and liable to lead to discoloration during evaporation, even in the dark. He prefers to heat together in a closed vessel, at the temperature of a boiling water-bath, one hundred parts of finely powdered camphoric acid and ninety-three parts of aniline. The crystallization of the aniline camphorate is said to commence in a few minutes but to take some time to complete, though its progress is accelerated by contact with a wide surface of the containing vessel. Aniline camphorate— $(CHN)CHO$ —thus prepared, is said to dissolve in alcohol and ether, but not freely in water, of which it requires about thirty parts, and in its solubilities generally it approximates to aniline rather than to camphoric acid. Chloroform and carbon bisulphide appear to break up the compound, taking up the aniline and leaving a residue of camphoric acid; heated fat oils and oil of turpentine behave more or less similarly. Apart from alcoholic and ethereal solutions which are not adapted for hypodermic use, the best solvent for aniline camphorate is glycerin, which takes up one-tenth of its weight, and can then be diluted with an equal weight of water. The maximum single dose of aniline camphorate given by Tomaselli as an antispasmodic was .02 gramme, and the maximum quantity administered in one day .08 gramme, which was usually given dissolved in four volumes of ether or ether-alcohol, and inclosed in a gelatin-capsule.—*Pharmaceutical Journal and Transactions*, June 25, 1887.

THE TREATMENT OF NEURALGIA BY MEANS OF INTENSE COLD.

At a recent meeting of the American Neurological Association, Dr. JACOBY read a paper on this subject, in which he set forth the advantages attending the use of chloride of methyl and liquid carbonic acid (*New York Medical Journal*, July 30, 1887). His general impression was that we had in chloride of methyl a reliable analgesic which did not affect the general condition of the patient, and that it was invaluable in the treatment of neuralgia for the immediate relief of severe pain. It was used in the form of spray under high pressure. The objections to be overcome were the expense of the apparatus and

the difficulties of getting the drug. From his experience in the use of condensed carbonic acid, his conclusions were that, in the absence of chloride of methyl, it was able to take the place of that remedy in the treatment of sciatica; that the pain was relieved very promptly by it, but that its curative effect was not so great as that attributed to the chloride of methyl by other observers.

Dr. Edes and Dr. Dana had used rhigolene with benefit in the treatment of neuralgia, and so had Dr. Jacoby, but he had found it objectionable because of the less intense degree of cold produced, and also because it could not be applied to a sufficiently large surface.

TREATMENT OF DROPSY BY PERMANENT BATHS.

In the course of a paper (*Berl. Klin. Woch.*, 1887, No. 29) upon the use of permanent baths (at a temperature of about 95° F.), L. RIESS, after giving instances of their value in cases of spinal disease and injury, adduces some rather remarkable facts of their efficacy in the treatment of dropsy, whether cardiac or renal. These cases are often complicated with bed-sores, erysipelas, and gangrene, for which such treatment would be suitable, but he says that he long withheld it because of the idea that cardiac or pulmonary disease would be a contraindication to its employment. However, in 1879, in a case of extreme cardiac dropsy (mitral and aortic disease) with considerable erysipelas and cutaneous gangrene of the legs, he determined to try the effect of the permanent bath as a last resort, not without some misgiving lest the immersion should increase the dyspnoea and dropsy. The result proved quite the reverse, for a rapid improvement took place, and when, after having been in the bath a fortnight, the patient returned to bed, the dropsy and other severe symptoms had disappeared. Since then Riess has adopted the procedure in a large number of dropsical cases, and invariably with benefit, the dropsy in most cases (whether renal or cardiac) diminishing within the first forty-eight hours in a striking degree. The quantity of urine is not increased *pari passu*, so that it is suggested that the effect of the permanent bath is to increase the functional activity of the skin, which is contrary to the prevalent notion. The good results obtained in cases of chronic rheumatism so treated are also mentioned, and it is held that the application of the method is practically very sim-

ple, it being necessary of course to allow the patient to lie comfortably suspended in a hammock, and to place a thick woollen covering over the bath to retain heat as much as possible. At first it is well to allow the patient to leave the bath at night, but, as he gets more used to it, he may spend days and nights in it with much comfort both to himself and his attendants.—*The Lancet*, July 23, 1887.

NAPHTHOL IN THE TREATMENT OF ENURESIS.

DR. S. J. WRIGHT, of Tallmadge, O., writes to the *Medical Record*, July 30, 1887, as follows: "I had a case of enuresis, without cystitis or calculus or any pain, occurring in a neurotic lady 34 years old. The condition had existed since childhood. No relief had been found in local or general treatment. She had been obliged to rise many times every night for years. The quantity of urine passed each time was small, the total amount for the twenty-four hours being about three pints. A nervous cough had lasted a year in spite of treatment, and, fearing bacterial infection, I gave her a No. 2 capsule filled with naphthol, also using the drug in the form of a spray. The enuresis rapidly subsided during this treatment, although no change was visible in the appearance of the urine. A temporary cessation of the naphthol for a few days was promptly followed by a return of the enuresis, which again left on resuming the drug. She is now free from enuresis, and can sleep better than ever before. Her throat gives her no pain, her cough is nearly gone, and she can omit naphthol without a return of her enuresis."

COMMON ERRORS IN THE TREATMENT OF SKIN-DISEASES.

At a recent meeting of the Medico-Chirurgical Society of Montreal, DR. FOX read a paper on the "Common Errors in the Treatment of Skin-Diseases" (*The Canada Medical Record*, June, 1887). He said that the great error made by practitioners in treating skin-diseases was failure to treat the patient; the disease is treated, not the patient. It is most important that the patient have fresh air, wholesome food; in short, everything that tends to improve the general health. Special treatment of the disease is of no avail without improving the condition of the patient. He regarded attention to the diet as most important, and said there should be a radical

change both in the quantity and quality of the food; a strict course of diet should be given the patient; the majority of patients improve on starvation diet. He advised his patients to increase the quantity of fluids taken and decrease the solids; to eat less and exercise more. A change of diet almost invariably proves of value, the more radical the better; he gets the best therapeutical effects from a vegetable diet in the treatment of inflammatory skin-affections. A meat diet congests the skin; a vegetable diet relieves the congestion. He is in the habit of restricting the meat in winter and forbidding it in summer. In giving directions to a patient it is better to tell them what to eat than what to avoid. Water should be taken sparingly at meals, but in quantity between meals. In speaking of local applications, he said that very few are needed. If the disease be acute, soothing applications should be given; if chronic, stimulating ones. Infantile eczema is, as a rule, too much stimulated, and chronic eczema with infiltration too little stimulated. In treating psoriasis, chrysophanic acid is the best remedy, but even this remedy should not be used in every case, as it does positive injury where there are congestion and inflammation, but later, when the eruption becomes dry, it does good. In acne a tonic treatment is best. In speaking of local applications, the reader of the paper stated that when the substance is needed to be absorbed by the skin, then the animal fats should be used; when mere protection is wanted, then vegetable fats do very well. Vaseline has but little power of penetrating the skin. He then went on to speak of arsenic, which, he said, is used too much by the general practitioner in the treatment of skin-diseases, and which, as regards skin-diseases, would not be missed if abolished from the Pharmacopœia; he now rarely uses it. It is at best a much overrated remedy, and its indiscriminate use in skin-diseases is fraught with evil.

A NOVEL TREATMENT OF PLACENTA PRÆVIA.

DR. JOHN WINSLOW, of Ithaca, N. Y., writes to the *Medical Record* for July 30, 1887, as follows: "The interest lately shown by your correspondents in the subject of placenta prævia leads me to report a case whose treatment differed from any that I have seen described. Summoned in haste one night to a stout German primipara, I was at her bedside in less than five minutes after the mes-

senger had left it. The blood had already saturated the bed, made a pool under it, and flowed across the room. It was still pouring from the vagina, when, introducing the whole hand, I found the os about the size of a half-dollar, with the presenting placenta so firmly adherent all around that it could nowhere be detached, and too thick and firm to be penetrated by the finger. So, to check the hemorrhage, I closely applied the palm over the os (with the fingers in the posterior cul-de-sac, as the patient lay supine), while the external hand over the foetal breech strongly held the head against the placenta, the lowest part of which was thus firmly compressed. Hemorrhage was impossible, and not another ounce of blood was lost until, after four fatiguing hours of this steady pressure, the os had so far dilated as to allow one edge of the placenta to slip out, forced down by the head, which now of itself compressed the attached portion against the pelvic wall. Delivery was spontaneous and speedy; and the large, thick after-birth showed near its centre a circle some four inches in diameter much thinned and completely blanched. Both mother and child did well."

A NEW TREATMENT FOR OBSTINATELY RECURRING ECZEMA.

When the diathetic or other defect of health upon which most cases of eczema depend is duly met by general and medicinal measures, and the local applications are adapted to the stage and degree of inflammation, while the denuded surface is protected from the irritating influences of air and water, the vast majority of cases get well; but, in a certain number, just when we think that we have conducted the patient safely through the attack, a fresh outbreak occurs and we have to begin again, and this over and over again until the resources of the medical men and the patience of the sufferer are wellnigh exhausted.

In the *British Medical Journal* for July 9, 1887, DR. RADCLIFFE CROCKER proposes a means of treating these disheartening cases, which he believes will bring relief in the majority of instances. He was first induced to try this treatment in the case of a man, aged 56, who had had eczema on the hands and face, and had been incapacitated for work for three years. Various kinds of treatment were tried, both internal and external; but, although temporary improvement was obtained so that the discharges and hyperæmia diminished and he seemed to be getting well,

in a few days the eruption came out again as badly as ever, chiefly on the face and arms. Dr. Crocker came to the conclusion that it must be due to a vaso-motor neurosis, and that if he could get at the vaso-motor centre he might do some good.

Without in any way altering the treatment previously employed, he painted liquor epispasticus on the nape of the neck.

Owing to the thick scales the blister did not take, and it was repeated after cleaning the surface, and a good blister formed; a fresh acute attack was just threatening, but it did not come on, and the patient felt better. Three days later, the part having healed, the blister was repeated, and there was evident improvement after it; the scales were less, and the irritation was much relieved. The patient continued to improve, but, the rash threatening again, another blister was produced. This, however, did not stop the rash, which came out freely, but the itching was much less than usual, and the eruption lasted but a short time, and from that time he continued to improve and went out almost well, and was able to go to work for five months, but, having to keep his hands much in water, it then returned.

Encouraged by this result in a very unpromising case, he has extended this line of treatment, but using milder counter-irritants, such as mustard-plasters or mustard-leaves, instead of blisters, which are unnecessarily severe. Dr. Crocker reports several cases in which counter-irritation has been employed with the same results. The position of the counter-irritants should vary according to the region affected. Thus, for the face alone, it is placed behind the ears; for face and fore-arms, on the nape; about the genitals or legs, over the lumbar enlargement; and, if one leg only is affected, on the hip over the large sciatic nerve.

The result has been more or less beneficial in the great majority of cases. It has seldom failed to relieve the itching, and generally procured sleep, at least on the night of application, and often the alleviation has lasted for several nights. In many cases the redness and swelling have also subsided sometimes entirely, sometimes in great measure, and generally enough to make it more amenable to local treatment than it was before.

One advantage of this method is that it does not interfere in any way with other treatment, whether internal or external, and that it is safe; but, inasmuch as there is a natural shrinking from irritants on the part of

an eczema patient, it may be more prudent in some cases to begin with dry heat, such as a hot tile wrapped in flannel, and, if sufficient relief is not obtained, to go on to stronger applications.

SUBIODIDE OF BISMUTH AS A SUBSTITUTE FOR IODOFORM.

It is generally conceded that iodoform stands in the front rank of antiseptics and as a surgical dressing for various diseased conditions. Its use is nevertheless attended by a number of serious drawbacks.

An article which Dr. CHASSAIGNAC (*New Orleans Medical and Surgical Journal*, July, 1887) believes to be a good substitute for iodoform is the subiodide of bismuth, which was used some ten years ago by Dr. A. S. Reynolds, who found it very efficacious, but was not generally adopted at the time on account of its high cost.

Subiodide of bismuth is of a bright brick-red color, impalpable when well powdered, almost odorless and tasteless, insoluble in water, alcohol, ether, or chloroform. It does not stain or impart its color to linen, and is easily washed out. It can be made by different processes, but we will only quote from the *American Journal of Pharmacy* one devised by Jos. W. England, Ph.G., and recommended by him, in an article on the subject, as "practicable in general employment."

R Bismuth. subnit., ℥iiss, gr. xxiv;
Nitric acid, ℥iiss;
Hot water, ℥xii;
Potassium iodide, ℥xi, gr. iii;
Hot water, ℥xxviii.

Dissolve the bismuth salt in the acid in a porcelain capsule with the aid of heat, and add twelve fluidounces of boiling water in small portions at a time, stirring after each addition; then pour the bismuth solution in the hot water, in which has been dissolved the iodide, agitating it well after each addition. Continue agitating until decomposition is complete. Filter at once. Wash the precipitate with warm water. Dry and powder.

When subiodide of bismuth is dusted on a raw surface it produces over the latter a thin silvery film, somewhat analogous to that caused by lunar caustic when lightly applied, but much more faint. However, it imparts no stinging sensation, as this fact might suggest, but seems to have an anæsthetic effect similar to that of iodoform. It has a marked healing effect upon chancres, as well as chancreoids. Dusted over wounds, whether accidental or made by the surgeon's knife, it acts as an antiseptic, diminishes the secretion of pus, and seems materially to hasten cicatriza-

tion. It is a good deodorant, for Dr. Chas-saignac has applied it to chronic and foul ulcers of the leg, which, with ordinary application, required dressing daily or every other day, and with this could remain a week almost without being touched, and then be found without bad odor, having suppurated very little and granulated magnificently.

Its present price is now much less than iodoform, the latter selling at about five dollars a pound, while the subiodide of bismuth may be made so as to cost from three to three and a half dollars a pound.

A SIMPLE METHOD FOR ASSISTING DEGLUTITION IN ULCERATION OF THE EPIGLOTTIS.

One of the most distressing symptoms accompanying laryngeal phthisis with ulceration of the epiglottis is the difficulty patients experience in swallowing. Especially is this the case in advanced conditions where the epiglottis is more or less completely destroyed. In such circumstances the swallowing of even a teaspoonful of water, or liquid of any kind, is all but impossible, from the violent cough that is excited in consequence of the passage of some of the fluid into the larynx and trachea. Such patients are generally tormented with a thirst which they cannot satisfy, and the painful efforts they make to get down a few drops of liquid, and the terrible spasms of coughing and pain thereby produced, are truly pitiable to observe.

In the *Lancet* for July 2, 1887, Dr. R. NORRIS WOLFENDEN refers to a method of drinking large quantities of fluid with ease, even when the epiglottis has more than half disappeared from ulceration. The plan was suggested to him by a patient of his, who informed him that thinking of how boys are in the habit of drinking water from a running brook, by lying down upon the bank and putting the mouth to the water, determined him to adopt a similar position himself, and found by making use of a piece of india-rubber tubing that while lying stomach downwards, and with the feet higher than the rest of the body, and putting the piece of rubber tubing in the water, he was able to drink a large tumblerful without stopping and with the greatest ease and comfort, although in the ordinary position a teaspoonful of fluid was as much as he could manage to get down, and this was accomplished only at the cost of much pain and terrible paroxysms of coughing.

The plan is simple enough, and Dr. Wolfenden recommends it as an excellent method for alleviating one of the most distressing symptoms in patients suffering from such laryngeal conditions.

THE TREATMENT OF OBSTINATE CASES OF FLEXIONS OF THE UTERUS.

In a paper read before the British Gynecological Society, Dr. C. H. S. ROUTH came to the following conclusions on the treatment of flexions (*Medical Press*, July 6, 1887):

1. Where ordinary Hodge pessaries are used,—(a) No pessaries whatever should be used, until such time as all inflammatory or congestive symptoms have been removed, and this is a *sine quâ non* in all cases when the fundus uteri is tender or inflamed. (b) Particular care should be taken to insure an exact fit of such pessary to the affected person to prevent pressure on the fundus or bent angle of the flexed uterus. It should be removed for cleansing purposes, etc., every three or four months for a few days, but again replaced,—kept in for a year. A shorter period could never, or very rarely, cure.

2. In regard to intra-uterine stems,—(a) Whenever the canal is narrowed or obstructed at the point of flexion, an intra-uterine stem is essential. In no case, however, should it be allowed to press against or even touch the fundus. (b) Where the flexion is not very marked, the india-rubber stem may be used. If the flexion be great, it is best to support it by a buckle pessary, and an internal stem again within it. In such cases, however, the solid diverging stem or buckle pessary are preferable. (c) If the adhesions which force the uterus in a flexed position be strong, the india-rubber steel spring intra-uterine stem should be first tried. If the adhesions be too strong, oöphorraphy affords the only chance of cure. (d) Intra-uterine stems, whether with or without buckle pessary, should be kept in for six or eight months. (e) In cases of great subinvolution of the uterus, the stem should be thicker than in ordinary cases, and especially so if the flexion be very marked. (f) Neither suspension of the uterus nor shortening of the round ligaments should be practised in cases of great uterine enlargements or prolapse. The same objections hold in cases of firm and extensive adhesions, and great debility and relaxation of the ligaments. (g) In all cases with marked prolapse the buckle pessary is the safest. (h) If, after full trial of instruments, they either fail or produce great pain and inflammation, then Dr. Alexander's

operation may be tried, and failing that, Dr. Heywood Smith's or Dr. Imlach's, except only in the exceptional cases before mentioned.

THE TREATMENT OF LUPUS BY INJECTIONS OF CORROSIVE SUBLIMATE.

DR. IGINIO TANSINI, of Lodi (*Gazzeta degli Ospetali*, June 12), narrates the treatment of a case of lupus of the nose and face by means of repeated injections of corrosive sublimate. He began with a weak solution,—corrosive sublimate, 50 centigrammes; distilled water, 100 grammes. This produced no reaction of any kind. A stronger solution—corrosive sublimate, 1 gramme; distilled water, 100 grammes—was then used. This produced some tumefaction and œdema in the neighborhood of the punctures, and slight suppuration in some of them. Some fourteen or fifteen injections of a few drops were practised. Improvement soon became marked, and eventually all traces of the disease disappeared, the only marks left being those of the punctures in which suppuration had taken place. Dr. Tansini was led to try these injections by the following considerations: 1. That lupus is a form of tubercle. 2. That the bacilli are few, and have no tendency to diffuse themselves. 3. That corrosive sublimate has proved certainly destructive to bacilli. He claims advantages for this method on account of lessened pain and disturbance and superior cosmetic results. —*The Lancet*, July 9, 1887.

THE MANAGEMENT OF FÆCAL RETENTION UNCONNECTED WITH ORGANIC DISEASE.

♦ The following is a summary of an elaborate paper by DR. GEORGE DALTON HAYS, published in the *New York Medical Journal* for May 21, 1887:

In acute constipation the best remedies are clysters, salines, and castor oil; in those forms denominated "bilious," lavage, emetics, and abstinence, and the use of cholagogues. Impaction of the colon results from causes of a chronic nature, but is apt to develop acute symptoms. Our chief reliance here rests upon intestinal irrigation. This should be employed in the manner indicated. In chronic constipation a thorough trial of all the hygienic and mechanical aids should precede the use of drugs, and, where recourse to the latter has eventually to be made, such aids are always to supplement all other forms of treatment.

Medicines having a curative tendency should always be chosen in preference to those which merely relieve the symptoms. Enemata are also of great value here. Aloes, rhubarb, belladonna, strychnine, cascara, ipecac, physostigmine, ergot, and the occasional use of the salines are the most efficient remedies of this class. Various combinations and alterations of these produce effects not otherwise attainable, but it is essential to bear in mind that our remedies should be directed to the cause and not to its effect. In constipation of a chronic nature large fæcal accumulations may occur at any time, and no examination of a patient is complete which does not include a careful exploration of the colon through the abdominal walls.

CATHA EDULIS.

The use to which the leaves of *Catha edulis* are applied by the Arabs, and the accounts which have been given of their stimulating effects, naturally suggest the probability that they may resemble, in containing caffeine, the vegetable products that are used for similar purposes, such as coffee or tea, or, perhaps, have some resemblance to cocoa-leaves. A small quantity of the leaves of this plant, which are known in Arabia by the name of Gat or Kat, have been subjected to examination by DR. B. H. PAUL, who published his results in the *Pharmaceutical Journal and Transactions* for June 11, 1887.

On digesting the leaves with ether a very dark-colored tincture was obtained, of a deep bluish-green color by transmitted light when in a thin layer, and in larger masses brownish-red. By evaporating off the ether a very dark-green, waxy residue was left that was only partially soluble in alcohol. This appeared to consist chiefly of chlorophyll mixed with a waxy substance, and, after precipitating the chlorophyll from the alcoholic solution by lime, the filtrate gave no indications of the presence of caffeine.

The leaves, after having been treated with ether, were digested for some time with strong alcohol at a moderate heat, and on evaporating the clear tincture about ten per cent. of a dark-colored aromatic extract was obtained, for the most part soluble in water. The water-solution of it contained a considerable proportion of substance which formed a yellow precipitate with acetate of lead, and after that had been separated the clear liquor left, on evaporation, a brown, syrupy residue.

Treatment of this residue with chloroform failed to extract from it any caffeine, even after the addition of ammonia.

If the leaves had contained caffeine indications of its presence should have been obtained either in the ethereal or the alcoholic extract, and consequently it may be inferred that the leaves do not contain this substance. So far as he is able to judge from the results of his examination, Dr. Paul is disposed to think that the stimulating effects attributed to the leaves when chewed may be due to ethereal oil or some other aromatic and volatile constituent, but to determine this point a larger supply of the leaves would be required. One point to which reference may be made in a general way is the presence of a form of tannic acid in the leaves of *Catha edulis* closely analogous to that met with in tea, coffee, maté, and coca-leaves. It is, indeed, possible that the physiological action of these articles of food may be, in some measure, due to the astringent substances they contain, as well as to the presence of caffeine, theobromine, or cocaine; and, from this point of view, the further examination of those different analogues of tannic acid may be worth attention.

THE CAUSE AND TREATMENT OF FUNCTIONAL INSOMNIA.

At a recent meeting of the New York Neurological Society Dr. B. SACHS (*New York Medical Journal*, May 21, 1887) read a paper on the above subject. Under the term he included cases of insomnia, pure and simple, occurring in persons of the neurasthenic habit. He preferred to say neurasthenic rather than hysterical, for in his experience actual insomnia was less frequent in truly hysterical patients than in those suffering from cerebral or spinal neurasthenia. A number of typical cases were cited. The author thought that in the majority of such cases there was good evidence of disturbances in the cerebral circulation. As it had been found in animals that an increased activity of the cerebral circulation was accompanied by a deficient circulation in the peripheral parts, so in many cases of chronic insomnia cold extremities, pallor of the skin, and a scanty uterine flow pointed to deficient peripheral circulation, and in many of these cases there was weakness of the heart, with a weak pulse. Special attention was called to the simultaneous occurrence of insomnia and headache, and to the fact that as a rule the headache was of the paralytic migraine type.

The treatment of migraine and that of insomnia were similar in many respects. The author wished particularly to insist on the point that continued hypnotic medication was worse than useless. The good results obtained by him had been due to close attention to matters of general regimen, to the treatment of anæmia, and to the strengthening of the force of the heart's action by cold douches, by the regulation of exercise, and by the methodical performance of definite forms of active physical exercise, such as riding, rowing, and mountain climbing. Hypnotics were of use only at the outset of treatment; among these the reader mentioned chloral and bromides, to be given at night, or bromides alone, amorphous hyoscyamine, urethan, and paraldehyde. Their use should be discontinued as soon as a slight improvement was noticeable, and from that time onward general treatment was to be pushed vigorously.

THE ANTAGONISM BETWEEN MORPHINE AND ATROPINE.

In the *Deutsches Archiv für Klinische Medizin*, 40 Band, 5 u. 6 Heft, LENHARTZ, of Leipzig, contributes an exhaustive paper upon this subject, which we summarize as follows:

He was led by the symptoms in three fatal cases of opium-poisoning to question whether the result was caused by morphine alone or by the combined effect of the atropine given as an antidote with the morphine. He has collected one hundred and thirty-two cases of opium-poisoning, of which fifty-nine were treated by some preparation of belladonna, generally atropine; of these seventeen died,—a mortality of 28.8 per cent. He also reports seventy-three cases which were treated without any preparation of belladonna, the treatment being generally stimulants, and the use of compresses and baths of cold water. Of these cases only eleven died,—a mortality of fifteen per cent. The injurious effect of atropine is most frequently exercised upon the heart, whose action is depressed by the opium-poisoning, and still more by its antidote. It is on this account that the author advises against the use of atropine as an antagonist to opium. His conclusions he has stated as follows:

The physiological antagonism between atropine and morphine is not established by a single authentic observation.

The use of atropine is not to be considered a means from which even an improvement in

the symptoms of opium-poisoning may be expected.

The principle of antidoting a poison by the use of another poison like atropine results in unreliable dosage, which has been productive of great injury.

The circumstance that cures have followed the use of atropine does not prove the positive value of the method.

The prognosis of opium-poisoning depends upon the use or neglect of a rational, non-antidotal system of treatment.

The careful comparison of the mortality of the two methods shows that the mortality after the treatment by stimulants and without atropine is less than that with other methods. An analysis of the cases from which these conclusions are drawn gives the following facts:

We have seen that of the first group of fifty-nine cases seventeen died,—28.8 per cent. Of the seventy-three cases of the second group, eleven, or fifteen per cent., died. Of the first seventeen cases eleven were from opium and six from morphine; of the second eleven, six died of opium and five of morphine. Among the first fifty-nine, five were children up to eleven and one-half years, and one of these died; of the seventy-three of the second group seventeen were children, and of these two died.

The doses which were poisonous varied as follows: A boy, 4 years old, died after taking 1 drachm of tinct. opii. A little child died after taking 2 teaspoonfuls of another opium preparation. With adults, from $\frac{1}{3}$ to $\frac{1}{2}$ grain of morphine, and 2 drachms of opium preparation, were the smallest fatal doses; while $6\frac{1}{2}$ drachms of morphine and 10 drachms of laudanum were the largest poisonous doses taken. The pulse was accelerated in fifty-six cases, and in two-thirds of all cases was full, or moderately full; in twenty-five cases it was normal, or but little changed; in nineteen it was very weak. Respiration was twelve times quickened; in twenty-seven times it was stertorous; in twenty-two cases the breathing was much slower than normal; it was rarely normal. Spasm was observed in thirty-eight out of the one hundred and thirty-two cases. Convulsions,—trismus, opisthotonus, and general convulsions were observed in thirty cases,—22.7 per cent.,—and in twelve of the fatal cases. These convulsions occurred in twelve cases of morphine-poisoning, one of which was a child; they occurred in eighteen cases of opium-poisoning, of which four were children. Convulsive seizures of mild grade were ob-

served in two cases of morphine-poisoning and six cases of opium-poisoning.

In eighty-six cases contracted pupils were observed, without reaction, in all 91.3 per cent.; dilated pupils were seen in six cases,—6.5 per cent.; the mydriasis was reported in three instances, several hours after the poisoning was diagnosed!

From these observations he concludes that the condition of the pulse in opium-poisoning is one often changing; acceleration is most often present; less frequently weakness and irregularity. Respiration is generally retarded; changing respiration, somewhat accelerated, is not uncommon. Convulsions are more common than generally supposed; they generally occur among adults. The condition of the pupil agrees with the statement of Orfila, that in nineteen out of twenty cases contracted pupils were present.

In conclusion the author remarks regarding the experiments of Binz and Henbach, that the doses of opium which they gave to the dogs used in their experiments were not sufficient to bring the animals into as dangerous a condition as are human beings when they are poisoned. Atropine, as an antidote for such experiments, has not the effect which causes us to recommend its employment with the human subject. Moreover, the lessened arterial tension which these authors observed was not a source of danger for the animals; the cause of death being the convulsions, which resembled those caused by strychnine, and which caused the animal's death, in spite of the use of atropine.

A SIMPLE MODE OF PREPARING TAMPONS.

DR. N. W. CADY, of Logansport, Ind., writes to the *New York Medical Record* for July 16, as follows: "Some time since I hit upon a handy method of preparing tampons. When made in the ordinary way, tampons are usually not firm enough, and the knots tied in the retaining string often produce pain, or even slight ulceration. The implement which I use in preparing them is a bit of wire twelve inches long, ending in a loop or hook. A piece of strong linen thread is doubled, and then looped over the hook, the ends being secured at the other end of the wire by two or three half-hitches. Cotton, oakum, jute, or wool is now wound firmly around the wire and thread until the roll is from four to five and one-half inches long, and from one-half to three-

fourths, or seven-eighths of an inch in diameter. The thread is now released from the wire loop, and the wire withdrawn, leaving the thread in the centre of the roll. The roll is then formed into a ring by tying the ends of the thread together firmly. Making the roll two and one-half inches or less, and correspondingly thicker, a conical tampon may be made. Oakum or jute answers very well for the interior of the roll, but I prefer cotton for the outside."

TINCTURE OF SIEGESBECKIA ORIENTALIS IN RINGWORM.

Of the drugs now generally prescribed in the treatment of tinea in its several varieties, some are exhibited in the form of ointments, and ointments are always more or less disagreeable to use; others free from greasy annoyances give the patient more or less pain in the application. In the *British Medical Journal* for June 25, 1887, Dr. J. HUTCHISON refers to a preparation which he has been using for some time, and which is devoid of both these drawbacks, and is at the same time a speedy and reliable means of curing the disease.

Dr. Hutchison has used it in fifteen cases of ringworm; of these, eight were cases of tinea circinata, four of tinea sycosis, two of tinea tonsurans, and one of tinea versicolor. The site of the eight cases of tinea circinata was in six of them upon the neck, and in two upon the calf of the leg. None of the patients called upon me till the disease was well developed, when the red, raised, circular, bounding edge, and the pale central area with its branny desquamation, left little doubt of the diagnosis. The four patients who were afflicted with tinea sycosis all blamed a "foul shave" for their ailment. In all of them the disease was upon the chin, and presented the characteristic fig-like appearance. The two cases of tinea tonsurans showed the roundness of the diseased patches, the scaly eruption, and the brittleness of the hairs peculiar to that form of the trouble. The one case of tinea versicolor was also typical.

His prescription in all of them was the same, namely, equal parts of tincture of siegesbeckia and glycerin, and this he ordered to be well rubbed into the affected area night and morning. The drug appears to act both as a stimulant and a parasiticide, and the method of cure was for the diseased patch to become broken up into a number of smaller

patches, with sound skin intervening. These smaller patches became again broken up till they disappeared altogether, and in their place was left a red blush, as if the part had been struck a smart tap with a cane. This redness, however, only remained for a day or two. The two cases of tinea tonsurans were the most stubborn to give way, but even in their cases more frequent applications, and continuing the treatment over a longer period, brought about the result desired, and that, too, without resorting to epilation.

SOME OLD-TIME PRESCRIPTIONS.

In the *Medical and Surgical Reporter* for July 9, 1887, Dr. HARRISON ALLEN calls attention to a number of classical prescriptions which seem to be in danger of being forgotten. The first of these was published in Dr. Chambers's lectures in London, 1865, and is as follows:

℞ Tincturæ ferri sesquichloridi, ℥ii;
Strychninæ hydrochloratis, gr. ss;
Tincturæ digitalis, ℥i;
Misturæ camphor., ℥x.
Fiat mistura.

Sig.—Two tablespoonfuls twice daily.

Dr. Chambers states that he administered an ounce of the mixture twice a day, in a case of anæmia in which the eyeballs were prominent, and he dwells upon the significance of this form of anæmia seen in young women in whom there is excitement of the heart's action, retarded development of the sexual functions, and enlargement of the thyroid gland. This combination appears to act most happily in this condition. The iron is adapted to the anæmic condition, the strychnine is a tonic to the small blood-vessels and to the central nervous system, the digitalis is a heart-tonic, and the camphor is an antispasmodic. The remedy does not interfere with digestion. With watchfulness and care its use can be persisted in indefinitely. It is not necessary that all the symptoms included in the above category should be present in order that this remedy may prove efficacious. The recognition of a retarded state of development of the ovaries and associated organs, absence of the secondary sexual characters, anæmia, and a thyroid engorgement are sufficient.

A second formula, perhaps not as elegant as the foregoing, is the following:

R Hydrarg. bichlor., gr. iv;
Solve in spirit. rectific., ℥ii;
Decot. cinchonæ, ℥ii;
Mel rosæ,
Tinct. myrrhæ, aa ℥ii. M.
Et ft. gargarisma.

This prescription appears in the Institute of Surgery of Sir Charles Bell, and it would seem difficult to improve upon this formula for a mercurial wash for the ulcerated forms of syphilitic sore throat.

In prescribing it the patient should be directed to use a small quantity at a time, and to note its effects. If it prove to be too severe, he should add an equal quantity of water to each dose, which might be limited to a table-spoonful. If this prove to be irritating, it may be again diluted, until at last it can be easily borne. The patient should be encouraged to use the remedy as far as practicable in the form above given. If he is compelled to begin with the dilutions, he can be induced, after he is in a measure accustomed to the effects, gradually to return to the original strength of the remedy.

In employing an astringent for a gargle an admirable method employed by our seniors was, instead of using pure tannic acid, to introduce a native astringent substance known to contain the acid. As an example of this form, Dr. Allen gives a prescription known in Philadelphia as "Goddard's Gargle," as first introduced by Dr. Paul B. Goddard, and frequently prescribed by the late Dr. Francis Gurney Smith. It is as follows:

R Aluminis, ℥ii;
Cort. granati, ℥ss;
Petal rosæ rub., ℥i;
Mellis, ℥i;
Aquæ bull., ℥vi. M.

The mixture can be used without dilution, or with an equal quantity of water. It appears to present all the features required by an astringent wash to the throat. If increased strength is demanded it is better to direct an agent to be employed topically by the attending physician.

Another preparation, the uses of which can be made to subserve a great number of indications, is Fowler's solution of arsenic. Small doses of this preparation, say 2 or 3 drops twice a day for a period varying from one to six months, produce most gratifying results in those states of impaired health which appear to be due to an inheritance of a phase of malnutrition, and which is so evasive that it is difficult to give it a distinctive name.

Local diseases engrafted on such a condition will often resist remedies until arsenic, in the form of liquor potassæ arsenitis, is employed. Pharyngitis sicca, atrophic nasal catarrh, anæmia accompanying tertiary syphilis, are sometimes greatly improved, indeed to a degree far greater than it has been possible with any other agents, by these small doses of Fowler's solution.

HYDROSTATIC PRESSURE IN INVERSION OF THE UTERUS.

PROFESSOR MAX RUNGE, of Dorpat, having a case of inversion of the uterus, caused by a midwife pulling on the cord, which had been allowed to remain without medical advice for nine weeks, made several fruitless endeavors to effect reduction by manipulation and by distention of the vagina, by means of Braun's colpeurynter, which consists merely of an india-rubber ball with thin walls, provided, like Barnes's bags, with a tube and stop-cock. He then bethought himself of a plan recommended and practised successfully by Krukenberg,—viz., the application of considerable hydrostatic pressure to the vaginal canal, with the view of dilating the os uteri and of softening the inverted uterus itself. Professor Max Runge sprinkled the colpeurynter well with iodoform, and again introduced it, connecting it with a vessel of water hung at the height of about three feet eight inches above the bed. Communication between the colpeurynter and the water-vessel was kept open, the stop-cock not being turned off, and so a high degree of hydrostatic pressure was continually exerted, distending the vagina and the os and compressing the body of the uterus. Next morning the pain caused by the apparatus became unendurable, and the patient pulled it away from her. Upon examination, it was found that the fundus had retreated within the os, which was widely distended; there was still, however, a partial inversion, which was readily reduced with the finger. The uterine cavity was then washed out with a carbolic solution, and a tampon of iodoform wool introduced into it. The mucous membrane of the vagina showing signs of sloughing, it was well powdered with iodoform; ergot was also given. The parts were carefully dressed for some days, and the patient made a rapid recovery.—*The Lancet*, June 25, 1887.

A NEW THEORY OF RESPIRATION.

According to the Vienna correspondent of the *New York Medical Journal*, July 9, 1887, at a recent meeting of the Imperial-Royal Society of Physicians, PROFESSOR VON FLESCHL propounded a new theory of respiration, of which the following are the chief features. He had sought to ascertain the utility of the heart-beat. It would be most unreasonable, he said, to have such a motor force as that of the heart simply to drive the blood mechanically into the vascular system,—that work could be much better done by a gradually increasing *vis a tergo*, and the heart-beat was dangerous to life by the consequent variations in the blood-pressure. Why did so many persons die of apoplexy? Because of the great oscillations of the blood-pressure caused by the action of the heart. The heart-beat must, therefore, have another purpose than the merely mechanical act of keeping up the circulation. Referring to the familiar fact of the sudden setting free of chemical constituents as the effect of concussion, the speaker remarked that he had shown on a previous occasion that it was the beat of the heart that set carbonic acid free in the right ventricle. Now, oxyhæmoglobin was of such a stable constitution that the affinity of the tissues for oxygen was too feeble to enable them to withdraw it from the combination. But the blood, charged with oxyhæmoglobin, was subjected to energetic agitation in the left ventricle, and the oxygen was set free in the same way that carbonic acid was set free by the action of the right ventricle; the blood of the left ventricle no longer contained oxyhæmoglobin, but free oxygen. In the first volume of his "*Archiv*" Pflüger had discussed the mechanical influence to which the blood was subjected in the heart, and had described the agitation which it sustained there, but he had not emphasized this phase of it, and had considered the change of surface as the chief feature. The speaker remarked that it would be a mistake to suppose that the blood that came out by the aorta was the same that had been carried to the heart by the pulmonary veins. Both the hæmoglobin and the tissues had a certain affinity for oxygen, and the purpose of the heart-beat was to settle the matter in favor of the tissues. To sustain his theory, the speaker mentioned the following facts: The oxygen could not be set free from a solution of oxyhæmoglobin, at a temperature of from 0° to 10° Celsius, unless the solution was shaken energetically; agitation with a spoon was not sufficient, but it must be subjected to repeated and decided

shocks. Pflüger had known this fact, but he had not given it the correct interpretation. Approximately, one-third of the whole weight of the liver consisted of blood, the rest being parenchyma. Why, with the organ inundated with blood to this extent, was the hepatic artery so small in comparison with the size of the portal vein? Why did the tissue of the liver become necrosed when the hepatic artery was tied? These matters were explained by the speaker's theory. The blood of the hepatic artery contained free oxygen, whereas the oxygen of the blood of the portal vein, although it surpassed the other many times in quantity, was so combined with hæmoglobin that it could be of no use to the liver. It was known from the experiments of Claude Bernard, Stricker, and Albert that the blood of the left ventricle was cooler than that of the right ventricle by some tenths of a degree. This had been explained by the suggestion that the blood circulating through the lungs lost a part of its heat by evaporation and by contact with the inspired air. Heidenhain, however, had shown that this theory was not correct. He had caused animals to inhale air that had previously been heated and supersaturated with aqueous vapor, but nevertheless there was a difference in the temperature of the blood in the two ventricles. The speaker's theory gave the key to the true explanation. It was known that heat was evolved in every instance of oxygenation. In the lungs the blood still held its third part of oxygen in combination, and it was for this reason that it was warmer than the blood of the right ventricle. As to the left ventricle, cooling was due to the freeing of oxygen from its combination. In the aorta no considerable reoxygenation took place, for the blood coursing through that vessel still felt the force of the cardiac agitation, and it was interesting to note that the blood there was still cooler, by two-tenths of a degree, than that of the left ventricle. The speaker illustrated his theory with several further facts, and said that he would give the full details in a work to be published in October.

HOW TO GIVE INJECTIONS OF ERGOTINE.

In the *Centralblatt für Gynäkologie*, No. 28, 1887, BUMM describes the technique of injecting ergotine, which we condense, as follows:

Regarding the choice of a location for the injection, the writer is strongly opposed to the integument of the abdomen, which is so often chosen. He considers it an entirely

improper selection, and expresses his strong preference for the nates, where experience has shown that mercurials can be most conveniently injected. The solution must be injected directly into the muscles, and to accomplish this the needle should be introduced perpendicularly to the skin, and as deeply as its length will allow. Intramuscular injections are entirely absorbed twelve hours after injection, while subcutaneous injections are retained much longer. The choice of a proper solution is important. The fluid should be perfectly clear and liquid. It has been found that the greater part of the burning pain, of which patients often complain after these injections, is caused by the strongly acid reaction of the extract of ergot used. When this acidity is neutralized the virtue of the drug is unfortunately much impaired. A good preparation for injection should remain clear when almost neutralized by soda solution, not when the reaction is made alkaline. From his observations upon patients the writer concludes that the effect of the drug is not lessened by making the solution neutral. A second cause of the pain produced by injections is the strength of the solutions employed. A solution, 1 part of ergotine to 5 of water, is often recommended. The writer believes that solutions of five or ten per cent. are of more utility, and that in emergencies, when prompt action is demanded, two or three simultaneous injections of weaker solutions are better. The further advantage obtains that a dilute solution, distributed over a wider area, will be absorbed much more readily than a more concentrated solution retained in a smaller space. When a watery solution of from five to ten per cent. of a pure specimen of ergot is neutralized by soda, filtered until clear, and injected deeply into the nates, almost no after-effects are produced. A very trifling sensitiveness for a half or a whole day, with a little redness and swelling, is the most observed. The advantages of the nates over the skin of the abdomen as a place of injection are so great that the writer is positive in his recommendation.

USEFUL APPLICATIONS FOR INSECT-BITES.

BERNBECK has written a laborious essay upon this frequent and often insignificant ill, and proposes the following as the best applications which are known to him :

Elastic collodion, 10 parts ;
Salicylic acid, 1 part.

Also

Elastic collodion, 1000 parts ;
Bichlorid. hydrarg., 1 part.

To be used as soon as possible after a bite.

—*Pharmaceutische Post*, July 10, 1887.

THE PHYSIOLOGICAL EFFECTS OF COCAINE.

The above is the title of an elaborate paper by Mosso, of Turin, published in the *Archiv für Experimentelle Pathologie und Pharmacologie*, Band 23, Heft 3 u. 4, which we abstract as follows :

His first experiments were made with frogs, to test the effect of the drug upon the nervous system of cold-blooded animals. He found that in large doses cocaine paralyzed the spinal cord, while the motor and sensory nerves, in their peripheral portions, were yet intact. The conducting power of the cord was in abeyance, and the reflexes, as well as the other functions of the nerve-cells of the cord, were for the time abolished. Only in the last stages of poisoning by cocaine was increased irritability of the motor nerves observed. The lymphatic heart of the frog was of course paralyzed by the paralysis of the spinal cord. Regarding the general effect of cocaine upon warm-blooded animals, he observed that animals of the same kind differed greatly in their power to bear large doses of the drug. He found that in its effect upon the general nervous system the convulsions which it caused were not exaggerated reflexes, because they did not depend upon external causes. They originated in the nerve-centres from a temporary malnutrition, and spread through the muscles. It did not produce convulsions in cold-blooded animals. Death sometimes took place, with the symptoms of tetanus ; at other times, with a general paralysis, without especial convulsions. When the spinal cord was severed it was found that the cord alone, without the aid of the brain or the medulla, could excite strong convulsions of the muscles of the extremities, which exactly resembled the convulsions which cocaine produced in animals. The increased excitability of the cord was also attended by a rise in temperature. It was found that cocaine increased the frequency of respiration, and this was due, not to increased carbonic acid gas in the blood and the need for oxygen, but by a purely nervous stimulation which the drug exercised upon the nervous centres. The insuffla-

tion of cocaine in powder into the lungs resulted in an increased frequency in breathing also, and the conclusion was reached that cocaine is a direct respiratory stimulant. In small doses cocaine stimulated and accelerated the action of the frog's heart, and this effect persisted for some time after the blood containing the drug had left the heart. In large doses the heart was arrested in systole. The frequency of the heart's action in warm-blooded animals was not affected by small doses of cocaine; moderate doses produced a great acceleration, which sometimes became as high as three times the normal rate. In cocaine spasms the heart-beat was of course modified by the spasm. Regarding the effect of cocaine upon the pneumogastric nerve, it was found that not only the frequency but the vigor of the heart's contraction was altered. The increased frequency of the heart-beat was not caused by paralysis of the pneumogastric, for the nerve was found sensitive to the electric current after the use of very large amounts of cocaine. The drug lessens the susceptibility of the pneumogastric to electricity, but this effect does not persist, and disappears after even large doses if they are not renewed. The pneumogastric nerve does not lose its irritability, as shown by the fact that, after large doses have been given, the use of electricity on the nerve will influence respiration in its characteristic manner. Large doses of cocaine do not slow the heart's action. In its effect upon blood-pressure, doses of from $\frac{1}{4}$ to $\frac{1}{2}$ of a grain for each two pounds of body-weight increased blood-pressure in dogs; larger doses resulted in a lessening of blood-pressure. Great individual idiosyncrasies were observed. Cocaine retarded the fall in blood-pressure and lowering in body-heat, which usually follows severance of the spinal cord. In very large doses cocaine at first produced a lessening of blood-pressure; afterwards an increase. Cocaine was found to have a direct influence upon the blood-vessels. Experiments upon the circulation in extirpated organs of the body showed that in small doses, for example, $\frac{1}{100}$ per cent. of body-weight, it produced no marked effect upon the blood-vessels. Doses of $\frac{1}{100}$ per cent., $\frac{1}{80}$ per cent., and $\frac{1}{60}$ per cent. produced a well-marked paralysis of the blood-vessels of the extirpated organs. Upon the function of respiration it was found that cocaine, whether introduced into the lungs or the veins of an animal, produced a preliminary lessening in the frequency of breathing, followed by a persistent and characteris-

tic increase in the movements of respiration. Large doses produced a temporary paralysis, at times of the thorax, at times of the diaphragm. When the most intense and poisonous working of the drug is obtained, respiration is paralyzed. When the rectal temperature was above 106° F., increased respiration was observed as the precursor of respiratory paralysis and death. Artificial respiration is the best remedy for the respiratory paralysis of cocaine, as the heart continues to beat for some time after respiration ceases. Cocaine is of all known substances the most speedy and powerful increaser of bodily temperature. This increased temperature is not lessened by cutting the spinal cord. In determining the therapeutic uses and value of cocaine, experiments were made upon dogs whose skulls had been trephined and whose brains had been injured, and from these and other modes of research it was found that *cocaine was the best of all known excitants*, and this was confirmed by observations upon animals all of whose functions were rapidly failing. The most perfect antagonism was found to exist between chloral and cocaine, with the exception that the depression of temperature produced by chloral is not overcome by cocaine. An animal poisoned by chloral may be restored to consciousness and motion by cocaine, but no increase in the reduced body temperature occurs. The proportionate antagonism may be said to be $\frac{1}{3}$ of a grain of cocaine to each three pounds of body-weight, and 23 grains of chloral to each three pounds of body-weight. In attempting to antagonize the two drugs it must be remembered that in large doses both drugs paralyze respiration. The momentary paralysis of respiration produced by cocaine may be treated by artificial respiration. Fatal doses of chloral are endured when cocaine is first given. Chloroform and ether are direct antagonists by virtue of their subduing spasm and lowering temperature. When a patient is poisoned by cocaine and convulsions occur, with respiratory spasms, chloroform or ether may be given until the danger of spasm is passed, and chloral then used. The experimenter concludes that cocaine is of especial value in all narcotic poisoning by chloral, opium, morphine, and laudanum, where depression of the cardiac and respiratory centres exists. Also in chronic depressant poisonings from the bromides, or in spinal paralyses, the drug is indicated. It has all the advantages, without the poisonous nature, of strychnine.

*VESICAL INJECTIONS OF IODOFORM-
IZED ETHER IN REBELLIOUS
CASES OF CYSTITIS.*

In the *Lyon Médical*, June 5, 1887, M. A. CHANDELEUX reports some results obtained by him in the treatment of rebellious cases of cystitis by means of injections of a nearly saturated solution of iodoform in ether, or thirteen parts of iodoform to one hundred parts of ether. He thinks the choice of liquid a matter of considerable importance.

His first case so treated was a patient æt. 32, affected for eight months with a very painful tuberculous cystitis, giving rise to efforts at micturition every half-hour, and accompanied from time to time with a slight hæmaturia.

He first saw the patient in September, 1884. After having tried repeatedly instillations of nitrate of silver according to the method of Guyon (a measure which is generally successful in tuberculous cystitis), and without any other advantage than a slight diminution of the daily number of micturitions and a very slight modification of the pains, he determined to inject a small quantity of iodoformized ether. October 2 he injected 2 grammes (half a drachm) of the solution. Immediately the patient experienced atrocious pain, and for a half-hour he cried and complained. But quiet followed. During that day and the succeeding one the acts of micturition were a little more numerous than before the injection; but the following days they diminished in frequency, and five days afterwards there were not more than thirty or thirty-five in the twenty-four hours. The injections were repeated four times at intervals of five days, gradually increasing the amount until the last was 4 grammes (1 drachm). Each time the pain caused was less severe, the micturitions became less numerous, and finally decreased to ten in twenty-four hours, and without any uncomfortable accompanying sensation. The blood had entirely disappeared from the urine. Six months later the improvement was maintained.

In four other patients he had made use of this treatment. Only one of them had a cystitis of tuberculous origin, and in him also the instillations of nitrate of silver had had no appreciable results, for micturition continued to be painful, frequent (thirty to thirty-five times in twenty-four hours), and slightly sanguinolent at the moment of emission of the last drops of urine. The treatment was the same as in the preceding case, and the results were even more satisfactory.

An interesting phenomenon observed in this case was the distention of the bladder by the vaporization of the ether from the heat of the body.

The other cases submitted to this treatment were suffering, not from tuberculous cystitis, but from chronic cystitis of three, seven, and ten years' standing respectively, due in the first to gonorrhœal inflammation and in the two others to rheumatism.

These patients urinated from seventy to ninety-six times in twenty-four hours. The urine was lightly clouded, and contained a little muco-pus. A drop of blood was generally expelled after each act of micturition.

Nitrate of silver instillations led to some amelioration of the suffering, and reduced the number of micturitions to fifty in twenty-four hours, but could not carry the benefit any further. Then the injections of iodoformized ether were resorted to, as in the other cases. The pains, as in them, were severe at first, but progressively diminished, and one of these patients at the sixth injection was able to bear 6 grammes (1½ drachms) of the solution for twenty-two minutes. This patient was so far cured that he was obliged to urinate not more than twelve to fourteen times in twenty-four hours, instead of once every fifteen minutes, as at first.

The others urinate only eight times a day, and all are relieved of their pain in micturition.

The professor is disposed to regard the distention of the bladder by the ether vapor as being perhaps the most important element in the curative action thus described.—*St. Louis Courier of Medicine*, September, 1887.

A PHYSIOLOGICAL BASIS FOR AN IMPROVED CARDIAC PATHOLOGY.

The following is an abstract of a paper read by DR. T. WESLEY MILLS before the Canadian Medical Association at its recent meeting at Hamilton (*Canadian Practitioner*, September, 1887).

1. The views presented in this paper are such as grow mainly out of the writer's own and other recent investigations in cardiac physiology, and seem to be in harmony with the facts of clinical medicine and pathology. The principal thesis presented for the first time, and maintained in this paper, is to this effect: The nerve-centres are generators and reservoirs of nerve-force, which force is not only exerted through nerves during the func-

tional action, so called, of an organ or tissue, but is *constantly* being distributed to all the tissues of the body, according to their nutritive requirements. The functional action of a tissue is but a phase in its normal life; one of a cycle of changes essential to the well-being of that tissue, and without which its continued integrity is impossible. This view renders clearer the main part of the theory, which is that there is a *constant* outflow of nervous energy to the tissues, and not alone during the functional activity. It follows that functional use and the *highest* nutritive condition of a tissue are inseparable; but this view also explains why tissues do not perish outright, when not for some time functionally active, provided the centres presiding over them and the nerves distributed to them are intact; while they do generate in every instance when their nerves are divided. This explanation the writer would denominate the *neuro-trophic* theory, or better, the theory of *constant neurotrophic influence*. The evidence for this view is based upon common experience as to loss of appetite under depressing emotions; the results of functional and other disorders of the nerve-centres; the sequel of the section of the nerves of glands, muscle, etc. An explanation of the injurious effects on the heart of sexual excesses is given in the light of this theory. Athletic strain is intelligible only on some such view as this. We must recognize in man a *residual nerve-force*, exhaustion of which is followed by lasting injury. *Heart-failure falls under one general law for all the tissues*. The explanations hitherto given generally do not go beyond the remote cause (occasion). An explanation that is only mechanical can never be final for a living organism.

Certain peculiarities in cardiac disease are rendered much more intelligible when the *order of evolution* of the different parts of the heart in the animal series is considered. The oldest parts of the heart ancestrally considered have the greatest vitality.

It is also especially important both in etiology and treatment to remember the disproportionate development of the cerebrum in man.

2. The nerves of the heart now appear in a new light owing to recent researches. Influences from the nerve-centres reach the heart either by *sympathetic* nerve-fibres or *inhibitory* fibres proper. The vagus is really a *vago-sympathetic* nerve in all vertebrates thus far examined. The cardiac accelerators contain purely sympathetic fibres. The sympathetic

fibres that reach the heart, in whatever nerves found, tend to bring about destructive nutritive changes (catabolic metabolism), and so to exhaust the heart; while the inhibitory fibres affect constructive nutritive changes (anabolic metabolism).

The nerves of the heart exercise a *constant* influence over its nutrition. Section of these nerves leads to degenerative tissue-changes.

The views presented in this paper are not opposed to facts, while they furnish explanations that are both real and final.

BIBORATE OF AMMONIUM IN URIC ACID CALCULI.

The treatment of a paroxysm of renal colic is sufficiently plain, but the prevention of this paroxysm is a matter which has puzzled the master-minds of the medical profession from time immemorial. DR. WILLIAM J. CRITTENDEN states in the *Virginia Medical Monthly* for June, 1887, that he finds biborate of ammonium to be a drug possessing peculiar influence over uric acid calculi. In patients attacked with renal colic, caused by uric acid calculi, Dr. Crittenden prescribes 20-grain doses of biborate of ammonium every two hours until a free passage of urine takes place, and then every four hours until all ill feeling passes away. He then decreases the dose to 15 grains, three times a day, before meals, in a glass of flaxseed-tea, and continues this treatment for several months, discontinuing it for a day or two at a time every two weeks. When given for a length of time, he states that he has found it to be a good plan to combine it with lithiated extract of hydrangea in teaspoonful doses.

THE PHYSIOLOGICAL AND THERAPEUTICAL EFFECT OF HELLEBORUS VIRIDIS UPON THE HEART AND THE CIRCULATION OF THE BLOOD.

Helleborus viridis, of the family of the Ranunculæ, has been long known in medicine. In olden times many different species of hellebore were used as purgatives and emetics,—*H. viridis*, *orientalis*, *niger*, etc.

Prof. Schroff lays great stress upon the benefit obtained by the energetic action of the radix hellebori viridis upon the heart.

Further, Drs. Husemann and Marmé have extracted from the roots of different kinds of hellebore two glucosides,—helleborein and helleborin. The former, which is soluble in

water, in their opinion is analogous to digitalis ; the latter, however, which is easily dissolved in alcohol and not in water, is a narcotic.

From the proposition of Prof. S. P. Botkin, DR. N. ISCHISTOWITCH (*Centralb. f. d. Med. Wissen.*, July 9, 1887) experimented upon the effect of the radix hellebori viridis upon the heart and the circulation of the blood, using a liquid watery extract (extractum fluidum aquosum radicis hellebori viridis).

The principal results of his experiments upon frogs are as follows :

1. By subcutaneous injections of 0.1 to 0.6 c.c. 1 proc. of the watery solution of the extr. fluid. rad. hellebori vir. one noticed diminution of the number of heart contractions ; the contractions were fewer but more energetic.

Later, the ventricle during the dilatation begins to weaken, but not altogether, the contractions partake of a vermiform character, and at last the ventricle is brought to a stand-still in a strongly-contracted condition ; the exterior chambers are filled full of blood, contract, however, after a time, gradually decrease, and finally cease altogether. Before the entire cessation of the ventricle one contraction of the same will be two contractions of the outer chamber.

2. The changes in the action of the heart, described above, are observed by the previous severing of the sympathetico-vagus nerve and the injection of atropine. The observation of the diminution of the heart contractions was also made upon an excised heart with the assistance of the Williams apparatus for supplying the heart.

3. The excitability of the muscles of the heart increases at first and for a considerable time, after which the decrease begins.

This conclusion is supported by experiments made with the assistance of the Williams apparatus upon the point of the heart ventricle of an extracted heart.

The contractions of the point of the heart were periodically aroused by induction currents at definite intervals.

The minimum strength of the current was decided by the contraction of the point at each induction of the current.

4. The sympathetico-vagi possess the power to reserve the cessation of the heart until the entire cessation of the ventricle, after which irritation of the vagi prevents the contraction of the outer chambers.

To restore the heart to its normal, after using the remedy under discussion, an irritation of less strength is necessary than before the injection.

5. The blood-pressure in the arteries of the frog is increased through the extr. fluid. rad. hellebori vir.

This pressure is caused by the contraction of the smaller vessels (experiments of artificial blood circulation by the method of Prof. Setschenoff), and by the increase of the working power of the heart (experiments by the Williams apparatus).

The following results were obtained by experiments upon dogs :

1. Injections of from 0.1 to 1.5 c.c. per kilogramme of the weight of the body, of the watery solution of extr. fluid. rad. hellebori vir., cause the diminution of the beat of the pulse, and single heart contractions grow stronger ; the pressure of blood in the arteries is increased, also later begins an increase in the heart-beats and also a further increase in the pressure of blood.

After this the pressure decreases a little, the pulse becomes fluttering at times, which causes the heart to contract irregularly and suddenly to stop altogether.

2. The lessening of the beat of the pulse, which is characteristic of the first period of the effect of the medicine, can be prevented by the severing of the Nn. vagi or through injections of atropine.

3. The increase in the arterial blood-pressure is caused on one side by the contraction of the vessels of the body in consequence of the effect of our medicine upon the peripheric nervo-muscular apparatus of the vessels. (This has been proved by experiments in artificial blood circulation in amputated extremities.) But, on the other side, the increase in the pressure in the arteries during the increase of the strength of the heart contractions is dependent upon the increase of the action of the heart. This last I have proved with the assistance of Dr. G. Pawlow in experiments upon extracted hearts, with the exception of the greater and lesser circulation of the blood. (A description of this method will shortly appear in the *Centralblatt für Physiologie*.)

4. Experiments on artificial blood circulation through the cells of extirpated lungs prove that the action of our remedy causes the vessels of the lungs to contract.

5. The peripheric, as also the central vasodilator nerves, retain, after the poisoning by extr. fluid. rad. hellebori vir., their functional ability.

Clinical observations were made upon eleven cases of different heart-diseases at the period of a beginning failure of compensation.

The doses were from 10 to 20 drops of a one per cent. watery solution four or six times daily, or a teaspoonful of the infusion every two hours.

In six cases after use of the medicine there was strengthening of the pulse, lessening of the frequency of the pulse, and increased secretion of urine. All appearance of the failure of compensation disappeared rapidly, and the transudation was rapidly absorbed.

In two cases extr. fluid. rad. hellebori vir. and infusum adonid. vernalis given separately were without effect, but given together the condition of the patients improved rapidly.

In three cases our remedy gave negative results. In two of these cases the affection of the heart was accompanied by nephritis, and in the third case there was a complicated malformation of the heart, accompanied by pleuritic exsudativa.

DETAILS OF KOLISHER'S TREATMENT FOR TUBERCULOSIS.

We add to the account which we have already given of this method of treatment the following details as given in the *Centralblatt für die gesammte Therapie* for July, 1887: In cases where an opening has not yet been established the part is covered with a dressing of sublimate gauze for twenty-four hours, then thoroughly cleansed with soap and water, and finally with sublimate solution 1 to 1000. The injection is made with a Pravaz's syringe, having a platinum needle, which has been cleansed with a five per cent. solution of carbolic acid. The fluid is gradually injected until it thoroughly distends the tuberculous tissue, giving an elastic feeling on palpation; this is pushed until the tissue is tense, the portions not injected feeling less elastic and being depressed. The needle is inserted to its full length, and its passage into healthy tissue is marked by a sensation of resistance or grating; the tuberculous matter does not bleed as freely as does healthy tissue, and the latter is painful when injected in a greater degree than the diseased parts. The injections are painful, and morphia is frequently needed to quiet patients afterwards. These pains continue for several hours, and are often accompanied by fever of considerable severity, which persists for twelve or twenty-four hours. The part is at first covered with an antiseptic bandage, which is removed after five or six days, to be followed by a plaster-of-Paris bandage,

which is removed as needed. When the stage of reaction and hardening has become fully established, which generally occurs in from three to six weeks, passive motion and massage are employed to restore motion. Contractions and subluxations are treated as they demand. When in a week after injection abscesses form and break, the opening is enlarged and the cavity tamponed with gauze soaked in phosphate solution; over the tampon is placed an antiseptic dressing. These tampons are generally removed once in two days, as a profuse discharge of foul matter ensues. When the cavity has filled with healthy granulations they are treated with nitrate of silver and iodoform, as is usual in surgery. Even in these cases careful after-treatment may secure motion. In cases of necrosis the same treatment is employed. Cold abscesses are laid open, scooped, and tamponed with calcium phosphate gauze, and the edges are often freshened and sutured after Kocher's method, which lessens the scar produced. When tubercular granulations have reached the surface of the body the point of exit is enlarged, the edges freshened, the cavity tamponed with gauze, and the cavity injected with the solution; if the granulations are very torpid the caustic solutions of calcium phosphate are employed. Two cases of well-marked tuberculous fistulæ were treated with good success. Tuberculous skin-ulcers were bandaged with gauze soaked in phosphate solutions, and healed rapidly. The number of tuberculous lymphomata treated was too small to admit of reaching any conclusion. FREUND has experimented with solutions of various substances for Kolischer's use, calcium chloride, calcium carbonate, and water charged with saline matter, giving no results. Solutions of acid calcium phosphate were then used, and after many experiments two solutions were united containing one and two per cent. of free phosphoric acid. The following solution is generally used for injection:

Calci. phosphor. neutral., 5 parts;
Aqueæ dest., 50 parts;
Acid. phosph., q. s. ad solut. perfect.
Filtrea, adde
Acid. phosphor. dil., $\frac{1}{10}$ part;
Aqueæ dest., q. s. ad 100 parts.

The same solution is generally used for impregnating gauze. In especially torpid processes a double quantity of phosphoric acid is added, to the proportion of two per cent. The solutions used for injection are first sterilized.

AN IMPROVED CAUSTIC PASTE.

DR. JULES FELIX, of Brussels, having found existing caustics unsatisfactory from the great pain which is caused by their application, from the difficulty of limiting their action precisely to the part desired, from their deliquescence and from various other causes, has devised a form of caustic paste which he has been using for some time past with the best results. It does not cause severe pain or set up any general reaction; the eschar is hard and well defined, so as to be easily detached. It is also a powerful antiseptic and hæmostatic. It is not deliquescent, but keeps its consistence, which is that of putty, well, and so lends itself easily to manipulation. The hands should be wetted when applying it. They are not in any danger of being acted on. The paste is allowed to remain for from six to twenty-four hours according to the amount of eschar which it is desired to form. The formula for the paste is as follows: Mix in a mortar the following substances in powder: Starch, 37 grms.; wheat flour, 112 grms.; bichloride of mercury, 1 grm.; dry chloride of zinc, 110 grms.; iodol pure, 10 grms.; croton chloral, 10 grms.; bromide of camphor, 10 grms.; crystallized carbolic acid, 10 grms. Then add gradually a sufficient quantity of distilled water to form a homogeneous paste, without lumps, of the consistence of putty. This paste will keep an indefinite length of time.—*Lancet*, August 6, 1887.

ANTIPYRIN SUBCUTANEOUSLY IN PLACE OF MORPHINE.

GERMAIN SÉE has reported to the Academy of Sciences his observations in the use of antipyrin subcutaneously in place of morphine. The ready solubility of the drug in water makes this mode of its administration easy. 8 grains of antipyrin may be dissolved in an equal amount of distilled water, and given as one dose. A feeling of generally-increased tension follows, which is soon succeeded by a remission of pain, from whatever cause. None of the ill after-effects so often produced by morphine follow the administration of antipyrin. Neither somnolence nor excitability are produced by antipyrin, and it apparently possesses not only the power of checking pain, but of curing it. The diseases in whose treatment it may be employed are many. Excellent results were obtained by the writer in the treatment of acute articular rheumatism by

two or three injections of 8 grains of antipyrin, aided by the further use of 45 grains taken daily for some time. Acutely painful gout, chronic gout, and rheumatism have been very favorably modified by this remedy. In neuralgias, lumbago, migraine, and tabes it has cured pain. One injection, and from 45 to 60 grains taken internally, were especially successful in tabes. In patients suffering from biliary calculi the drug gives the best results, without disturbing the intestinal functions. In this respect it is greatly superior to morphine, which deranges the secretions. In nephritic colic it is equally valuable, as it relieves the pain without deranging the secretion or voiding of urine. In painful affections of the heart and angina pectoris antipyrin gives the greatest relief; attacks of angina pectoris are diminished in number and violence by these injections. In asthma and severe dyspnœas of whatever origin antipyrin checked the paroxysm most promptly. It was used in these cases during the attack itself, when iodide of potassium had failed to break up the disease, and the patient had been accustomed to have recourse to morphine for relief. Antipyrin promotes and facilitates expectoration in asthma, without suppressing the bronchial secretions. So far, in the writer's experience, there is not a disease or complication where antipyrin cannot replace morphine in the cure of the pain produced by disease. The advantages to be gained by society in using a drug for which a habit will not readily be formed, as for morphine, are very great. Antipyrin diminishes the reflex excitability of the spinal cord, without producing the sensations of intoxication which morphine causes.—*La France Médicale*, No. 86, 1887.

BORATE OF AMMONIUM IN PHTHISIS.

Borate of ammonium has been found by PROF. LASHKEVICH of great value in phthisis. Internally, he gives 5 grains three times a day in solution, either alone or combined with codeia, hyoscyamus, or other sedatives. This he finds produces a marked effect on the expectoration, and in some cases where the affection had only reached an early stage a distinct diminution of the pyrexia was observed. The solution was also employed with advantage as an inhalation (in the form of spray?), reducing the expectoration and alleviating irritating and painful conditions of the mouth and throat.—*Lancet*, August 6, 1887.

THE INTERNATIONAL MEDICAL CONGRESS.*

AN EXPERIMENTAL CONTRIBUTION TO INTESTINAL SURGERY, WITH SPECIAL REFERENCE TO THE TREATMENT OF INTESTINAL OBSTRU- TION.

THE following is an abstract of a paper read before the Section in General Surgery by DR. NICHOLAS SENN, of Milwaukee, Wis. :

1. ARTIFICIAL INTESTINAL OBSTRUCTION.—STENOSIS.—(a) *Partial enterectomy and longitudinal suturing of wound.*—Traumatic stenosis from this cause becomes a source of danger from obstruction or perforation in all cases where the lumen of the bowel is reduced more than one-half in size. Longitudinal suturing of wounds on the mesenteric side of the intestine should never be practised, as such a procedure is invariably followed by gangrene and perforation by intercepting the vascular supply to the portion of bowel which corresponds to the mesenteric defect.

(b) *Circular Constriction of Intestine.*—The immediate cause of gangrene in circular constriction of a loop of intestine is due to obstruction of the venous circulation, and takes place first at a point most remote from the cause of the obstruction.

2. FLEXION.—(a) *Flexion produced by Partial Enterectomy and Transverse Suture of Wound.*—On the convex surface of the bowel a defect an inch in width can be closed by transverse suturing without causing obstruction by flexion. In such cases the stenosis is subsequently corrected by a compensating bulging, or dilatation, of the mesenteric side of the bowel. Closing a wound of such dimensions on the mesenteric side of the bowel by transverse suturing may give rise to intestinal obstruction by flexion, and to gangrene and perforation by seriously impairing the arterial supply to, and venous return from, the portion of bowel corresponding with the mesenteric defect.

(b) *Flexion caused by Inflammatory and other Extrinsic Causes* gives rise to intestinal obstruction only in case the functional capacity of the flexed portion of the bowel has been diminished or suspended by the causes which have produced the flexion, or by subsequent causes independently of the flexion.

3. VOLVULUS.—As in flexion, a volvulus gives rise to symptoms of obstruction when

the causes which have given rise to a rotation upon its axis of a loop of bowel have at the same time produced an impairment or suspension of peristalsis in the portion of bowel which constitutes the volvulus, or when a diminution or suspension of peristalsis follows in consequence of the rotation.

4. INVAGINATION.—Accumulation of intestinal contents above the seat of invagination is one of the most important factors which prevents spontaneous disinvagination, and which determines gangrene of the intussusciptions.

Spontaneous reduction is not more frequent in ascending than descending invagination.

The immediate cause of gangrene of the intussusciptions is obstruction to the return of venous blood by constriction at the neck of the intussusciptions. Ileo-cæcal invagination, when recent, can frequently be reduced by distentions of the colon and rectum with water, but this method of reduction must be practised with great care and gentleness, as over-distention of the colon and rectum is productive of multiple longitudinal lacerations of the peritoneal coat, an accident which is followed by the gravest consequences.

The competency of the ileo-cæcal valve can only be overcome by over-distention of the cæcum, and is effected by a mechanical separation of the margins of the valve; consequently it is imprudent to attempt treatment of intestinal obstruction beyond the ileo-cæcal valve by injections per rectum.

ENTERECTOMY.—Resection of more than six feet of the small intestine in dogs is uniformly fatal. The cause of death in such cases is always attributable to the immediate effects of the trauma. Resection of more than four feet of the small intestine in dogs is incompatible with normal digestion, absorption, and nutrition, and often results in death from marasmus.

In cases of extensive intestinal resection the remaining portion of the intestinal tract undergoes compensatory hypertrophy, which, macroscopically, is shown by thickening of the intestinal coats and increased vascularization.

PHYSIOLOGICAL EXCLUSION.—Physiological exclusion of an extensive portion of the intestinal tract does not impair digestion, absorption, and nutrition as seriously as the removal of a similar portion by resection.

Fæcal accumulation does not take place in the excluded portion of the intestinal canal.

The excluded portion of the bowel undergoes progressive atrophy.

* The following abstracts of papers read before the different sections of the International Medical Congress are selected from the report furnished by the *New York Medical Record*.

CIRCULAR ENTERORRHAPHY.—A modification of Jobert's invagination-suture, by lining the intussusceptum with a thin, flexible rubber ring, and the substitution of catgut for silk sutures, is preferable to Czerny-Lembert sutures.

The line of suturing on neck of intussusciens should be covered by a flap or graft of omentum in all cases of circular resection, as this procedure furnishes an additional protection against perforation.

In circular enterorrhaphy, continuity of the peritoneal surface should be secured where the mesentery is detached by uniting the peritoneum with a fine catgut suture before the bowel is united, as this modification of the ordinary method furnishes better security against perforation on the mesenteric side.

INTESTINAL ANASTOMOSIS.

The formation of a fistulous communication between the bowel above and below the seat of obstruction should take the place of resection and circular enterorrhaphy in all cases where it is impossible or impracticable to remove the cause of obstruction, or where the pathological conditions which have given rise to the obstruction do not constitute an intrinsic source of danger. Gastro-enterostomy and jejuno-ileostomy should always be made by approximation with partially or completely decalcified perforated bone-plates.

In making an intestinal anastomosis for obstructions in the cæcum or colon, the communication above and below the seat of obstruction can be established by apposition with decalcified perforated bone-plates, or by lateral implantation of the ileum into the colon or rectum. An ileo-colostomy, or ileo-rectostomy, by approximation with decalcified perforated bone-plates or lateral implantation should be done in all cases of irreducible ileo-cæcal invaginations where the local signs do not indicate the existence, or occurrence, of gangrene and perforation. In all cases of threatened gangrene and perforation the invaginated portion should be excised, both ends of the bowel closed, and the continuity of the intestinal canal restored by making an ileo-colostomy by approximation with perforated decalcified bone-plates or by lateral implantation. The restoration of the continuity of the intestinal canal by perforated approximation-plates, or lateral implantation, should be resorted to in all cases where circular enterorrhaphy is impossible on account of the difference in the size of the lumina of the two ends of the bowel.

In cases of multiple gunshot wounds of the

intestines involving the lateral or convex side of the bowel, the formation of intestinal anastomosis by perforated decalcified bone-plates should be preferred to suturing, as this procedure is equally, if not more, safe and requires less time.

ADHESION EXPERIMENTS.—Definitive healing of an intestinal wound is only completed after the formation of a net-work of new vessels in the product of tissue-proliferation from the approximated serous surfaces. Under favorable circumstances quite firm adhesions are formed between the peritoneal surfaces within six to twelve hours which effectually resist the pressure from within outward. Scarification of the peritoneum at the seat of approximation hastens the formation of adhesions and the definitive healing of intestinal wounds.

Omental grafts, from one to two inches in width, and sufficiently long to completely encircle the bowel, retain their vitality, become firmly adherent in from twelve to eighteen hours, and are freely supplied with blood-vessels in from twenty-four to forty-eight hours. Omental transplantation, or omental grafting, should be done in every circular resection, or suturing of large intestinal wounds, as this procedure favors the healing of the visceral wound and furnishes an additional protection against perforation.

The speaker presented some valuable specimens in which the operation had been performed on dogs; these specimens fully illustrated the value of the method advocated, and its entire feasibility, the union in some of these specimens being most remarkable. He called attention to its use in stenosis of the pyloric orifice. The duodenum or the first convenient coil of intestine being connected with the stomach by the method advocated, adhesions would form in from fourteen to twenty-four hours.

The adhesions in the specimen shown were wonderfully firm and strong.

ARTIFICIAL AND COMBINED DRAINAGE OF THE BLADDER, KIDNEYS, AND UTERUS THROUGH THE VAGINA, WITH AND WITHOUT GRADUATED PRESSURE.

In this paper, read before the Section in Gynæcology, DR. NATHAN BOZEMAN, of New York, described an instrument which he had devised recently. This draws the uterus away from the mucous membrane, and in the most perfect manner. He has also been able to combine in the same instrument drainage with the dilatation of the cicatricial tissue of

the vagina. The form of the instruments which concerns us here is intended for drainage alone, and he has called them intra-vaginal and vulvo-vaginal drainage-supports. The intra-vaginal instrument is applicable in most cases to all positions of the body. The vulvo-vaginal form is suited to the recumbent position, and to cases where the perineum is lacerated. These can be introduced and removed by the patient when necessary. They are small and simple, free from angles and sharp bodies, are readily kept clean, and excite no discomfort or irritation of the vagina. They do not press on the rectum or vagina, nor do they interfere with locomotion.

The author closed his paper with the following conclusions:

1. The importance of completion of the operation for fistula has not been duly appreciated. This forms, in many cases, the principal difficulty in the successful performance of the operation for the closure of the fistular opening. In other cases, when the fistula is cured, but the complications left without treatment, they lead sooner or later to the death or suffering of the patient. The greatest care should therefore be taken to discover and remove them.

2. Kolpokleisis, occlusion of the os uteri, and incision of the cervix in the bladder or rectum, are unjustifiable operations. They destroy the functions of the generative organs, lead to cystitis, then form venereal and vesicular calculi, pyelitis, and other diseases. Moreover, they are unnecessary. By means of the preparatory treatment of the complication by the aid of his button-suture and his dilating speculum, the author has been able to overcome all the difficulties which have been described as indications for operation.

3. The association of combined drainage in the dilatation of the vagina is a great improvement. The inconvenience and evil effects of incontinence of urine are thereby lessened, and the duration of the treatment shortened by the more rapid healing of the incisions and the formation of less cicatricial material in the reparative process.

4. We now propose a means of palliating the suffering due to incontinence of urine in a small proportion of cases of fistula which are incurable by this method,—even the dangerous one of kolpokleisis. Dr. Bozeman believes that some form of drainage may be instituted in every case, and the patient may be thus restored to enjoy life and the performance of its duties.

5. The possession of a system of combined

drainage will widen the scope of the operation of kolpo-cystotomy, done for cystitis, by removing the evils of incontinence of urine, now the chief objection to its performance.

6. Finally, the operation which Dr. Bozeman calls kolpo-urethro-cystotomy, followed by the exploration and treatment of the disease of the ureters and pelvis of the kidney, appears to have a brilliant future before it. In the treatment of pyelitis, renal calculi, and obstruction of the ureters, it will restrict within narrow limits the operation of nephrotomy and nephrectomy.

THE USE OF THE VAGINAL TAMPON IN PELVIC INFLAMMATION.

DR. W. W. POTTER, of Buffalo, N. Y., read a paper with the above title before the Section in Gynæcology, of which the following is an abstract:

A married woman, 22 years of age, came under the author's care about a year ago, with a previous history of abortion, which happened eight months before, from which time her invalidism dated. Upon his first examination, early in June, he found great tenderness of the intra pelvic organs and tissues, with partial fixation of the womb. The left tube was enlarged, and presented a banana-shaped mass to the touch, while the surrounding cellular tissue was more or less hard and tense. This finally grew soft, and late in August pus was discharged through the uterus, after which the tube diminished in size. There was relief from pain, and the general health improved. The improvement continued until November, when the tube again grew tender and swollen; but another discharge of pus soon brought relief again. From this time onward the gain was uninterrupted, and she was dismissed cured on April 1, 1887.

The treatment consisted in the regular and systematic tamponnement of the vagina twice a week, copious vaginal lavements of hot water, frequently administered, and constitutional measures, principally of iron and arsenic. The vagina was insufflated just prior to each packing with iodoform, bismuth, mineral earth, or other powder, and then small pledgets of cotton, wool, or jute were introduced in sufficient numbers to make gentle, firm, and even pressure, as well as afford comfortable support. Though there was much more of detail, he said these were the essentials of the management, and their

continuous employment for a period of nine months brought recovery.

Reference was made to the advancement gained of late in the differentiation of pelvic diseases of women, whereby the domain of gynecological therapeutics had been so enlarged that it was no longer possible to group all the ailments of woman under the inexact and misleading heads, "ulceration," "prolapse," and "inflammation."

One of the important consequences of this more accurate classification of pelvic disease had been to invite surgical aid and interference in regions previously considered unsafe for the knife, and for maladies hitherto regarded incurable. The road to fame was so direct through the open gateway of a brilliant abdominal section that it was just possible that some ambitious men had removed an innocent ovary or unoffending tube, now and then, to obtain a "record" as spayers of women. He would not disparage the work of Battey, Tait, Hegar, Goodell, and others in this field, for he believed it of inestimable worth, nor would he deny that excision was often necessary; but, on the other hand, he thought the appendages might often be saved by timely and judicious management. The case reported, one of a number he had seen of a similar nature, was sufficiently typical to illustrate his purpose, and from which the following deductions might fairly be drawn:

1. That many cases of disease of the uterine appendages might be arrested in their progress and diverted to successful issue without operation by appropriate treatment resorted to in their earliest stages

2. That the early employment of regular, prolonged, and systematic vaginal tamponnement afforded one of the safest, surest, and simplest ways of preventing the ravages, in whole or in part, of the maladies in question, and of averting that mutilating of the sexuality of women consequent upon excision.

VAGINAL TAMPONNEMENT.

This occasion gave him the opportunity of offering some remarks upon the employment of vaginal tamponnement in the treatment of vaginal disease in general, a subject which was again creeping into medical literature through society discussions and papers.

In order to obtain the full benefits of this treatment, it was of the first importance that the packing be well done; that it be so placed as to afford ample support, give secure rest to the parts, make firm pressure, and not become dislodged during its wearing; while, at

the same time, it must not produce discomfort, interfere with the functions of the pelvic organs, nor cause irritation in the least degree.

In giving instructions as to its use, he states the tampon must be multiple, and not made up of a single wad or mass, as was too often done.

For the past ten years he has made systematic use of the knee-chest posture in the reduction of pelvic visceral displacements and of the multiple tampon in that connection, while latterly he had also employed them in the treatment of pelvic inflammations, the whole comprising many hundred cases. As a result of this experience he had reached the following conclusions:

1. In retro-deviations of the uterus the reposition of the organ should be made in the genu-pectoral posture without the aid of any other repositor than the finger; it should then be shoved up and held in place by the multiple tampon. This treatment should always precede the employment of a pessary for a longer or shorter period, according to the peculiarities of the case.

2. The foregoing applies with equally cogent force to prolapses and inflammations of the ovaries whenever these principles can be suitably adjusted to such cases.

3. In abrasions, erosions, and ulcerations of the os, in the hyperplastic womb, in subinvolution, in cystocele, in rectocele, and in all conditions of disturbed or impaired nutrition of the pelvic organs, it affords a most efficient form of preparatory or curative treatment, tending to give the organs rest, restore their tone, deplete engorgement, remove blood-stasis, improve locomotive power, and arrest retrograde tendencies in general.

4. In pelvic inflammations, whether of cellular, peritoneal, tubal, or other origin or involvement, it will often change their current or arrest progress, prevent suppuration or abridge its ravages, and thus often guide to a successful issue without a final appeal to a formidable, and perhaps dangerous, operation.

HOT WATER IN THE TREATMENT OF EYE-DISEASES.

DR. LEARTUS CONNOR, of Detroit, Mich., read a paper with the above title before the Section in Ophthalmology.

Dr. Connor stated that that remedy was sought after which would most certainly induce, first, good feeding of the tissue; second,

removal of morbid products and morbid agents; and, third, the promotion of speedy repair. Such an agent is hot water in a great variety of eye-affections, such as mild catarrhal and phlyctenular conjunctivitis, corneitis, affections of the sclera and iris, and even, in some cases, retinal hyperæmia. In iritis, where the pupil refuses to respond to mydriatics, hot water will exert a marked effect in assisting dilatation of the pupil. Similar beneficial results in reducing inflammatory action had been noticed by him in catarrhal and purulent ophthalmia, in relieving the pain in glaucoma and acute dacryocystitis.

There is no morbid state of the eye on which it may not exert beneficial influence. The results reported by divers observers vary with the different modes of using it. The water should be as hot as the end of the forefinger will bear without discomfort. The method preferred by the essayist was to take a common tumbler, fill it to the brim with hot water, and, inclining the head slightly forward, apply the rim of the tumbler to the side of the nose and to the brow and cheek about the eye, which brings the eye itself actually into the water. The amount of water loses its heat slowly, and does not require frequent changing, and the eye may be kept in hot water with very little trouble for hours at a time. Antiseptics may be added, and the remedy is easily attainable with means for application. It is safe without the watchful care of the physician, while moist heat by any solid substance, as poultices, should never be used except under the direct supervision of the attendant.

Poultices are unsafe and unreliable means of applying heat to the eye; also dirty, especially on denuded surfaces. Compresses are less objectionable, and may be used as a substitute for hot water.

Local effects: 1. Contraction of blood-vessels in and about the eye. Controls hemorrhages better than cold water, and blanches the tissues in conjunctivitis, blepharitis, phlyctenulæ; and after the use of hot water the ophthalmoscope shows the retinal vessels to be reduced in size. In one case where drawings were made of the vessels before and after, the difference was very marked, and the relief of retinal congestion and improvement of vision very noticeable.

The temperature of the water must vary with the sensations of the patient. The tissues should not be exhausted.

2. Hot water will wash away or destroy all morbid secretions or excretions. At a

temperature of 132° F. it destroys the bacillus of anthrax and many others, and many eyes can bear a somewhat higher temperature.

3. It promotes the healthful activity of reparative tissue or protoplasm.

4. It exerts direct power in relieving muscular fatigue and spasm.

FEVER, ITS CAUSES, MECHANISM, AND RATIONAL TREATMENT.

DR. AUSTIN FLINT, LL.D., of New York, delivered a general address with the above title, in which he reached the following conclusions:

1. Fevers, especially those belonging to the class of acute diseases, are self-limited in their duration, and are due each one to a special cause, a micro-organism, the operation of which ceases after the lapse of a certain time.

2. We are as yet unable to destroy directly the morbid organisms which give rise to continued fevers; and we must be content, for the present, to moderate their action and to sustain the powers of resistance of patients.

3. The production of animal heat involves oxidation of parts of the organism or of articles of food, represented in the formation and discharge of nitrogenized excrementitious matters, carbonic acid, and water.

4. As regards its relations to general nutrition and the production of animal heat, water formed in the body by a process of oxidation is to be counted as an excrementitious principle.

5. Fever, as observed in the so-called essential fevers, may be defined as a condition of excessive production of heat, involving defective nutrition or inanition, an excessive production and discharge of nitrogenized excrementitious matters and carbonic acid, with waste and degeneration of the tissues, and partial or complete suppression of the production and discharge of water.

6. Aside from the influence of complications and accidents, the ataxic symptoms in fevers, the intensity and persistence of which endanger life, are secondary to the fever and are usually proportionate to the elevation of temperature. These symptoms are ameliorated by measures of treatment directed to a reduction of the general temperature of the body.

7. The abstraction of heat by external cold and the reduction of temperature by antipyretics administered internally, without affecting the special cause of the fever, improve

the symptoms which are secondary to the pyrexia.

8. In health, during a period of inanition, the consumption of the tissues in the production of animal heat is in a measure saved by an increased production and excretion of water.

9. In fever, the effects of inanition, manifested by destruction and degeneration of tissues, are intensified by a deficient formation and excretion of water.

10. Alimentation in fever, the object of which is to retard and repair the destruction and degeneration of tissues and organs, is difficult mainly on account of derangements of the digestive organs; and this difficulty is to be met by the administration of articles of food easily digested, or of articles in which the processes of digestion have been begun or are partly accomplished.

11. In the introduction of hydrocarbons, which are important factors in the production of animal heat, alcohol presents a form of hydrocarbon which is promptly oxidized, and in which absorption can take place without preparation by digestion.

12. Precisely in so far as it is oxidized in the body, alcohol furnishes matter which is consumed in the excessive production of heat in fever, and saves destruction and degeneration of tissue.

13. The introduction of matters consumed in the production of heat in fever diminishes, rather than increases, the intensity of the pyrexia.

14. As the oxidation of alcohol necessarily involves the formation of water and limits the destruction of tissue, its action in fever tends to restore the normal processes of heat production, in which the formation of water plays an important part.

15. The great objects in the treatment of fever itself are to limit and reduce the pyrexia by direct and indirect means; to limit and repair destruction and degeneration of tissues and organs by alimentation; to provide matters for consumption in the abnormal production of heat, and thus to place the system in the most favorable condition for recuperation after the disease shall have run its course.

TREATMENT OF FRACTURES OF THE MAXILLÆ WITH MODIFIED INTER-DENTAL SPLINT.

DR. WILLIAM CARR, New York, N. Y., gave a clinic on the treatment of fracture of the maxillæ with modified interdental splint,

before the Section in Dental and Oral Surgery.

The majority of fractures of the inferior maxilla occur in the body rarely at the symphysis menti, but usually directly anterior or posterior to the mental foramen. A noticeable fact in connection with these fractures is that the victim rarely applies for treatment for several days succeeding the injury. He realizes that some of his teeth are loosened, and also that he is painfully bruised, but does not seek surgical aid until he becomes alarmed by the increased inflammatory condition of the parts. There is but little difficulty in establishing a correct diagnosis, as usually the following symptoms are present,—great pain in the effort to open and close the mouth, swelling, crepitus, inflammation, inability to masticate, and marked irregularity of the teeth.

Treatment.—It is identical with that of other fractures,—namely, to bring the parts into apposition and retain them firmly until ossification is completed. For treatment of fractures of the maxillæ there is nothing superior to the interdental splint. When properly adjusted, speedy union may be secured without deformity of the jaw or irregularity of the teeth. Before taking the impression a careful examination of the parts should be made. Loose teeth and spiculæ of bone should be removed, and the parts should then be brought as nearly as possible to their normal position. An accurate impression should be made with impression-compound or wax. The material used should be as warm as the patient can bear it, in order to prevent unnecessary pain, and also to prevent further displacement of the parts. The splint is made of vulcanite, and covers all the teeth of the lower jaw, and all the teeth posterior to the canine in the upper jaw, leaving a space of about three or four lines through which the patient may receive nourishment. Small holes are drilled in the splint over the grinding surface of each molar for the purpose of ascertaining whether its adjustment is proper.

The splint should first be adjusted to the sound jaw, then gently bring the fractured jaw into position until it has passed about two-thirds of the length of the teeth, then with a quick, firm motion bring the parts into position. Next apply a four-tail bandage, which should be retained from three to five days; after this time, in the majority of cases, it may with safety be removed during the day, but should be replaced at night until the removal of the splint. The patient should be furnished with an ordinary rubber syringe,

and instructed to keep the mouth thoroughly cleansed. For disinfectants the author uses peroxide of hydrogen, three per cent. solution, or a solution of bisulphate of sodium in the proportion of 3i to 3i of water.

In ordinary cases the splint should be retained for three or four weeks, according to the physical condition of the patient, unless unforeseen complications should arise. The application of the splint, combined with thorough cleanliness, will usually be all the treatment required.

The advantages, besides those previously stated, are that the patient experiences but little pain and inconvenience, and can, as a rule, attend to his business almost immediately after the splint is applied.

It is not necessary that all the teeth, nor, indeed, that any should be present in the mouth in order to make this splint serve its purpose. In the first case the rubber can be made to take the place of the missing teeth, and in the latter case a perfect adaptation of the splint to the alveolar ridges can be secured, and will be found to keep the parts in perfect apposition.

Should it be deemed advisable to place a splint in position within an hour or two after seeing the case, one can be constructed entirely of ordinary gutta-percha, with just enough wire inside to stiffen it. Dr. Carr demonstrated this last method; it is very simple, and can be made by any surgeon.

THE ACTION OF CERTAIN DRUGS ON THE CIRCULATION AND SECRETION OF THE KIDNEY.

DR. CHARLES D. F. PHILLIPS, of London, read a paper with the above title before the Section in Therapeutics.

This contained a number of very interesting experiments, made with Roy's onkometer, with caffeine, sparteine, strophanthine, digitalin, and ulexine.* He concluded that the flow of urine is not so much dependent on the blood-pressure as on the rate of flow of the blood in the renal vessels. With regard to this point it is necessary to remember that, although such drugs as strophanthine produce a great increase in the *force* of the cardiac beats, yet these are very much slowed, so that it is quite possible that, although the heart's action is stronger, yet the total amount of blood sent through any given organ, such as the kidney, in a given time, may remain the same; whereas such a drug as digitalis, producing,

as it does, a rise of blood-pressure and a contraction of the kidney-vessels, may cause an increased quantity of blood to pass through the renal vessels. On this view one could find the explanation of digitalin being a diuretic and strophanthine not being one.

Inasmuch, however, as sparteine has not so marked diuretic action, we must also assume that digitalin must have some peripheral action on the secretory apparatus of the kidney.

His results were tabulated briefly as follows:

(A) DRUGS THAT FIRST CONTRACT AND AFTERWARDS DILATE THE KIDNEY.

(1) *Caffeine* in small doses induces in the stage of contraction a fall of blood-pressure, in that of expansion a slight rise. During the former the flow of urine *may* be arrested; during the latter it is always increased, such increase depending on dilatation of renal vessels.

(The possible *arrest* of secretion during the first stage is special to caffeine, and may be induced by large or repeated doses.)

(2) *Ulexine*—gr. $\frac{1}{2}$ —greatly raises blood-pressure during the first stage (that of contraction); in the second, expansion is much greater in degree but shorter in duration than under caffeine, and is accompanied by brief but marked increase in urinary flow; the effective dose is limited by its toxic action on respiratory centres. Practically, *excess* of caffeine induces only the first stage, *excess* of ulexine only the second.

(B) SUBSTANCES THAT DILATE THE KIDNEY, BUT TO LESS EXTENT AND MORE SLOWLY THAN CAFFEINE AND ULEXINE,

are dextrose, urea, sodium chloride and acetate, and probably all constituents of the urine.

(C) DRUGS THAT CONTRACT THE KIDNEY WITHOUT SUBSEQUENT EXPANSION.

(1) Digitalin, with *increased* secretion of urine (probably resulting from general heightened blood-pressure).

(2) Sparteine, with *diminished* secretion (in health, at least).

(3) Strophanthine causes slight temporary contraction, with no marked increase of secretion.

(4) Apocynëine, similar to temporary contraction, and no definite increase of secretion.

(5) Turpentine, (6) adonidin, and (7) barium chloride give similar results.

In conclusion, it seemed to him that the

* This is an alkaloid from the gorse, *Ulex europæus*.

plethysmographic method of experimentation is a valuable one for determining the exact action of drugs on the circulation, and one that deserves more attention than it has hitherto attracted.

A NEW METHOD OF TREATING DISEASES OF THE SKIN LOCALLY.

In the Section in Dermatology and Syphilography DR. VALENTINE KNAGGS, of London, England, proposed as a substitute for ointments the employment of emulsions, which, upon drying on the skin, form protective films. He had employed these dressings for the past two years with gratifying results in eczemas and other non-specific exudations. The inunction of the body with fixed oils has been found of immense service, but they are not adhesive, and exuding fluids readily escape from the surface. There are two methods of rendering oily substances adhesive,—1. By adding to them resinous, gummy, or alkaline substances; 2. In making use of gums to combine or emulsify a fat with water.

Adhesive preparations, unlike oils, tend to arrest skin-action. Thus tar, varnish, or colodion form an impervious covering. Ointments to which adhesive substances are added diminish skin-action, but do not abolish it.

Well-made emulsions resemble milk or cream, are soluble in watery fluids, and are markedly adhesive, and are made by combining an ointment-basis with water, a vegetable gum, and a suitable antiseptic.

Thus the formula preferred would read :

- R Paraffine molle, \mathfrak{z} i;
 - Pulv. gum acac., gr. clx;
 - Boracic acid, gr. xvi;
 - Aquæ, ad \mathfrak{z} ii.
- Stir until emulsified.

Bismuth, zinc, sulphur, or other medicament may be added as desired. Smear over the skin, a film is formed, which is flexible and protective, and the antiseptics and medicaments have the best opportunity of exercising a beneficial influence.

The author called especial attention to the fact that all lint and textile dressings could be dispensed with. He did not expect these gum emulsions to displace older methods, but that they would serve a useful purpose.

In discussing the paper, DR. UNNA said that we were now in the period of transition, making our annual change of treatment. It was very well for us as specialists to discuss new treatments, but we should not give them to the general practitioner until we were quite sure that they were good, and especially should

not confuse him with new treatments until we were quite sure that they were new. He had worked much with fixed dressings and varnishes, and some years ago had described such a varnish as had the reader of the paper. He was glad to confirm the reader's claim regarding the utility of the emulsion-dressing, but could not concede to him that it was new, as there are many other varnishes made with gums and fats. He did not believe that any varnish which is soluble in water can prevent a great amount of evaporation from the skin.

A NEW METHOD OF TREATING THE VEGETABLE PARASITIC DISEASES OF THE SKIN.

DR. H. J. REYNOLDS, of Chicago, Ill., read a paper with the above title before the Section in Dermatology and Syphilography, of which the following is an abstract :

First, the parasiticide must be applied so as to reach the bottom of the hair-follicles in favus, ringworm of the scalp, and barber's itch. He proposed to apply the medicament to the diseased part and place over it the positive pole of an electric battery, and the negative upon some other part of the body, and induce the penetration of the solution to the deeper parts by a well-known law of electro-physics. He uses a battery composed of a large number of small cells, such as is used for the removal of hairs. The strength of the current must vary with the sensitiveness of the parts,—five to fifteen cells, according to the feelings of the patient. Where there is much hyperæmia the current must be weakened. Cocaine, applied in this way, produces anæsthesia of the whole scalp. The surface is first to be thoroughly cleansed. Then saturate the sponge of the positive electrode with the parasiticide solution and place over the diseased patch, and the moist negative sponge over the skin of some other part of the body. A one per cent. solution of the bichloride was the parasiticide employed in the cases reported. He had only had an opportunity to thus treat three cases, but all have been so successful as to give him great confidence in its usefulness.

RECENT VIEWS AS TO THE PATHOLOGY AND TREATMENT OF TUBERCULOSIS OF THE LARYNX.

MR. LENNOX BROWNE, of London, read a paper before the Section in Laryngology with the above title.

The tubercular bacilli are generally ad-

mitted as a cause of specific laryngitis. Entrance is effected through the air-passages, and they are especially liable to accumulate in the upper parts of the lungs, where there is less respiratory action. The disease is usually secondary to pulmonary tuberculosis, and may be due to infection from the bacilli in the sputa coughed up and inoculating some abraded or unhealthy and irritated portion of the larynx, or the germs may find their way thither through the lymphatic system. The bacilli, like all parasites, act as an irritant, and eventually cause breaking down of the tubercular deposits.

They must have an unhealthy or abraded surface on which to locate and thrive, and are prone to choose some weak point. Whether carried by the air, sputa, lymphatics, or general circulation, cases are recorded of infection through wounds and teeth that have been extracted. The author of the paper quoted cases confirming the same.

The state of the health and the assimilation of food, together with tissue-nutrition, have more to do with the development of tuberculosis than have locality or climatic conditions. Not only may we have laryngeal tuberculosis as a secondary infection, but we find cases where it is primary. The laryngeal symptoms may be the first to attract attention, and even become far advanced before pulmonary lesions can be detected. This is confirmed by many observers. The bacilli are recognized in the sputa, there is pain in the larynx, and difficult deglutition.

The larynx presents the specific appearance. We find the infiltration, swelling, and ulcers, but still can detect no pulmonary lesion. There must have been some neglected chronic laryngitis, or some solution of continuity when exposed to the presence of these germs. Cases are reported where these local symptoms have yielded to treatment before pulmonary complications were added, and the patients were discharged apparently cured.

Treatment.—Where the general system is not broken down, or the disease advanced to the lungs, sea- or mountain-air and high altitudes, especially in pine regions, are of vital importance. Oxygen, pure air, and the absence of germs are here more to be relied on than the thermal or climatic agents. Dr. Moore has ceased to advise the inhalation of medicated steam, but prefers oxidizing agents. Inhalations of vapor from turpentine, oil of eucalyptus, and menthol he has used with success.

It is well established that tuberculosis is a blood-poison, as are pyæmia, septicæmia, and the like. Germicides should be used, and benefit will result. He places great confidence in atropine, not only as a sedative, but as a germicide as well. Arsenic often works in the same manner as does mercury in syphilis. So, also, do the salts of calcium, where there are tubercular deposits. The aniline treatment has not been a success, and the gaseous injections are still on trial. Experiments with sulphuretted hydrogen show temporary improvement, with diminution of the amount of sputa expectorated, less pain, and less distress from persistent cough. Still, the permanent benefit is doubtful. This treatment needs careful supervision, and should not be trusted to the patients or their friends. The local treatment of tubercular laryngitis gives the best results, especially where systemic treatment is also employed to maintain health and nutrition. Use cocaine, and employ the galvano-cautery or lactic acid to destroy the deposits and induce healthy healing of the parts.

Where the infections are local, our success is in proportion to their accessibility.

He does not like iodoform or iodol dissolved in ether, as the ether is too much of an irritant, and prefers a brush made with cotton to the spray, in that it coats the surface better and is pressed into folds which are protected from the spray by the spasm of the larynx. The continued use of the spray he considers dangerous to the ciliæ of the epithelial cells. Local and systemic sedatives are emphatically called for. Insufflation is not as good as where emulsions are made with acacia, as it is apt to form cakes. Cocaine gives temporary relief, but morphine, belladonna, and balsam are more permanent in their relief of both pain and cough.

The surgical measures are to scrape away the deposits with curette or forceps, under cocaine, and apply lactic acid. Do not stab or incise; it may relieve tension and congestion, but is bad in that it gives new foci for infection. For the same reason it is better not to remove glomerulata unless respiration is seriously interfered with. Tracheotomy, for the purpose of giving rest to the larynx, is useless, and worse. The larynx does not then receive the necessary air and oxygen, and bacilli-infected mucus accumulates. The cold and dry air irritates the lungs and may induce pulmonary complications. Besides, the wound may become infected. Intubation of the larynx likewise causes too

much irritation and aggravates the trouble, independent of the risk of blocking up the tube. Even refrain from removing an elongated uvula. He does not approve of the recent suggestion of extirpating diseased portions.

Many apparent cures are reported, and he has had such cases himself, but is inclined to doubt their permanence. We can improve the condition of the larynx, stop pain and cough, cause better assimilation of food, and improve nutrition. There result local relief and apparently satisfactory results, but scarcely a cure, as claimed by Schmidt, Bosworth, and others.

Important Suggestions.—1. Early diagnosis and treatment. 2. Do not be carried away with new remedies. 3. Never be too active in destroying tissue; heal instead. 4. It is better to observe facts and be influenced by the experience of many, than by the new ideas of the few.

ON THE PHARMACOLOGY OF SOME BODIES DERIVED FROM MORPHINE.

DR. RALPH STOCKMAN, of Edinburgh, read a paper with the above title before the Section in Therapeutics.

The experiments were conducted jointly by D. B. Dott, F.R.S.E., and Ralph Stockman, M.D. The relationship between chemical constitution and physiological action must always be a subject of deep interest to pharmacologists. In this short paper they proposed to mention briefly the changes in action resulting from various modifications in the constitution of morphine.

How, in 1854, by acting on morphine with methyl iodide, obtained a body which he named hydriodate of ethylmorphia, and which he regarded as a substitution product, the methyl iodide being supposed by him to replace one of the hydrogen atoms in morphine. In the light of our present chemical knowledge How's body may be regarded as an addition product, iodide of methyl (CH_3I) being simply tacked on to the morphine molecule.

In 1869, Crum Brown and Fraser investigated this body among others, and showed that the original action of morphine is quite lost, and a curare action substituted in its stead. From their nomenclature there can be no doubt that these observers regarded such bodies as addition and not as substitution compounds. Notwithstanding this, the authors find that in all text-books and reference-books these substances are always named and described as if they were substitution and not

addition bodies. It is at present generally held that the substitution of methyl for hydrogen in an alkaloid causes the latter to act like curare, no matter what its original action may have been. The addition products, however, are very different in action from the substitution products.

The formula of morphine is $\text{C}_{17}\text{H}_{17}\text{NO}_3(\text{OH})_2$, and it contains, therefore, two molecules of hydroxyl. It is the hydroxyl-hydrogen atoms which are replaced most easily by alcohol radicals. With regard to the action of morphine it may be divided into two stages,—(1) narcosis, succeeded by (2) tetanus. Methylmorphine, $\text{C}_{17}\text{H}_{18}(\text{CH}_3)\text{NO}_3$, is morphine in which one H has been replaced by CH_3 . Codeine has the same constitution, and this body is simply codeine prepared artificially from morphine. The action is exactly the same as that of codeine derived directly from opium.

Ethylmorphine, $\text{C}_{17}\text{H}_{19}(\text{C}_2\text{H}_5)\text{NO}_3$, has the same action exactly as methylmorphine.

Acetylmorphine, $\text{C}_{17}\text{H}_{18}(\text{C}_2\text{H}_5\text{O})\text{NO}_3$, and diacetylmorphine, $\text{C}_{17}\text{H}_{16}(\text{C}_2\text{H}_5\text{O})_2\text{NO}_3$, have a similar action to the two preceding bodies. That is, they produce narcosis in very small doses, which is followed by tetanus when larger doses are given. All these bodies are much more active than morphine, and smaller doses are required. In dogs, however, they produce much greater distress and much more marked vomiting and diarrhoea. From examination of their action, the authors think that none of them is in a position to replace morphine clinically.

SO-CALLED ANTISEPTIC ACTION OF CALOMEL WHEN GIVEN IN LARGE DOSES.

DR. GEORGE S. HULL, of Chambersburg, Pa., read a paper with the above title before the Section in Therapeutics.

In cases of dysentery most prompt results in relieving tormina and changing the character of the stools were manifested. It acts as a cholagogue, producing a free flow of bile, sweeping out the contents of the bowel, and as a mercurial it exerts an antiseptic action. In cholera its usefulness in large doses has been advocated by some and denied by others.

In the discussion the relative value of large and small doses of calomel was freely considered by the members of the section.

In closing the discussion, Dr. Hull said that he was dealing with epidemic dysentery, and not with ordinary dysenteric conditions.

The first effect of the calomel is to empty the bile-ducts and get a large flow of bile, and relieve the congestion of the liver and intestinal vessels. The second effect is due to the solution of the mercurial in bile, as pointed out by Headland, and this probably acts as an antiseptic in the bowels. The object is not simply to purge the patient, but to obtain a copious bilious discharge from the action on the liver. Where the tongue was most coated he got the best results. He believed that patients are killed by the use of opium and astringents.

*NOTES ON THE TREATMENT OF PHTHISIS,
MORE PARTICULARLY THAT BY INTRA-
PULMONARY INJECTION.*

R. SINGLETON SMITH, M.D., London, F.R.C.P., Physician to the Bristol Royal Infirmary, England, read a paper on this subject before the Section in General Medicine on Thursday, September 8. Since the last International Congress at Copenhagen, in 1884, numerous attempts have been made to do more than had previously been attempted for a disease in which the *vis medicatrix naturæ* does so little. The reader of this paper briefly summed up the various methods which have been recently suggested since the discovery of the bacillus of tubercle, and expressed his belief in the possibility of benefit by treatment directed towards the destruction of the bacillary growth. He reported the result of his experience with regard to gaseous rectal injections, and said that in consequence of the absence of all indications of benefit he had given up this method entirely. He alluded to the work done by Professor Pepper, of Philadelphia, and Drs. Beverley Robinson and White, of New York. In carrying out the method of intra-pulmonary injections suggested by these and other workers he had met with partial success in a series of cases reported in the *British Medical Journal* of 1886.

In consequence of the proved utility of iodoform in chest-disease, as shown by a steadily-increasing mass of evidence since its first introduction for this purpose by Professor Semmola, in 1878, and supported by a series of cases presented to the International Congress of 1884, in which the author found increase of weight, improved appetite, diminution of temperature, and general improvement, under the administration of iodoform given by the alimentary canal, it was thought that

iodoform would be the best substance to employ for injection into the parenchyma of the lung. The clinical utility of iodoform being the ground on which its use for this purpose has been founded, the evidence is not shaken by any statistics as to the comparatively feeble powers of the drug as a germicide.

The insolubility of the drug is the chief difficulty; various solvents have been used, but with only partial success. Ether is objectionable because of its effects on the brain; giddiness and other feelings of discomfort rather alarm the patient, and give rise to an unwillingness to have a frequent repetition of the injections. Eucalyptus oil is irritating: two cases were mentioned in which acute pleuritis, with much pain, rise of temperature, and effusion had followed the injection of an iodoform solution in oil of eucalyptus. The vaseline oil, either alone or in combination with eucalyptol, had also been used, but the author still considers the question what is the best fluid to inject to be still unsolved. He did not advocate the use of solutions containing free iodine or bichloride of mercury, and he would not in future employ any fluid for injection into the lung which had not previously been tested hypodermically; if it gave rise to much inflammatory irritation in the subcutaneous cellular tissue, he would not venture to inject it into the lung. He was of opinion that injections into cellular tissue might possibly be of some little service, although there was as yet not much reliable evidence on this point, but they would serve as a reliable test whether any given fluid was suitable for deep intra-pulmonary injection.

It is true that if iodoform be of use, as the clinical evidence indicates, then it is likely to be of far greater utility when injected, even in small quantity, into the focus of a diseased patch than when given in larger doses diffused throughout the whole body. Such injections have been shown to be not especially hazardous. Even the cases in which pleuritis has occurred had recovered completely from the attack in the course of a few days, and possibly the pleuritis was due to the failure of the fluid to pass beyond the pleural cavity into the lung-substance. Nevertheless, the author would not advocate the use of such injections in cases which were hopeless, neither would he employ them in cases where other and less active measures were accomplishing the object in view. He concluded his paper by urging perseverance in spite of failure, and by expressing his belief that what

as yet was only a tentative investigation would ultimately result in numerous and signal successes.

DEVENTER'S METHOD OF DELIVERY OF THE AFTER-COMING HEAD.

DR. JOHN BARTLETT, of Chicago, Ill., presented a paper with the above title before the Section in Obstetrics, supplementing the paper with a demonstration upon the phantom.

Deventer spoke in the most confident manner of the success and safety of podalic version, and of the ease with which the head could be delivered, but did not describe his method, which, however, Dr. Bartlett had found mentioned in Smellie's work. Deventer's method was shown to consist of a reversal of the so-called Prague method, in that the body of the child was carried far backward towards the perineum, with the view of turning the occiput out from under the pubes, the anterior surface of the neck resting on the perineum. At the beginning the occiput of the child was turned forward so as to come under the pubes as the child was drawn down. The arms were *not* to be drawn down, but left up alongside the head, being placed so as to come anterior to either parietal base. The delivery by traction backward upon the body was to be aided by pressure made immediately above the pubes, the wedge formed by the head and arms being decomposed by the withdrawal of the larger transverse diameter of the head from between the arms, as descent of the head accompanied by extension occurs. The mechanism was only favorable when the occiput was anterior. Deventer never lost a child or tore a mother. The arms, being left up, protected the neck of the child and allowed a passage for the cord alongside of them, so that haste was not as necessary as with ordinary methods, and, occupying a broad and yielding part of the pelvis, they did not obstruct delivery. The method was a plausible one, and certainly worthy of trial in suitable cases.

THE CURABILITY OF DETACHMENT OF THE RETINA.

PROF. X. GALEZOWSKI, of Paris, France, opened the session of the Section in Ophthalmology on Thursday, September 8, by reading a paper with the above title. He stated that the pathology of the disease is not entirely clear.

The writer had observed in twenty years,

among 152,000 persons, 789 detachments, of which 87 were in both eyes, 63 in emmetropic and hypermetropic eyes, and 194 were traumatic; 13 occurred after extraction of cataract, 18 were syphilitic, and 4 in sympathetic affections. Tumor was found in 10 cases. Twice only he found detachment in retinitis albuminurica, although he frequently saw this affection. Cataract is very frequent in detachment of the retina.

Occasionally tearing of the retina is noticed, with the corpus vitreum introduced behind the retina, between the choroid and retina. He could say that the rupture of the retina is not so frequent, and considers it the consequence and not the cause of the detachment. Professor Graefe has said that the detachment is not curable, and the function of the retina is not restored. Dr. Galezowski had seen a case which showed alterations in the retina at the place of detachment, which had been completely cured. The patient gave the usual history of trouble with the vision, coming on suddenly and continuing for one or two or three months, with afterwards recovery of sight. He explained the appearance of the fundus as seen by the ophthalmoscope, and illustrated them on the blackboard.

The conditions predisposing to detachment were said to be (1) choroiditis; (2) liquefaction of the corpus vitreum. In treating these cases he begins with antiphlogistic treatment, atropia, rest, etc., and he had in seven cases a complete cure,—the retina completely adherent, and around the line of the separation atrophy, with pigment-deposit and choroiditis disseminata. The first indication is antiphlogistics. Apply every month two, three, four, or five leeches, then atropine, and warm and cold compresses alternately, and in the intervals between the leeches he applies derivative plasters. Inside of five months he has completely cured detachment of the retina. Mercury and potassium iodide are also useful where exudation is present, or in cases of constitutional disease.

Fifteen years ago he proposed iridectomy to stop the inflammation of the choroid, but it did no good in that way, although it stopped the iritis. Now he proposes a new operation. He considers the exudation behind the retina as being of the same character as the effusion in pleuritis or peritonitis, and has had an instrument (which he exhibited) made to aspirate the fluid. The instrument is a syringe with a stop-cock and an aspirating-needle. He introduces the needle through the sclerotic at a considerable distance be-

hind the ciliary body, and passes it into the globe for some distance. Then he exhausts the air by drawing out the piston. If the needle-point is too far in, no fluid appears in the barrel of the syringe, but on withdrawing the needle gradually the fluid appears, and one, one and a half, and two grammes are generally obtained. There is no inflammation after the operation. By this means two out of seventeen cases operated on were completely cured, and there is a certainty of amelioration in all cases.

In old cases he introduces a curved needle from behind forward through the sclera and the detached retina, before introducing the aspirating-needle, and when the fluid is drawn off a catgut ligature is drawn through as a seton and brought tight.

SEBORRHŒAL ECZEMA.

DR. P. G. UNNA, of Hamburg, Germany, read a paper (with microscopic demonstration) on "Seborrhœal Eczema" before the Section in Dermatology and Syphilography. The author does not consider that the diagnosis "acute" or "chronic" eczema is a sufficiently exact and scientific one. For example, there are three distinct types of infantile eczema of the face, viz., a nervous, a tuberculous, and a seborrhœal. The nervous type is seen in the eczema of dentition, appearing upon a perfectly sound skin, usually first upon the cheeks and then upon the forehead. The eruption itches in proportion to the strength of the infant and the thickness of the epidermis. The vesicles, at times, suggest in their appearance and their reddened base herpes zoster, but the marked symmetry of the lesions and the tendency to relapse would prevent such a diagnosis. Seborrhœal eczema is entirely different, in that the skin is not in a previously healthy condition. A seborrhœa has existed upon the scalp probably a few weeks after birth, which often spreads over the upper portion of the face after becoming somewhat moist. There is less itching than in the eczema of dentition. For the latter affection a zinc-ichthyol ointment is recommended to be applied and covered with a mask, together with the bromide of potassium, internally, to allay nerve-irritation. In seborrhœal eczema sulphur should be added to the zinc ointment. Ichthyol is useless, but resorcin acts well.

Dr. Unna regards all so-called dry seborrhœas as chronic inflammatory processes of the skin, and his studies convince him that

there is no hypersecretion from the sebaceous glands which can clinically be considered a dry seborrhœa, produced by a deposit upon the surface of the product of these sebaceous glands. The disease which Unna has named *eczema seborrhoicum* is dependent upon a condition of, or rather change in, the coiled or sweat-glands, giving rise to the secretion of fat by them. An increase of fat upon the surface indicates increased activity when it proceeds from the sebaceous glands, but when the sweat-glands pour out fat it is because of the death of their endothelial cells.

Almost all seborrhœal eczemas have their starting-point in the scalp. Three forms are described. In one, *eczema seborrhoicum* begins as a latent catarrh of the scalp, and goes through the stages of scaly formation and dryness, finally ending as a hyperidrosis oleosa. In the second, the scales heap themselves up between the hairs into fatty crusts, and cause the hairs to fall out. A corona seborrhoica upon the forehead, at the margin of the hair, is described, which is typical of this form of the affection.

The third form is that in which the catarrhal appearances are the most pronounced, and in which "weeping" occurs, especially about the temples and eyes. This follows a simple itching pityriasis, and produces the appearances of a moist, shining eczema. A pityriasis or a seborrhœa may exist upon the scalp, while at the same time an eczema is present upon the face. The chest is affected with the crusty form almost exclusively.

Upon the arms there is a predilection for the flexor surfaces, which is explained by the rôle the sweat-glands play in *eczema seborrhoicum*.

Upon the legs, early in the disease, we find only the large papular and crusting forms.

Patches of seborrhœa about the mouth and nose of old people are often the starting-points of carcinoma. In almost all cases of *eczema seborrhoicum* of the scalp, a simple, itchy scaliness of the ear is observed. A patch of *eczema seborrhoicum* is extremely stationary, remaining for years possibly without much change in size and giving rise to only slight symptoms. Beginning upon the scalp or head, as a rule, it extends to other parts below in a very gradual manner, especially locating upon the face, sternal and intra-scapular regions. This course is so the rule as to be regarded as pathognomonic, as no other eczema or psoriasis runs this course.

When the whole body becomes involved it

resembles closely pityriasis rubra. Psoriasis is often confounded with seborrhœal eczema. The latter attacks the parts near the median line of the body, and is more stationary than psoriasis. It is preceded by a local seborrhœa, and the scales and crusts have a decidedly fatty character. The patches have also a peculiar configuration, and spontaneously flatten out in the middle or upon one side. The prognosis is more favorable than in psoriasis. The cure is not easy because the deep-seated sweat-glands are implicated. Sulphur is the great remedy for the disease. More active remedies for the scaly and crusty forms are pyrogallol and resorcin. Internal treatment is seldom required. Once cured, prophylactic measures, such as hygiene of the skin, must be employed.

IODOL IN SURGERY.

DR. GEORGE ASSAKY, of Bucharest, Roumania, read a paper on "Iodol in Surgery" before the Section in Surgery on Friday, September 9. The conclusions arrived at were: (1) Wounds unite under iodol by first intention. This union, however, being the result of various and complex conditions attending operation, it is not possible to attribute to iodol alone the absence of suppuration and inflammatory conditions. In wounds which gape and suppurate, iodol is an excellent antiseptic. It rapidly retards suppuration, renders it odorless, reduces the frequency of dressing, and hastens considerably cicatrization. In ulcerating or gangrenous wounds iodol aids to resist the destructive process, and changes the wound, after a variable time, to a healthy, granulating condition. This action of iodol extends itself to hard chancres. In case of soft chancres the result is variable. Sometimes it transforms them into a simple wound with brief delay; at others it is insufficient for this purpose, and it becomes necessary to employ in addition, locally, antiseptic lotions.

The same is true with reference to open venereal buboes of the groin. The powdered iodol has this advantage over iodoform, that it is free from odor and is not toxic in its effects.

(2) Doses of iodol of from 0.40 centigramme to 2.0 grammes daily produce no functional trouble, even if continued a long time.

These doses give marvellous results in tertiary syphilis and in scrofulous affections. In the secondary stage of syphilis, taken inter-

nally, it rapidly destroys the syphilitic manifestations. Iodol seems to aid the general nutrition and increase strength and flesh. It is indicated in all cases of specific malnutrition.

Iodol is an antipyretic. In acute infectious diseases, such as erysipelas, etc., it causes a rapid fall of temperature.

THE TREATMENT OF ABSCESES AND ULCERATIONS OF THE CORNEA WITH JEQUIRITY.

DR. E. SMITH, of Detroit, Mich., read a paper with the above title before the Section in Ophthalmology on September 9. He remarked upon the experience, common to all, of the difficulty in procuring the absorption of pus in the cornea, and noted the existence of the same tendency in all closed abscesses. The best means of arresting suppuration and of getting rid of the pus when formed has engaged the attention of the writer, with many others, for years. A paper on the above subject, in the spring of 1883, with another published in October, 1883, gave the result of his observations up to that time. He had since had many cases of ulceration of the cornea speedily relieved, and an astonishing clearing up of the cornea, after its use. He believes the remedy affects the proliferation in corneal corpuscles. After explaining his impression of the mode of action of the remedy, he proceeded to describe his manner of using it. He does not use a strong preparation, and aims not to produce a sharp inflammation, as is done in trachoma. He uses a three per cent. solution, or a very minute quantity of the powdered seed. It is applied sparingly, till a mild catarrhal inflammation is set up, characteristic of the remedy, and in some cases there may be slight membrane. The object is to avoid a high degree of reaction. The eye is kept washed out with a two per cent. solution of boric acid, and the result is almost uniformly surprisingly good. The corneal cicatrix is often hardly apparent to any one but the patient.

DR. GALEZOWSKI, of Paris, France, did not like jequirity. In his observation it had frequently produced ulceration and destruction of the cornea and synechia anterior, and in some cases enucleation had to be made to avoid sympathetic trouble. He thought jequirity exerted a very bad action on the cornea. The modification in Dr. Smith's method is doubtless in the amount of the

drug used. Dr. Galezowski thought it a dangerous method.

In intermittent fever he had found ulceration of the cornea, which yielded to the administration of quinine. In another case, lasting for several months, after the extraction of a tooth, cicatrization occurred. The best treatment for corneal abscess and ulcer is the antiseptic method. He applies the powdered iodoform directly to the surface three times a day, under cocaine, and uses the steam douche two or three times a day, ten minutes at a time. When it is not doing well cauterization with a solution of nitrate of silver, 25 centigrammes to 10 grammes, may be done one or two times every day.

DR. RICHEV, of Washington, D. C., wished to know whether scraping the ulcer before applying the remedy had not been found of advantage.

DR. SMITH, in closing, said that Dr. Galezowski had used jequirity in trachoma, in the way described by De Wecker, till he obtained marked diphtheritic membrane. In these cases it was the swelling and chemosis that caused strangulation and loss of cornea. He should hesitate to use jequirity in sthenic cases; it was the asthenic cases requiring stimulation that were suitable for this treatment.

THE CHEMISTRY AND PHARMACOLOGY OF THE NITRITES AND OF NITRO-GLYCERIN.

A paper with the above title, by GEORGE ARMSTRONG ATKINSON, M.B.C.M., was presented, and in the absence of the author was read by DR. RALPH STOCKMAN, of Edinburgh, before the Section in Therapeutics on Thursday, September 8, fourth day.

The action of the salts of nitrous acid resembles closely those of the acid which is the essential basis of this group of medicinal agents. Nitrous acid is remarkably unstable; in watery solution of $\frac{1}{100}$ it may be used for a day or two for experimentation, but it has no advantage over a solution of nitrite of sodium, which possesses identical effects in so far as an acid can be considered identical with one of its salts. Our knowledge of the action of the nitrite group has been chiefly derived from a study of the effects produced by nitrite of amyl. Since here the base (amyl) has a decided action of its own, it is necessary to select a salt in which the base in its combination possesses no well-marked physiological activity. The resemblance between the action of sodium nitrite and amyl nitrite has

been pointed out by Gamgee, Lauder Brunton, Hay, Leech, and others. Barth described its highly poisonous qualities. Binz showed that it caused death from general paralysis, especially of the muscular system, no convulsions preceding the fatal issue. Reichert considered it identical in its toxic effects with potassium nitrite. Its effects may be summed up as a paralyzer of muscular tissue, non-striated muscle being affected less quickly than striated. The brain-centres are also affected. The blood becomes of a chocolate color in mammals (methæmoglobin), respirations are slowed, temperature slightly lowered. Death occurs in frogs from cessation of respiration; after the heart has stopped its movements, it is found in full diastole and quite inexcitable.

Post-mortem rigidity comes on early. In rabbits, 3 grains were a fatal dose in one three pounds in weight. The same appearances were found post-mortem. In man, small doses (8 grains) produced great tendency to faintness and considerable acceleration of pulse, and decided lowering of arterial tension. Paralysis of respiration is due to the effect of the nitrite on the muscular system chiefly, but also in part to the effect on the medullary centre. Small doses slightly increase the flow of urine; large always diminish it. Urea and uric acid are almost unaffected. Sugar appears in the urine of rabbits after some hours, if the animal be kept very decidedly under the influence of the drug, but rapidly disappears if the administration of the drug be stopped. The nitrite is largely destroyed in the system, being partly, however, excreted as nitrate, partly, probably, as urea; a portion of it is excreted as nitrite.

The pharmacology of the other nitrite is briefly dismissed. Nitrite of potassium, nitrite of ethyl, nitrite of amyl, act in very similar manner to the sodium salt. Nitro-glycerin acts partly as a nitrite, and partly *per se*. In small doses it exerts the nitrite effect as a paralyzer; in large doses it produces convulsions.

DR. MURRELL, of London, England, referred to his discovery of the usefulness of nitrite of amyl in the condition of angina pectoris, and he always advised patients to carry the medicine in a small bottle. The pearls he considered too expensive for use. The taballæ (Ch. B.) of nitro-glycerin, made with chocolate, he considered dangerous from their resemblance to confections. He has used nitro-glycerin in one per cent. solution (dose mg v-xv) in cases of neuralgia of the

fifth nerve, surgical shock, asthma (spasmodic and cardiac), and reflex neuroses. He preferred this in epilepsy to the nitrite of sodium, which had been recommended by Dr. Law. In angina, patients can take 15 minims when they feel the attack coming on; such patients should carry a small bottle with them for immediate use when they feel the attack coming on, otherwise they might perish before the agent could be obtained. He gave an amusing instance of the difficulty of obtaining nitro-glycerin in England at present.

ON THE MAXIMAL DOSES OF DRUGS.

DR. L. LEWIN, of Berlin, read a paper with the above title before the Section in Therapeutics.

Of the many difficulties which pharmacotherapy has to strive against, the dosage of medicine is by no means the least. Variation in dose arises (1) from the differences (a) between one person and another; (b) between single individuals at different times; (c) between the intensity of the disease in men suffering with the same affection; (d) between diseases in which the same drug is used. (2) From the variability in the activity of the greater part of our remedies.

At the same time it is possible and desirable to establish the usual dose of agents which are active in relatively small quantity, and which readily produce toxic effects when the dose is increased. Two groups of preparations fall under this head: (1) Plants (crude) and plant-products, and their pharmaceutical representatives; and (2) chemical substances such as metalloids, metallic salts, and carbon-compounds.

The first group is almost universally inconstant in its effects, and thus far an international agreement as to their maximal doses has not been possible. The remedies of the second group, on the contrary, are nearly uniform, and the doses beyond which they cannot be given without danger can be determined by physiological experiment; but although the basis for such agreement is tolerably broad, yet the statements given in different pharmacopœias in many cases vary greatly. Such variation can be easily explained in the case of the first group, but becomes incomprehensible in the second.

From the results of his own observation and a comparison of the most of the pharmacopœias which give maximal doses, the author had constructed a table of the ordinary

maximal doses of many of the drugs belonging to the second group, which he appended to this communication. Such a list should be added to the pharmacopœias of such countries as have no maximal dosage, for the convenience of the practitioner, who thus would be enabled to prescribe such drugs with confidence, even if they should not be generally used in his own country. From this Congress he hoped the influence would go out which would make such an international agreement possible.

RESORCIN AND ITS PREPARATIONS.

DR. JUSTUS ANDEER, of Munich, read a paper with the above title before the Section in Therapeutics. In this paper the author briefly gave the result of ten years' experience with pure resorcin. He had found it non-toxic, antiseptic, and possessing many advantages over carbolic acid, being free from odor and non-corrosive to the skin. He had obtained excellent results from it in eczema, in keloid, and in parasitic skin-diseases, as well as diseases of mucous membranes. In the form of keratine-coated pills it can be given for bronchitis, or in combination with castor oil (one to two per cent.) for diarrhœa and dysentery. For local use it may be combined with cacao-butter as a salve, or it may be made up into a soap of varying strength, from one per cent. up. Failure to obtain satisfactory results from its use may arise from not using a chemically pure resorcin, or from giving it in insufficient doses.

DR. LEWIN said that all are familiar with the writings of the lecturer upon the subject of resorcin. He thought that by devoting exclusive attention to this one member of a group the others might be in danger of having their value slighted. What is the value of thymol? What does resorcin accomplish more than phenol, carbolic acid, and others of this class? He questioned the statement that resorcin is not toxic, since it can, in large doses, present a condition of cerebral confusion and excitement which closely resembles mania.

DR. ANDEER replied that the agent was an efficient antiseptic, tasteless, odorless, and, in ordinary doses, free from toxic effects. He considered it a valuable addition to our therapeutic resources, and superior to phenol and thymol in many respects.

Correspondence.

PARIS.

(From our Special Correspondent.)

With the month of August the *season of vacation* has begun. The schools of medicine and of pharmacy have closed, and the professors have left the city, together with the four thousand medical students and the nine hundred pharmaceutical, or most of them. The library of the faculty closed its doors on the 1st, that of the College of Pharmacy on the 15th, and all the medical and pharmaceutical societies, as well as most of the scientific, have adjourned their meetings till October. The Academy of Sciences alone, faithful to time-honored precedents, continue their weekly sittings, but with so limited an attendance this year that they intend next summer to take some vacation, like the rest of the scientific world. And yet lately they had the visit of Dom Pedro, the emperor of Brazil, no doubt so well remembered by Americans, who, as one of the eight foreign corresponding members of the academy, attended several of the meetings, and took a share in the discussions.

But it is an ill wind that blows nobody good. While the physiologists, biologists, and toxicologists, both medical and pharmaceutical, are thus depriving Paris of their presence, the unfortunate dogs, cats, and guinea-pigs enjoy some rest from the experiments which they share in so interested a fashion. *Vivisection* and toxicology are no doubt useful and even fascinating studies, yet it cannot be denied that much unnecessary and wanton cruelty is practised under the cloak of scientific investigation. True, there is here a powerful society for the protection of animals, and also, it seems, an *antivivisection society*, aided by its British homonyme; but their first united effort, made the other day in a most injudicious manner, was a failure. After advertising a public meeting with bills partly in French and partly in English, they chose for a lecturer Madame Marie Huot, the same who hissed at the unveiling of Claude Bernard's statue, interrupted a medical lecture by striking the professor on the head with her umbrella, disturbed a pro-Pasteur meeting with constant interpolations, and in general made herself obnoxious by sensational vagaries. The meeting has been disastrous to the antivivisectionist cause, Mme. Huot having boasted of being a freethinker and a socialist, and wildly attacked nearly every

prominent scientific man. Continual uproar and disorder prevailed throughout, and the real aim of the meeting was lost sight of, the lecturer's own supporters being disgusted with her absurdities. And yet the antivivisectionists have some ground for their complaint. No one thinks of prohibiting vivisection, but some sort of regulation is not quite unnecessary.

If dogs and cats and the higher animals appeal to our feelings of mercy, the insects as a class generally find but little sympathy. Who has any love for the house-fly, for instance? It is by all conceded to be a plague and a nuisance. But scientists have more serious accusations to bring against it, for the house-fly is known to often be the means of spreading some contagious diseases. And now another charge is added to the list. Drs. Spillmann and Haushalter are of opinion that *flies spread the bacillus tuberculosis*. In a memoir read before the Academy of Sciences they have described experiments made with some of the flies that hover so pertinaciously around the spittoons of tuberculous patients. They have found living Koch's bacilli in both the abdomens of the flies and their excrements, and have no doubt, considering the persistent vitality of the bacillus, that such flies may become active vehicles of the contagion, near and far. As a prevention, they recommend that the spittoons be provided with close covers, and be cleaned with boiling water or a five per cent. solution of carbolic acid.

Some time since allusion was made to the project of coating with sheet lead the inside of the Arcueil aqueduct, which supplies Paris with its purest water—comparatively. The well-known sensitiveness of the public to any possible *lead contamination of drinking-water* stirred up considerable opposition, although chemists had declared beforehand that, considering the composition of the water, no danger could be apprehended. As the metallic lining was absolutely necessary, the work was done; but, to settle the question, a commission, composed of MM. Proust, Gautier, and Schutzenberger, was directed to analyze the water, and report upon its quality after its flow through a mile or so of sheet lead. Without entering into unnecessary chemical details, it may be of some interest to know how the operation was performed. One month was allowed to elapse after the completion of the lining to let things take their natural course. Then the commission collected fifty litres of the water above the

conduit and fifty litres immediately below, and both specimens were treated separately in precisely the same manner. The water, on being evaporated to two litres, let down a precipitate of carbonate of lime, which was separated by decantation; the clear liquid upon further evaporation to half a litre afforded a sediment of sulphate of lime, which was filtered out and preserved. A stream of hydrogen sulphide was now run through the clear liquor, slightly acidulated with acetic acid, and both specimens remained free from colored precipitate or even the faintest brown coloration. The sediments were next examined. On being macerated with dilute acetic acid, a portion was dissolved and a portion remained insoluble. The soluble portion gave for both specimens negative results with hydrogen sulphide. Finally, the insoluble portion, consisting mainly of sulphate of lime, was macerated for twelve hours with a solution of ammonium tartrate, in which sulphate of lead is soluble. Hydrogen sulphide proved that the liquor was equally free from metallic contamination. In consequence the commission, on reporting to the municipal council, gave it as their conclusion that the water of the river Vanne is, so far as lead is concerned, unaffected by its flowing through the Arcueil aqueduct. All chemists knew as much before the analysis was made, but nothing else than so thorough an examination would have satisfied public feeling.

While chemicals are under consideration, it may be well to end with the notice of an interesting discovery about *insoluble salts*, related by MM. W. Spring and G. de Boeck at the last meeting of the Paris Chemical Society. For theoretical reasons they think solubility and insolubility are only relative terms, and depend on several outward causes, hitherto not well understood. However it may be, they have succeeded in preparing *cuprous sulphide soluble* in plain water, and stable enough to bear ebullition and filtration. As the fact is of concern to chemists only, suffice it to say that the sulphide is rendered soluble by prolonged washing, intended to remove the slightest traces of all foreign salts. But another compound interesting to therapeutists is *brown oxide of manganese*, which can also be rendered *soluble* in water by what they call washing *à l'outrance*. The operation is simple enough. MM. Spring and De Boeck prepare brown oxide of manganese by reducing permanganate of potassium with hyposulphite of sodium, and persistently wash the brown pre-

cipitate by decantation with distilled water until the oxide redissolves, a fact rendered sensible by the deep brown color of the liquors. The solution thus obtained keeps well for a reasonable time, but is immediately decomposed by filtering, or upon the slightest addition of almost any salt. At the same time, although somewhat different chemically from ordinary brown oxide of manganese, the solution consists of nothing but oxygen and manganese, and may, therefore, find useful applications in therapeutics. It differs thus chemically from the preparation known as dialyzed iron, which necessarily contains a minute proportion of chlorine.

PARIS, August 23, 1887.

PLACENTA PRÆVIA.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—I wish to report a case of placenta prævia that recently came under my care, and also wish to invite whatever criticism any of the readers of the GAZETTE may choose to make in regard to the management of the same, for criticism given in the right spirit is next to advice, and often more valuable to the young practitioner.

The history of the case is as follows:

Mrs. J., aged 38, mother of five children. Was first called to see her June 1, 1887, at 1.30 P.M. She was awakened out of a sound sleep by quite a profuse hemorrhage. I found her very nervous and excited over the occurrence, as she said nothing of the kind had ever happened to her before, and she did not know but she was going to have a miscarriage. The hemorrhage soon ceased, and upon assuring her that I thought that was not the case she became more calm. Upon questioning her, I found that she was somewhere between five and seven months in pregnancy, but could not tell the exact time. Upon examination I found the cervix long and soft, and the finger could easily be passed to the os internum. As this hemorrhage had occurred without any ostensible cause and without warning, I looked at it rather suspiciously. I said nothing though in regard to what I thought, but gave her some advice in regard to future exercise, etc., and left her. On July 15 again, at midnight, I was called to her bedside. Another hemorrhage had occurred in precisely the same manner as before, awakening her out of a sound sleep. This time the hemorrhage was very much greater than before, but not to any alarming extent, as it

ceased spontaneously soon after my arrival. Upon digital exploration I found the vaginal fornix soft and boggy, the cervix long, wide, and soft. There was no doubt in my own mind as to the diagnosis. I frankly told her what I thought the cause of the hemorrhage was, and that rest and quietness on her part was absolutely necessary if she expected to go her full time. On the 17th I was again hastily summoned to see her. She was walking about in the garden when the hemorrhage began. This time it was, indeed, alarming, for she must have lost several pounds of blood by the appearances. On the 18th a consultation was called, and my diagnosis confirmed. The placenta was thought to be nearly central. As Mrs. J. was a strong, healthy woman, my colleague thought by keeping her quiet she might go her full time, as he believed it must be nearly up. The child seemed quite vigorous, and it was decided to let nature take its course for a few days longer, at least, in hopes of saving it if possible. This time the hemorrhage did not cease entirely as before. Notwithstanding she kept her bed for the most of the time, there was a continued oozing and dribbling, especially when she attempted to stand on her feet. At midnight on July 24 I was again called. The hemorrhage had again taken a fresh start. Further delay was useless if the mother's life was to be taken into consideration, and I determined to act at once. As the external os was only dilated to about the size of a quarter of a dollar, I resorted to tamponing. This checked the hemorrhage for the time being and started up the pains. In about four hours I removed the tampon, found the cervix dilated to the extent that two fingers could easily be introduced. I detached the placenta as far as I could reach and ruptured the membranes, and by some external manipulation I brought down the head, this acting as a plug, and as soon as it became fastened in the pelvis the hemorrhage practically ceased. The second stage of labor lasted about an hour. As soon as the child was born the hemorrhage became fearful, and upon examination, to my astonishment, I found another child was there. I immediately introduced my hand into the uterus, ruptured the membrane. The child was lying in the transverse position. I grasped the feet, and brought the trunk down into the pelvis. A few sharp pains and the second child was born. The placenta was removed and the hemorrhage ceased. All antiseptic precautions were used during labor and also afterwards, and my pa-

tient made a good recovery. Both children were still-born, and I think by appearances the mother could not have been more than seven and one-half months in pregnancy. I have given a full detail of this case for two reasons,—first, because placenta prævia, and especially with twins, is not a common occurrence; and second, because I never saw the full details of the management of a case in print.

In looking up authorities on placenta prævia I find such men as Thomas, Hoffmann, Barnes, Taylor, Spiegelberg, and others recommend the induction of premature labor as soon as the diagnosis is established.

Ought premature labor to have been introduced in this case as soon as the diagnosis was established, or was the expectant method better until the time came when it was absolutely necessary to act to save the life of the mother? In this case we were in the dark as to the mother's exact time, and also to the fact of there being twins.

Yours respectfully,

F. T. FIELD, M.D.

ELROY, WIS.

GELSEMIUM IN SUN- OR HEAT-STROKE.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—I was called early in July, 1878, one day about sundown, to see a young man, aged 25 years, stricken with heat- or sunstroke; found a crowd of both sexes outside gazing through doors and windows at the sufferer inside, who was bereft of sense and tossing in violent convulsions on the floor; arms and legs like levers governed by steel springs, were flying out, knocking chairs, etc., in all directions, his body rolling and tumbling on the floor.

I directed five men to rush in, seize, and hold him on his back, one man to restrain each limb, and the fifth to hold his body down. Being unsafe to introduce a hypodermic needle into arm, I threw twenty minims F. E. gelsemium into the cellular tissue over the pectoral muscle, and then relieved him of restraint; his violence gradually subsided, and he regained consciousness within half an hour, and one hour afterwards was able to swallow hydr. submur., gr. x, pulv. ipecac., gr. xx, bicarb. soda, gr. x. I then left him, feeling safe as to the result of the emetico-cathartic. The next day's visit found patient completely recovered. No subsequent treatment required. This case might have been serious but for prompt relief. After working hard all

day Saturday he ran over town in the afternoon to lay in supplies for Sunday, hence the overheat.

The wonderful and unmistakably good effects of the gelsemium in this case, and to my observation the close alliance existing, so far as cerebral congestion obtains, in the pathological conditions of the subjects resulting from sunstroke and from opium-poisoning, induced me to adopt this remedy in the treatment of the case of opium-narcosis reported in the June number of the THERAPEUTIC GAZETTE.

In heat-stroke, however, we may surely expect to find the liver greatly engorged and perfectly torpid, hence the indication for an active cholagogue, the effects of which may be enhanced by combination with ipecac and soda. The ipecac not only relieves the stomach—which may reasonably be considered in a state of atony—of undigested and hurtful substances, but has very calmative and soothing subsequent effects.

Gelsemium may have marked effect on the motor tract of spinal cord, paralyze respiratory nerves, cause certain inferior animals to move backward, and produce death in one-drachm doses, but notwithstanding, when properly administered in *suitable doses proper to the occasion* I have found it invariably an equalizer of the circulatory system and a preventive to local and congestive tendencies. From the stand-point of my personal observation of its physiological effects I would consider it an excellent adjuvant in the early treatment of cerebro-spinal meningitis. In cases of sunstroke there is more than a probability that many perish from neglect or failure to use the lancet freely when indications are most obvious to all but the prejudiced. The pulse should always be the indicator for its use. When the subject of heat-stroke is insensible, or in convulsions, with contracted pupils, flushed face, strong, bounding, or even full pulse, he presents certainly every indication for venesection, and should be bled for effect, and to effect let blood flow until the black begins to turn to red, even though twenty ounces be required. The lancet does not prevent resort to other appropriate measures, such as sponging body, cold to head, hot to feet, etc.; finally, when danger is overcome, by remedies. Stimulants have not been noticed because indications should govern their use. The secretions must not be overlooked, because this is a vital point in restoration.

On the other hand, a cool surface, very

feeble or intermittent pulse, pallor, preclude use of lancet, but not gelsemium. In all cases early and prompt treatment is imperative.

W. D. HUTCHINGS, M.D.

MADISON, IND.

WAS IT ANTIFEBRIN?

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—Early Sunday morning, August 14, was called to see a lady suffering with tonsillitis. She was feverish and restless, having slept but little the night previous. Ordered antifebrin in 5-grain doses every four hours. Saw her again in the evening, presenting a cyanosed appearance, lips and fingernails being a dark blue, and numerous bluish spots about the face and neck; pulse 112 and feeble. She had taken three doses,—in all fifteen grains. I discontinued the antifebrin and gave whiskey and digitalis, and the symptoms all disappeared in a few hours.

H. J. WINNETT.

LINCOLN, NEB., August 29, 1887.

"A NEW REMEDY FOR NIGHT-SWEATS."

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In the August number of the GAZETTE appears a communication from Dr. Sampson Pope concerning "a new remedy for night-sweats." If you will allow me a few words on the subject I will endeavor to show the readers of the GAZETTE and also Dr. Pope that the new remedy will turn out an old acquaintance, only in a new garb. Dr. Pope, after a good deal of circumstantial talk with no particular bearing on the subject, tells us that he got it from an old negro, but he is kind enough to inform us that King recommends it. (Curious! how can it then be new?) The remedy in question I find to be *Potentilla* (tormentilla) *sarmentosa* (canadensis). It is the American analogue to the European *Potentilla tormentilla* (*Tormentilla officinalis*), or tormentil, a drug very rich in two peculiar tannic acids,—the tormentil and kinotannic acids. Now, I am sure Dr. Pope knows full well that tannic acids of all descriptions have been highly recommended for "sudamina," no matter what is the cause. The active principle of tormentil being its peculiar acids (tannic), it is clear that tannic acid is the principle from which Dr. Pope gets his *wonderful* effects in the *new* (old) remedy. If our new "Sampson" had studied his

therapeutics not from irregulars and quacks and negroes, but from regulars only, in their standard works he would have found on reflection that a few grains of tannic or, still better, gallic acid would have accomplished the same wonderful effect and with more precision than the new godsend, the cinquefoil, can or will do. The *Potentilla* (tormentilla) *sarmentosa* is so similar to the European septfoil, or *Tormentilla officinalis* (*Potentilla tormentilla*), that there can be no reasonable doubts about their analogous therapeutic action. The latter remedy has since time immemorial been in use among the peasantry of Northern Europe for all diseases where an astringent remedy was indicated, and I am positive Dr. Pope will agree with me that sudamina from any cause is one of the conditions in which astringents would be indicated. But among the medical fraternity this old, now obsolete, remedy has had to share the fate of so many other time-honored drugs, namely, oblivion. Although it still keeps its place among recognized drugs in many Pharmacopœias, it is now rarely used by the profession. It has left place for more certain and upon more active and effective based drugs than it; for example, atropine, tannic acid, gallic acid, ergot, agaricine, picrotoxine, etc. Its usefulness was at an end, its doom was sealed, and so I think the new remedy of Dr. Pope will be. There is no need in our armamentarium for rubbish of an obsolete character.

Respectfully,

OSCAR ALF. FLIESBURG, Ph.G., M.D.
HUDSON, WIS., September 4, 1887.

Notes and Queries.

OXYGEN AS AN ANTIPYRETIC.

At the last session of the Royal Academy of Medicine of Madrid, the President introduced an innovation by allowing SEÑOR DON DR. FRANCISCO VALENZUELA, a non-member, to read a paper. The subject was, "The Effect of Oxygen of High Tension upon the Animal Organism," and the amount of original investigation reported in it may well serve to justify the President of the Academy in departing from the time-honored custom of confining the papers and speeches to academicians. Don Valenzuela began his researches by submitting rabbits to pure oxygen at various pressures. No effect on the temperature was produced at a lower pressure than seven hundred and

sixty millimetres, or five times the ordinary tension of the oxygen in the atmosphere. Under this, however, a rabbit whose initial temperature was 38.7° C. after an hour's sojourn in the chamber presented a temperature of 37.9° C. At still higher pressures of pure oxygen greater falls of temperature occurred. The highest tension at which experiments were made was fifteen hundred and twenty millimetres; this reduced a rabbit's temperature in an hour from 38.4° to 32.2°. The general effect on the animals of oxygen at the higher tensions was to produce a temporary torpor, and they came out of the chamber covered with moisture; in a very short time, however, they entirely recovered their ordinary condition. Some experiments were also made on the effect of oxygen of high tension on the febrile state, by inducing septicæmia in rabbits and comparing the course of the disease in those which were subjected to the action of oxygen with that in others kept under ordinary atmospheric conditions, with the general result that pyrexia appeared to be reduced by the sojourn in the oxygen chamber. In one case two rabbits were each inoculated with a cubic centimetre of serous fluid with a putrid smell from a dead body. One of them was then subjected for two hours to the action of oxygen of a tension seven times higher than that which it has in the air. Four hours subsequently the temperature showed a reduction of 1.7° C., the temperature of the other rabbit at the same time being 3° C. higher than the normal. The next day the body heat of the first rabbit was 1.5° C. and the second 3.1° C. above the normal. The first was replaced in the oxygen chamber under the same pressure, and for the same length of time as before, which reduced the temperature 2.2°,—that is to say, to 0.7° below the normal. On the third day it was only 1° C. above the normal, while the second rabbit died. No further treatment was resorted to, and on the fourth day the first rabbit had regained its normal physiological condition. It was found in the various experiments made that when a small quantity of septic matter only was introduced, a single session in the oxygen chamber was sufficient to destroy the effect of the virus, but that if a high degree of sepsis was induced the poison was only partially destroyed by a single session. Dr. Valenzuela then made some observations on patients. A young man was attacked by pneumonia, affecting both lungs, on April 26. On the morning of the 27th the temperature was 39.5° C., and in the evening

40.4°. He was then put into the pneumatic chamber containing pure oxygen at a pressure of nine hundred and fifty millimetres, or six times the ordinary tension of atmospheric oxygen, for an hour, after which his temperature was 1.7° C. lower. The next morning it was 39.2°. A second session in the chamber produced no immediate reduction, but four hours later the temperature was 39°. That evening it was 39.5°, and it gradually returned to normal, though no further sessions in the oxygen chamber were ordered. The man made a rapid recovery. Dr. Valenzuela likewise mentioned some other cases of pneumonia and tuberculosis on which the oxygen treatment appeared to have a beneficial action.—*The Lancet*, June 4, 1887.

BUTTER AND OLEOMARGARINE.

The following is quoted from Professor Atwater's article on "The Digestibility of Food," in the September *Century*: "Much has been said and written about the relative digestibility of butter and oleomargarine. The only actual comparative tests on record are a series made with a man and a boy by Professor Mayer, in Holland. In these from 97.7 to 98.4 per cent. of the fat of the butter and from 96.1 to 96.3 per cent. of the fat of the oleomargarine were digested. The average difference was 1.6 per cent. in favor of the butter. Certain possible sources of error in such experiments make it a question whether the digestion was not in fact more nearly complete than even these figures make it. An interesting series of experiments in artificial digestion, conducted by Dr. R. D. Clark, in behalf of the New York Dairy Commission, though of course not affording a definite measure of the process as it actually goes on in the body, accords with the very natural supposition that, in ease, and perhaps in completeness of digestion, oleomargarine would rank between butter and the fat of ordinary meat.

"In chemical composition oleomargarine stands between meat-fat and butter. It will be remembered that oleomargarine is made from beef-fat and lard by removing from them part of the stearin, which counts as the least digestible ingredient, and adding a little butter and sometimes oil, as cotton-seed oil. The bulk of all these fatty substances, meat-fat, butter, and oil, consists of the same or nearly the same kinds of fat, the meat-fat having the

more stearin. The butter, however, contains small quantities, seven per cent. or thereabouts, of peculiar fats, butyrim, caproin, etc., which give it its flavor and which are thought by some to make it more easily digestible, especially by persons whose digestion is enfeebled by lack of digestive juices or otherwise.

"In the excitement over oleomargarine legislation the discussion of the relative digestibility of butter and butter substitutes has been made very active by the importance of its bearing upon their comparative values for nutriment, and many statements have been made as to the effect of the chemical composition of the peculiar butter-fats and the consequent chemical changes in the process of digestion and assimilation in the body. It is interesting to compare the very positive inferences which some writers upon the subject draw from experimental investigations, with the very guarded expressions of opinion made by the authors of the same investigations in their writings and in personal conversation. The facts at hand and the general impression of special students of these subjects, so far as I have observed, are to the effect that probably, for healthy persons, the difference between butter and oleomargarine in ease and in completeness of digestion would be at most very slight, but that for people with enfeebled digestion and for infants, butter may, perhaps, at times, have the advantage."

NEW TEST FOR MILK.

A new test for water—that is, pump-water—in milk has recently been proposed by HERR SZILASI. This depends on the fact that sulphate of diphenylamine is colored blue by the action of an exceedingly dilute solution of a nitrate. As well-water always contains more or less nitrate, its presence in milk can be detected. The test is carried out thus: Twenty minims of sulphate of diphenylamine is placed in a small porcelain vessel, and a few drops of the milk which is to be examined added to it. If this contains even five per cent. of average well-water, a blue tinge will gradually distinctly appear. Sulphate of diphenylamine is easily procurable, and only costs about sixpence an ounce, so the test may be readily tried.—*The Lancet*, June 11, 1887.

ANTITHERMIC MEDICAMENTS CONSIDERED AS SEDATIVES OF THE NERVOUS SYSTEM.*

BY PROFESSOR DUJARDIN-BEAUMETZ, Paris, France.

GENTLEMEN:—I think that we may fitly characterize the age in which we live as one in which great advances in the healing art have been made. Every day brings to light some new discovery in therapeutics, and while the value of human life goes on increasing, we

* A lecture delivered in Cochon Hospital, and designed as an appendix to "New Medications." From advance sheets.

are continually put in possession of new and precious means of mitigating the infirmities and lessening the physical discomforts of human existence.

In previous lectures delivered during the scholastic year 1884-85, I studied with you the antithermic treatment and the new agents just coming into use for the reduction of fever temperature. To-day I am going to speak to you of another still newer antifebrile remedy, but shall not repeat the general considerations concerning the antithermic medication presented in my former course,† and I have nothing to alter of what I then said. I wish only to call your attention to a property of

† See THERAPEUTIC GAZETTE, vol. for 1885, p. 577.

these antithermic medicaments which has but recently been brought to light, and which is destined, perhaps, to render more service to therapeutics than that even of lowering the bodily temperature.

When I studied the physiological properties of the new antithermics, I brought before you an interesting fact that a certain number of these medicines act, not by lowering the febrile combustions, as was at first believed, but by a direct and special influence upon the thermic centres of the spinal cord. It is this special action which has suggested the idea of utilizing these antipyretics in affections of the nervous system which are independent of fever, and clinical experimenters have been gratified by the results which have been obtained along this line of investigation.

Salicylic acid has taken its place among the analgesics, and has been employed with success in neuralgias and even in *tabes dorsalis*. The same may be said of antipyrin, and it may be affirmed that this substance is almost the peer of salicylic acid in the treatment of acute rheumatism, and without possessing the disadvantages of the latter. But it is particularly to antifebrin or acetanilide that I desire to call your attention, and it is with the consideration of this new therapeutic agent that I shall begin what I have to say to-day.

Acetanilide is a substance which has been long known, but has hitherto possessed only a chemical interest, not having entered the domain of medicine. Its discovery was due to Gerhardt in 1835, who obtained it by the reaction of chloride of acetyl on phenylamine. It was only last year that the attention of physicians was attracted to this product of the laboratory, and it is to Cahn and Hepp, assistants at the clinic of Kussmaul, of Strasbourg, that the merit belongs of having for the first time studied the antithermic action of acetanilide, to which they gave the name of antifebrin. For my part I am disposed to repudiate the name of antifebrin as being ill chosen, and as indicating, as we shall see, only the least important property of this product, and I shall use in preference the name of acetanilide, which was given to it by Gerhardt, and which has the advantage of expressing its chemical composition.

A short time after the first clinical trials were made, Prof. Lépine, of Lyons, studied in detail the physiological and clinical properties of this medicament. After having ascertained by experiments on animals the action of this substance on the temperature, on the circulation, on the elements of the

blood, and on the nervous system, Lépine employed acetanilide in apyretic diseases, and it is to him that the honor belongs of having found that this new medicine is not only powerfully antithermic, but also a most useful nerve.

I have myself, in my hospital service, made interesting experiments, which you have many of you witnessed. The results of my clinical observations and of researches made in my laboratory have been recorded in the inaugural theses of two of my pupils, Weill and Arturo-Reyes y Sardiña, and these are the results which I am going to present to you to-day.*

Acetanilide, as it is found in commerce to-day, is a substance of a beautiful pearly-white color, very crystallizable. When carefully purified, it has no odor, and possesses a slightly pungent taste, which is not disagreeable; hence patients take it readily. It is very slightly soluble in water, and this would be a great drawback to giving it in solution were it not for the fact that it dissolves in alcohol with great readiness.

The mode of preparation of acetanilide is very simple. All you have to do is to act upon aniline with glacial acetic acid, and before this medicament became an industrial product we used to make it constantly in our laboratory. I need not take up your time with the details of the process, which you will find described at length in the theses of Weill and Reyes.

The chemical study of acetanilide was made in a very thorough manner in Germany by Menshutkine,† in 1882, and this chemist has shown that in order to obtain acetanilide in a state of purity it is necessary always to employ an excess of acetic acid. This fact has had an important practical consequence, leading to an increase of the supply and a fall in the price, which has now gone down to ten francs per kilogramme, and I need not tell you that the cost of a drug is an element which is always to be taken into account when its administration is to be long-continued.

From a chemical point of view, the constitution of acetaniline may be interpreted in the following way. This substance has for its formula C_6H_5NO . It may be considered

* *Vide* Weill, "On Acetanilide" (Thèse de Paris, 1887); Arturo-Reyes y Sardiña, "Contribution to the Physiological and Therapeutical Effects of Acetanilide on the Nervous System," 1887.

† Menshutkine, *Journ. de Pharmacie*, May 15, 1887, p. 520.

as composed of aniline in which one atom of hydrogen has been replaced by the radical acetyl :

Now, aniline itself may be regarded as ammonia in which one atom of hydrogen is replaced by the radical phenyl, C_6H_5 , and from this point of view acetanilide may be considered as an ammoniacal compound, in which two atoms of hydrogen have been replaced, the one by the radical phenyl, the other by the radical acetyl :

In other words, we might apply to it the name of *phenyl-acetamide*.

When employed as a medicine, acetanilide, I need not tell you, ought to be perfectly pure. All impurities which the aniline of commerce may contain ought especially to be eliminated. The following are the characters which, according to Yvon, should belong to medicinal acetanilide :

1. It should possess no odor.
2. It should be perfectly white.
3. Heated on a platinum foil, it should give a colorless liquid.
4. When thus heated, it should be entirely volatilized, leaving no residue.
5. It ought not to give with hypobromite of sodium an orange-yellow precipitate.

This last reaction, which is very delicate, is obtained whenever acetanilide retains any traces of free aniline.

Acetanilide is always of easy administration. It may be given in capsules or in solution. Water being, as I have told you, an improper vehicle, it may be given in wine, to which it does not communicate any disagreeable taste. One may employ to advantage the following formula :

R Acetanilide, 5 parts;

Simple elixir (or elixir of Garus), 170 parts. M.

A tablespoonful contains 50 c.g. ($7\frac{1}{2}$ grs.) of the medicament.

The doses may vary from 25 centigrammes to 3 grammes in the twenty-four hours, but whatever may be the daily quantity prescribed, it must not be given in one full dose, but in several small doses of 50 centigrammes or more, administered at regular intervals during the day. By giving the entire amount

in one dose you would run the risk of witnessing collapse and cyanosis.

Let us first study the physiological action of acetanilide. In weak doses (*i.e.*, 2 to 4 centigrammes per kilogramme of the animal's weight) acetanilide has little perceptible action on man or animal in the physiological state. When administered in subcutaneous injection to hares and guinea-pigs, or introduced by means of the oesophageal sound, it produces no disturbance, no depression of the temperature.

Weill himself took four grammes of acetanilide in wine, and the result of the experiment was negative. The temperature, taken every quarter of an hour, remained stationary, and the tracings of the pulse after and before the dose indicated no modification.

In larger doses (25 to 50 centigrammes per kilogramme of the animal) acetanilide is toxic, and the animal is completely overcome. There is marked stupor and prostration; movements become difficult and hesitating; the temperature falls steadily. The respiration is first slowed, then it loses its regular rhythm, stopping at certain moments, and immediately after becoming tumultuous and precipitate. At this period collapse generally sets in. The animal loses all feeling; if you pinch, prick, or burn any part the reaction is feeble and incomplete; to the analgesia succeed anæsthesia and death. Generally death does not supervene rapidly, the absorption of acetanilide being ordinarily delayed from twenty-four to thirty-six hours.

This fact is to be borne in mind, for it seems to show that acetanilide is not by itself a true poison, but that it acts probably as a toxic by robbing the blood little by little of certain principles indispensable to calorification, causing thus a progressive refrigeration which is incompatible with life. This fact seems proved by the researches of Lépine and Weill, which have shown that if you will leave animals poisoned by acetanilide in a warm place you will enable them to recover from the effects of the toxic agent.

The changes in the blood are very important to note. In our experiments on animals, we have remarked a considerable diminution in the quantity of the oxyhæmoglobin. Thus in hares we once saw the hæmoglobin fall from 12.5 per 1000, the normal figure, to 5.5 per 1000, when death ensued. The spectroscopic examination of the blood reveals important changes in the optical composition. According to Lépine and Aubert, there is seen in the spectrum of the blood of animals

poisoned by acetanilide a characteristic ray between C and D, indicating the presence of methæmoglobin. To sum up, the principal alterations of the blood are the marked diminution of the oxyhæmoglobin at the same time that methæmoglobin appears. Quite recently Henocque has studied anew this action of acetanilide on hæmoglobin, and has shown that this agent diminishes the quantity of oxyhæmoglobin as well as the activity of the exchanges.

Despite the sensitive reactions which acetanilide presents, it is impossible to discover the least trace of this substance in the urine of patients to whom it has been administered. It is not then eliminated in substance, and in the present state of our knowledge we can only conjecture as to how it is eliminated.

Acetanilide is almost entirely devoid of antiseptic properties. It has been studied from this point of view by Miquel, director of the micrographic service at the meteorological observatory of Montsouris. According to his experiments, one may incorporate considerable quantities of acetanilide with culture-liquids without impeding or retarding the development of atmospheric bacteria there vegetating.

We come now to the therapeutic applications. As an antithermic, acetanilide is a medicament of but moderate energy, which depresses the temperature by acting on the nervous system and on the respiratory power of the blood. Moreover, its antithermic action is unequal; in small doses we have seen it both produce and fail to produce a considerable thermic fall. Moreover, it frequently causes cyanosis. Acetanilide, then, has shown itself to be very much inferior to antipyrin as an antithermic, and it decidedly resembles phenic acid in its physiological action. Therefore, for my part, I opine that acetanilide, like phenic acid, ought to be discarded as an antipyretic. But as a nervine medicament, acetanilide is a precious acquisition to therapeutics, and from this point of view the experiments undertaken by Prof. Charcot in his hospital service are in perfect accordance with my own.

I must assure you first of the complete innocuousness of acetanilide in affections which are not febrile, while in febrile maladies, and particularly in typhoid fever, this same medicine, even when given in small ($\frac{1}{2}$ -gramme) doses, is liable to produce cyanosis, and may depress the temperature three degrees or more, as I saw in one case. Administered in conditions of apyrexia, however, it may be

taken in much larger doses without producing any appreciable physiological effect. Nevertheless, while in certain patients acetanilide in doses of 2 grammes a day continued even for months produces no manifest physiological effect, in others, on the contrary, the same daily quantity, though given in fractional doses of only $\frac{1}{2}$ gramme, causes a well-marked cyanosis; but this cyanosis does not appear to be harmful. It has been impossible thus far to explain this difference of action, which seems to depend on the activity, greater or less, of the gaseous exchanges in the blood.

In patients not febricitant, and who are good subjects for this medicament on account of its agreeing well with them, no cyanosis or other unpleasant symptom resulting, these are the therapeutic results which we have obtained. I have combated by acetanilide three orders of phenomena,—the element of pain in general, then the special pains of locomotor ataxia, and lastly epilepsy.

In reference to its influence on pains in general, acetanilide has shown itself to be inferior to aconitine in the treatment of facial neuralgia; but when the pains in the head are linked to nerve-alterations, as, for instance, in certain cases of neuritis of the nerves of the orbit, acetanilide has been found superior to every other medicament. I may cite in this connection the instance of a patient suffering from most intense cephalic and periorbital pains, which completely disappeared with the administration of a gramme and a half of acetanilide. These pains had resisted for months full doses of aconite, bromide, and iodide of potassium. I have also obtained good results from acetanilide in the treatment of rheumatic, muscular, neuralgic, and even articular pains, and in these cases this medicament seems superior to salicylic acid, not so much by its general effects, as because it never gives rise to the cerebral disturbances which salicylic acid occasions.

Dr. Demiéville, of Lausanne, in a communication read at the meeting of the Vaudois Medical Society, has given an interesting study of acetanilide as a nervine medicament, which completely confirms my own researches.* He has shown that the abatement of pain begins to be felt a very short time after the administration of the medicament, the relief being frequently experienced in the course of a quarter of an hour. Generally, however, the pain does not entirely disappear

* "On Antifebrin as a Nervine" (*Revue Méd. de la Suisse Romande*, June 15, 1887, p. 305).

till an hour or two after the medicine has been taken. Moreover, acetanilide, according to this authority, has very marked somniferous qualities, and, as a consequence of its administration, there is not only the cessation of painful symptoms but also a strong desire for sleep. Demiéville has administered acetanilide chiefly in sciatica, in intercostal and other neuralgias, and has obtained excellent results.

But it is in the lightning pains of locomotor ataxia, so varying in their manifestations, that acetanilide renders us special service. You can see in our wards several patients affected with *tabes dorsalis*, who used to suffer continually from the painful crises so common in this affection, and who have been completely relieved by the employment of this medicament. Dr. Signé, in his inaugural thesis, written under the direction of Prof. Grasset, of Montpellier, has mentioned cases similar to my own.

In a certain number of patients the effect of this medicament is lasting,—that is to say, the pains disappear as long as the use of the medicine is continued, to return when the effects of the latter have passed off; but it must be borne in mind that in most cases the amelioration is but transient. After having for a fortnight or so obtained marked benefit, the acetanilide fails any longer to relieve them. This is what has happened to one of our patients, who is suffering from dorsal *tabes* with hyperæsthesia of the cord, which dooms him to a most painful form of spinal epilepsy. For fifteen days these painful symptoms, which had resisted all previous treatment, yielded to acetanilide, but since then, despite an increase of the dose from one and a half to three grammes a day, no further benefit could be obtained.

Making all due allowance for disappointments and failures, this new remedy has proved of great utility in this disease, and we have another valuable means of combating the pain which is so prominent and persistent a symptom. Of course we have no pretension to cure dorsal *tabes*, but what we can affirm is that the *douleurs fulgurantes* are often amenable to acetanilide. Fischer has also noted this sedative action on the nervous system in ten ataxic patients to whom he administered acetanilide. Only one failed to derive relief, while all the others were signally benefited.

I consider this fact as of great moment, for heretofore, apart from hypodermics of morphine, the disadvantages of which you know, and which so soon lose their effect, therapeutic

art has been but meagrely provided with anodyne medicaments.

It remains for me to speak of epilepsy in this connection. To enrich therapeutics with a medicine capable of curing this frightful malady would be to render a precious service to humanity, and it must be confessed that, apart from bromide of potassium, which, despite its drawbacks and shortcomings, still remains the best means that we have of treating this disease, our therapeutic arsenal is very poor in really active remedies. I have administered acetanilide for epileptic fits, but the small number of successful cases which I have observed does not warrant me in drawing formal conclusions. In one case, however, I obtained results which were really demonstrative. The case was that of a child, 12 years of age, of respectable intelligence, who for a year had been subject to epileptic fits which were very characteristic, and had been observed by Drs. Gilles and Stackler. We agreed, on consultation, to put this child on the bromide treatment, but having been obliged steadily to increase the doses up to eight and ten grammes a day, we soon had symptoms of bromism, which obliged us to suspend the treatment. I then ordered acetanilide in the dose of $\frac{1}{2}$ gramme three times a day. This treatment has now been continued for three months, and there has been no repetition of the fits. Never before since the onset of the disease has there been so long an exemption from the convulsive crises.

Lépine has also observed cases of epilepsy where acetanilide has had a favorable influence. But I must confess that since I have made a general use of this medicament in the treatment of epilepsy, I have had more failures than successes. The cases observed in the service of Prof. Jolly, of Strasbourg, and reported by Salm, and those noted by Faure in the service of Dr. Denis at the Infirmary of Bicêtre, have shown that in the greater number of cases of epilepsy, acetanilide has been found to be without efficacy. It is, then, a medicine on which we cannot reckon as an anti-epileptic.

I must now speak to you about the analgesic action of antipyrin. In previous lectures I have dwelt on the influence of this medicament on the temperature of febricitants. I shall not return to this subject, having nothing new to add, antipyrin remaining still one of our best antithermics, but I wish to call your attention to a new and very important property of this medicament.

From the date of the first applications of

antipyrin to therapeutics, it has been employed in the treatment of rheumatism, and since early in 1884 Alexander has noticed its good effects in calming the articular pains. These observations have been confirmed by Demme, Demuth, Masius, Bernheim, Lenhartz, Neumann, Clement, Blanchard, Moncorvo, Fraenkel, etc. Then, in consequence of its proved analgesic action in this disease, it was employed in other painful affections, and two years ago it was recommended by Khomiakoff and Livoff in migraine, while last year White and Sprimont, in their turn, found it to be of utility in hemicrania. But we are indebted to Prof. Sée, in recent communications to the Academy of Sciences, for the most striking demonstration of the analgesic properties of antipyrin.*

Prof. Sée was desirous of ascertaining by experiments on animals how antipyrin could bring about the cessation of pain. In operating on dogs he noted the following phenomena :

1. A very notable diminution in the general sensibility, and a real analgesia in the member which received the injection of the remedy, sometimes also in the opposite limb.

2. The electrical excitation of the sciatic nerve in the animal under antipyrin produces only a very feeble reflex contraction, indicating the enfeeblement of the sensory perceptivity and reflex activity of the spinal cord.

Chouppe, moreover, has arrived at similar conclusions by a different path. By a series of experiments, which he has communicated to the Society of Biology, he has shown that if in dogs you inject what would ordinarily be fatal doses of hydrochlorate of strychnine, after having introduced into their system a certain quantity of antipyrin, not only does the animal survive, but you do not even always provoke strychninism. It seems, then, demonstrated by this that antipyrin appreciably modifies the reflex power of the spinal cord.

Sée, "On Antipyrin as an Analgesic," *Acad. des Sc.*, April 18, 1887.

In acute rheumatism, antipyrin may take its place by the side of salicylate of sodium. Sometimes, even, it is found to be superior to the latter, and under its influence we have seen attacks of rheumatism subside which had resisted the salicylate combined with local revulsion. Ordinarily, the fluxion and pain in the joint have yielded at the end of several days, and have not returned. It is certain that the action of antipyrin in acute rheumatism of the joints is neither more intense nor more rapid than that of sodium salicylate. It, however, has the advantage over the latter of not giving rise to the cerebral troubles sometimes caused by the sodium salt. The dose of antipyrin in rheumatism varies from 4 to 6 grammes (3i to ʒiiss) in the twenty-four hours, and in these doses (1 gramme every four to six hours) we witness cessation of the pain, without the supervention of any cardiac or renal troubles.

Drs. Bernheim, of the faculty of Nancy, and Simon, alumnus of the same faculty, have published an important work on the employment of antipyrin in the divers forms of articular rheumatism. Their numerous and interesting observations accord with the facts which I have myself observed in my hospital service, and they have obtained excellent results from antipyrin without any unfavorable accompaniment, unless it be a slight nausea in some patients.

But it is especially in the nervous troubles of the sensibility that antipyrin does good. All the neuralgias are tributary to its action, and you will obtain the best effects in sciatic and facial neuralgias. Under the influence of a small dose of 2 grammes one will often see these atrocious pains rapidly disappear.

Migraine may also be cured by antipyrin, which has proved to be certainly the best remedy which we possess for this painful disease. Administered at the onset of the paroxysm, it has considerably diminished the intensity of the latter, and if it is given as soon as the first premonitory symptoms make their appearance, it is pretty sure to abort the attack. In any event, it always brings marked relief, and the number of failures is relatively small. The medium dose of antipyrin to administer in migraine varies from 1 gramme to 1½ grammes. Antipyrin will also allay the lightning pains of tabes dorsalis; and here it may be affirmed that it is superior to acetanilide, for it is more certain than the latter, and has none of its drawbacks. It does not produce cyanosis, and its effects on the system are not so soon worn out.

There is, lastly, according to Professor Sée, a group of painful affections which are equally amenable to antipyrin. I refer to the pains of angina pectoris accompanying certain diseases of the heart, especially those of the aorta and coronary arteries. These thoracic and cardiac pains may disappear like magic after the administration of a few gramme doses of antipyrin.

The solubility of antipyrin renders its administration easy, and you can give it in capsules or in solution. If you choose the latter form, you should remember that antipyrin has a disagreeable taste. Therefore, in order to disguise this taste, you can flavor your solution with some of the aromatic essences, or give it with simple elixir or rum. Germain Sée advises to administer the dose of antipyrin in a tablespoonful of water, then to wash down the dose with a few mouthfuls of kirsch or toddy. You may then direct your patient to take 1 gramme of antipyrin, and repeat this dose from two to six times a day, giving in this way from one-half an English drachm to a drachm and a half in the twenty-four hours. These doses have no unpleasant effect, unless it be at times to produce a scarlatiniform eruption, which soon passes away. It is necessary to continue the administration of the medicine for a full week, especially if you have to do with rheumatic manifestations.

The remarkable solubility of antipyrin has led to another mode of its introduction. I refer to the subcutaneous method. In his communication* made to the institute the 11th of July last, Germain Sée has shown that we may in a great many cases substitute antipyrin for morphine. Since the introduction of antipyrin into therapeutics numerous physicians had employed antipyrin in subcutaneous injections, and in my own hospital service I had made numerous trials of the same kind, but they all had for their end the production of an antithermic effect. Dr. Lébert, however, has been in the habit for more than a year of employing these injections for various neuralgias.†

The observations of Germain Sée are most conclusive, and you will find the principal of them recorded in the thesis of his pupil, Dr. Caravias.‡ These subcutaneous injections are made with strong solutions, consisting of one-half gramme of antipyrin in precisely the

same weight of water for one injection, and these injections may be repeated from two to four times in the twenty-four hours. The subcutaneous injections are well borne. At the same time, so concentrated a solution may at times be somewhat painful. To avoid, therefore, any local irritant action, you can make your solution more dilute and employ the following formula :

R Antipyrin, grammes v ;
Water, grammes x ;

and inject, as before, a syringe-ful of this solution. If you use this formula, you will have to multiply your injections in order to obtain the effect desired.

In the subcutaneous use of antipyrin as a remedy for pain a real progress has been effected, and we cannot too much felicitate ourselves on the advantages accruing from this discovery, not the least of which is that we can now substitute for hypodermics of morphine, so fraught with peril in many cases because leading to morphiomania, medicaments quite as active, which are unattended with danger.

It remains to say a few words about salol, on which I am now experimenting in my hospital. Salol is, as you know, a white substance, possessing an odor which reminds you somewhat of bitter almonds. It is chemically produced by the combination of salicylic acid with phenic acid. It is also a member of the aromatic series which has already furnished us so many medicaments. Salol was introduced into therapeutics by Dr. Sahli, who made it the subject of a communication to the Society of Medicine of Basle, and shortly afterwards it was studied by Prof. Lépine, whose researches inspired the thesis of Montange, which was approved at Lyons in January, 1887. The difficulty in the administration of salol consists in its insolubility, which renders almost impossible the preparation of a homogeneous mixture. It is well, therefore, always to give salol in emulsion, which may be made with the tincture of quillaya saponaria, or with mucilage and syrup.

What should be the doses of salol? The experiments made in my laboratory by Dubief show that this substance has no toxic properties, and that one may administer to hares considerable quantities, amounting to 2.50 grammes per kilogramme of the animal's weight, without producing any other symptom than a momentary fall of the temperature, a result which shows that salol possesses, like all its congeners, antithermic properties. You

‡ Caravias, Thèse de Paris, 1887.

will then prescribe salol in gramme doses every three to six hours, so that from four to eight grammes may be taken during the twenty-four hours, and you will give the medicine in capsules, which is practically the best mode of administration.

Salol is also a nervine medicament. It allays nervous irritability in acute articular rheumatism, but our experiments seem to prove that it is less efficacious than salicylate of sodium, while it is chiefly in the lightning pains of *tabes dorsalis* that this medicament has rendered us real service. In relieving these patients it enables them to sleep, and to forget for some hours their sufferings. I will add that, like acetanilide, salol is not an antiseptic, and that, according to the researches of Miquel, it does not prevent bacteria from developing in culture-broths to which large doses are added.

As you see, it is still to this series of aromatic bodies that we owe these new medicaments, and there is reason to think that the properties which we have studied belong to this entire group of substances, and that the future has in reserve for us yet more valuable discoveries.

*A FEW PRACTICAL NOTES ON THE USE OF SALICYLATE OF AMMONIUM, APOMORPHINE, SODIO-SALICYLATE OF CAFFEINE, IODOL, AND RESORCIN.**

BY OSCAR A. FLIESBURG, M.D., HUDSON, WIS.

AMMONIUM salicylate has for the last three or four years received some attention from the therapist, and deservedly so. My object in this paper is to bring out a few practical hints on its use. I will not speak about the theories, etc., why this salt ought and should be used in preference to any other ammonium salt or salicylic acid salt in the treatment of fevers. I will only cite the remarks made by Dr. J. R. Burnett, of Neenah, Wis., in a paper read before the Wisconsin State Medical Society at their meeting in 1886, and afterwards appearing in the *Journal of the American Medical Association*, page 654 and following. He says, "But I also ventured upon a radical departure from the outset. I also reasoned that the rational remedy must be ammon. salicyl., for reasons which need be only alluded to. Its germicidal properties, possessed in common by all salicylates, and its

antipyretic and antiseptic powers, would at least give promise of effectiveness in modifying if not aborting the course of fevers. It would certainly avail in hyperpyrexia; it ought to fortify against systemic contaminations from intestinal ulcerations; and whether or not it were to be decomposed in the body, and thus produce a nascent carbonate, it should, in common with all ammonium compounds, serve as a stimulant, which could be strengthened at will by addition of ammonia in excess." I coincide with Dr. Burnett entirely in the first part of this citation, but I take reservation to the latter part of the sentence, inasmuch as Dr. Albert Robin has shown that the salicylates, benzoates, cinnamates, etc., are carried away by the urine in the form of salicylurates and hippurates, those compounds forming by, or rather reducing with, those acids—viz., salicylic, benzoic, cinnamic—combining with some nitrogenous compound, such as glyocol, and giving up in the act of combining a part of its oxygen. But be this as it may, the fact stands undisputed and proven that we, in salicylate of ammonium, possess a sure remedy to reduce temperature, and by its germicidal and antiseptic properties able to abort and shorten the zymotic diseases. I have for some years past been in the habit of prescribing salicylic acid in the treatment of pneumonia (lobar or croupous, lobular or bronchial), in simple and capillary bronchitis, and also to a certain extent in typhoid, but still more in fevers of the puerperium, and never have I had reason to regret this step from the trodden path. In later years I have always prescribed ammonium salicylate as the best form to give it in those fevers, leaving the sodium salicylate to fevers of a rheumatic type. In a paper read before this Society at their last meeting in Eau Claire, I spoke about this salt and apomorphine in the treatment of pneumonia and bronchitis in children in the following words: "I now bring forward the salicylate of ammonium and apomorphine for their intrinsic value not only as expectorants and reducers of temperature, but also for their constitutional and antiseptic properties, and still more as solvents for fibrin and serous fibrin. If M. Robin's theory on fevers is correct, then we cannot in the whole range of antipyretics find a more efficient heat-reducer than ammonium salicylate." I am now more than ever convinced of the truth of this statement. The formula which I have employed has been one part acid to two parts carbonate of ammonium. This leaves a free excess of carbonate of ammonium, but I have not con-

* Read before the Interstate Medical Association at their meeting in Hudson, July 12, 1887.

sidered this a drawback. I always have it prepared in the nascent or fresh state. The dose I have employed has ranged from 5 centigrammes ($\frac{3}{4}$ gr.) to an infant to 1 gramme (15 grs.) or more to an adult, to be repeated as need be every hour or two. I have with those doses been able to reduce temperature in a short time from 105° or 106° to 99° or 100° , and by repeated doses at longer intervals been able to keep the temperature down at that point. At the same time my cases have progressed without much other medication to a favorable end in a shorter time, and with less distress to the patient than by older methods. I have very little inclination to cite cases. I will only say that for the last year I have used it in every case of pneumonia, bronchitis, and croup I have met in children, and in nearly all cases in adults, and always with the same result,—a short uninterrupted course of the disease to the better. From such results I cannot speak too highly of the drug, or use too laudatory words for its use. My time is rather limited to prepare an elaborate paper on the subject, and therefore I hope this will be sufficient to induce some of you gentlemen present to use this preparation in your practice, and that you then will unquestionably be as pleased with its exhibition as I have been.

Apomorphine.—We all know and the most of us have used this therapeutical agent for its emetic effect, but my purpose to-day is not to speak about it as a stomach-revolutionizer or an emesis-producer, but it is to call your attention to this drug in the capacity of an expectorant. For the last three years I have used apomorphine in every case of capillary bronchitis and membranous croup I have met. I must, without exaggerating, have used it upwards of one hundred and fifty times. Whenever I have had the misfortune to meet a case of capillary bronchitis, my habit has been to prescribe alternately a salicylate of ammonium mixture and powders containing apomorphine, the dose varying according to age from 1 milligramme to 2 milligrammes every one, two, or three hours, as urgency of the case demanded. I have always found it to act very promptly, producing an easy expectoration of the thick, tenacious phlegm, which otherwise so often strangles and chokes the unfortunate little sufferer in his futile endeavors to rid himself of this sticky stuff. It produces a watery exudate in the bronchi and bronchioles, which again thins the tenacious phlegm, and in this way makes it easy for the patient to raise this otherwise murdering substance. It also by this transudation bathes

the inflamed surfaces with a non-irritating fluid. It carries away the surplus blood from the arterioles by compressing the lumen of the same, and by this action gives the inflamed surfaces a chance to recover from their hyperæmic state. I do not know of any one having earnestly recommended apomorphine as an expectorant with sufficient data to claim its use as such, Rossbach, who has lately recommended it in combination with morphine, perhaps excepted: he recommends it in chronic bronchitis in adults. Bartholow speaks of it only, "that it has been used, but with too few data to insure its safety." Stillé and Maisch say "it may be used in chronic laryngeal troubles." Wood, to be sure, in his "Therapeutics," says "that Dr. Jurasz commends it as an expectorant, and that he is confirmed by several observers, among them Dr. Werthner,"—who, indeed, seems to be the only one who has used it in this capacity and observed the same effects which I claim for it,—namely, in the early stage, in a few days at the highest, it changes the thick, viscid mucus into a thin, easily-raised fluid; to quiet the excessive cough; and to act as a heart-sedative. But I must sound a tocsin, a warning-bell to toll emphatically against the excessive doses recommended by Wood and said to be employed by Werthner. Wood gives the dose as $\frac{1}{8}$ to $\frac{1}{4}$ of a grain (0.07—0.15 grain) every two hours, and the double amount to an adult. Now, these are, indeed, very dangerous doses; and cannot but bring the remedy into disrepute on account of the necessarily following depressant symptoms bordering on collapse. We know the emetic effect is produced by $\frac{1}{4}$ to $\frac{1}{2}$ gr., and here Dr. Werthner recommends the nearly identical dose as an expectorant. The largest dose I ever administered as an expectorant has been $\frac{1}{10}$ gr. (3 milligrammes) to a child 4 years old; it was exhibited every two hours. I thought afterwards that I never would give it in so large a dose, as the depressant effect was too great. Still, I am sure I have seen just the effects Dr. Werthner claims for it. For this reason I cannot enough warn you to not use excessive doses of this drug,—which I value so highly, and which is capable of doing so much for our little sufferers in time of need,—and thereby become prejudiced against it, all on account of a rash and indiscriminate use of the same. The diseases in which I have found it most valuable are acute suffocative catarrh and true croup. I again refer you to my paper read at the last meeting in Eau Claire, where

I have more fully detailed the use of this most valuable drug.

Sodio-Salicylate Caffeine.—Last year or the year before my attention was called to this salt in some German journal. I afterwards saw it mentioned in the *American Druggist*. It struck me at once that this combination should be particularly useful in certain cases of heart-disease,—for instance, in endocarditis of a rheumatic type, or in pericarditis with effusion, or in acute endocarditis. I therefore had a druggist, Mr. Johnson, of this place, prepare a sample for me. I have now employed it in a few instances.

CASE I.—Mary K., domestic, æt. 16, endocarditis rheumatica, chlorotic, strumous; had been giving salicylic acid for polyarthritides, also salicine in combination with digitalis and nux vomica; rheumatic trouble better, but no improvement of heart-trouble. She had also been taking tr. citro chlor. ferri. Put her on sodio-salicylate caffeine, 0.15 gramme four times a day; improvement from beginning of exhibition of drug; well in fourteen days; heart-murmurs and valvular sounds normal. For chlorosis gave her at the same time pil. Blaudii.

CASE II.—James M. D., millwright, æt. 36, endo- and pericarditis rheumatica. Had a subacute attack of inflammatory rheumatism in beginning of winter, leaving him with this complication. Put him on 0.20-gramme doses four times a day; steady improvement from beginning of exhibition; no other treatment used.

CASE III.—Mrs. P., æt. 32, chronic endocarditis following rheumatism, aortic and mitral insufficiency, pericarditis, congestion of left lung from pressure, anæmia; gave her sodio-salicylate caffeine, 0.10 gramme four to six times a day; quite a good deal of improvement; was when treatment first commenced unable to move around; in a few weeks went to Chicago, and there, through exposure having an acute attack, came under Prof. Davis, Jr.'s, treatment.

CASE IV.—Mrs. T., æt. 33, neuralgia migraine, pain over præcordia, uterine troubles; has had unbearable pains in head and over heart; was put upon 0.20 gramme three times a day when migraine and pain over heart was bad, otherwise morning and night; steady improvement from exhibition of drug.

These cases are the most important I have notes of; have given it a few more times, but have no notes. Of course these few cases are entirely too small in amount to form an opinion from; still, as they have given me

good results I can recommend it for further trial.

The mode of preparing is not very complicated, and I will append the formula Mr. Johnson has been using. The Germans seem to use not only the salicylic double salt, but also the double salts of benzoic and cinnamic acids, and those can be prepared in the same manner as this, only substituting the respective acids instead of salicylic:

R Caffeine (pure), 50 grammes;
Acid salicylic, 32 grammes;
Hydrate soda,
Distilled water, aa q. s.;
Salicyl. soda, enough to make 100 grammes.

Heat the caffeine in a capsule (porcelain) with about six hundred and fifty grammes distilled water, add the salicylic acid till dissolved; then add the solution of caustic soda till nearly neutral; leave it slightly acid; it will even be better to preserve a portion of the acid solution, so if the remainder should be alkaline it can be corrected; evaporate the neutralized solution on water-bath to a granular powder; then powder to an impalpable substance, and to this add enough salicyl. soda to make one hundred grammes by weight.

Iodol.—*Tetraiodopyrrol.*—This substance has of late claimed some attention from therapeutic writers as a substitute for and as superior to iodoform as an antiseptic. If it is superior I do not know; that it is equal to iodoform in many respects I do know. I have used it in about a dozen cases of ulcers of the rectum and erosions of the uterine cervix and indolent ulcers of the leg,—cases where I formerly always employed iodoform. In all those cases the iodol has acted fully as well, and, it seems to me, even better than iodoform. If it will serve me as well in the future as it hitherto has, I shall again report on the subject. Iodol is a yellowish-brown impalpable powder, without smell or taste, insoluble in water, but easily decomposed by light and organic substances. It then gives off the pyrrol, and free iodine will be the result, somewhat similar in this respect to iodoform,—the percentage of iodine is about the same, or ninety-two per cent. in the one and ninety-five per cent. in the other. Its greatest merit lies in its being odorless and non-toxicant, also being very light and impalpable. I see some German authors claim good results from it in the treatment of laryngeal phthisis and epithelioma. From my experience I should be inclined to think it valuable in those affections.

Resorcin.—This preparation, which now has been in use for several years, belongs to the phenol group, and is prepared by fusing caustic soda or potash with galbanum, assa-fœtida, or gum ammoniac, afterwards extracting and subliming. It is mostly prepared synthetically from several substances. It has been recommended as an antiseptic, antipyretic, and antifermentative. It was originally introduced as a remedy for cystitis and chronic gonorrhœa. I have for years been using it in the treatment of cystitis, both locally and internally; in both ways it has served me well. For chronic cystitis, used as a topical application in strength of ten per cent. to twenty per cent. solution, it sometimes succeeds when other measures fail. In gonorrhœa I have never used it. But I want to call your attention to its use in cholera infantum, in which I have found it exceedingly valuable. Believing, as I do, that the summer diarrhœa of infants and children always is caused by errors in diet or by changes produced by the excessive heat,—this change mostly consisting in fermentative processes,—I vainly looked about for a good anti-fermentative which at the same time it would stop the formation of the ferments would not be too irritant to the inflamed surfaces of the stomach, and at the same time act as an antipyretic; at last my thoughts concentrated upon resorcin, and for the last three years I have constantly been using it. It has served me well: after only giving a few doses of it the discharges will be nearly entirely odorless, the stomach will regain its wonted strength. The doses I have employed have varied from 3 centigrammes to 50 or more for an adult. In adults I have mainly employed it for fermentative dyspepsia,—i.e., gaseous or flatulent dyspepsia (indigestion). I have also employed it in pertussis on the recommendation of a Brazilian physician, Dr. Freire, I believe. I have used it in the form of a spray, the strength varying from five per cent. to twenty per cent.,—the spray to be faithfully applied every two or three hours, according to frequency of coughing attacks. By the use of those sprays I have been able to cut short every attack of pertussis, and often in two or three days abort this disease, which otherwise runs a course of weeks. I cannot too highly recommend it, especially as it is rather pleasant in its taste, being sweetish, and soothing in its effect. I also think that in resorcin we have a remedy for the bugbear "rose fever," hay fever, summer coryza, or what it may be called. In a spray

of thirty per cent. to fifty per cent. solution applied two or three times a day I have found it of great service. But where resorcin will be and is of greatest utility is in the treatment of infantile eczema of a chronic type, with hard, scaly eruptions, indurated base, and highly-inflamed surrounding tissue, with a violet or dark-red color, showing that the true dermis (vera) is at fault. In those cases I can confidently assure you, gentlemen, that a few applications of a salve consisting of resorcin, oxide of zinc (equal parts), and cold cream (ten parts) will soon bring on a change, causing the eruption to dry up and heal, the inflamed tissues to assume a natural color. Sometimes it will be necessary to use nitrate of silver solution in addition, to be applied a few times, always previous to the application of the salve. This solution should be rather strong, one or two or three grammes to thirty grammes. It will also be found of great service in the treatment of all other scaly eczemas of a chronic type. In the acute type it is of very little service. It is of value in the treatment of psoriasis, prurigo, eczema barbæ, acne rosaceæ, and other skin-diseases of the same character.

*SIERRA SALVIA, OR ROCKY MOUNTAIN
SAGE.*

BY A. COMSTOCK, M.D., WESTCLIFFE, COL.

THE readers of the GAZETTE may recall an article printed in this magazine about six years ago relating to the same topic as given above. I then had personally met this plant and observed it for about one year, and was impressed with its value as a therapeutic aid. After the interval of half a dozen years in experience and inquiry I am more inclined to urge the profession to test its virtues than when I knew less of it. This humble plant naturally would attract but little comment from the laity, and has no history in the literature of the land of its habitat. In fact, it shares the fate of nearly every detail of botany in the same region, chiefly, I doubt not, because most people who have passed over this section have been either too indolent or otherwise too occupied to give the leisure required; and further, but a few years have passed since most of the area producing this growth has been released from the native Indian or Mexican. The traditions of those who for centuries have hunted over these plains and mountain-slopes connects the sage

referred to with a long list of local diseases. It is not improbable from all I can learn that it had a high place with several generations of the race we call the American Indian, if not with the Aztecs, the Toltecs, the Moyas, and Ouiches, when they extended a type of civilization over these parts of a better sort than has ever been known since the days of Uxmal and Aunhoc. Any one passing over the plain, after leaving the Missouri River towards the mountains, on any of the central lines of railway travel may have observed a pale-green tuft of leaves, persistently covering part of the dry belt, at almost any elevation from four thousand to eight thousand feet above sea-level. It does not flourish in the rainless belt, but better in the region which secures a rainfall of not less than a dozen inches. The rich pale green is perennial, and after a slight fall of snow has melted it exhibits a gloss of rare beauty in lustre. The plant is perennial, and this appearance is a sequel to the winter blasts which have denuded it of its season's bloom, or what is left from the cropping of the antelope or cattle or sheep when fodder is short. If protection is furnished by fencing, and when the sun reaches its northern June limit, one of these bunches, not larger than the palm of the hand, sends up shoots, if fairly well nourished, a dozen in number, and to a height of fifteen to seventeen inches. The root does not penetrate beneath the surface much beyond half a dozen inches as a tap, and, like the buffalo- (or bison-) grass which it accompanies, must retain a vitality almost anhydrous for some months of the year.

The portion used is the superstructure, which ripens during the latter part of August, but must be gathered for medicinal use in the early stage of bloom, and just as soon as the pale-yellow shade tinges the pollen. The arrangement of the flowers on the stem is of a class known as "indeterminate inflorescence," and of the racemose type. If poorly nourished, it becomes purely and classically a raceme; but under more favorable conditions (say along the margin of an irrigating ditch, or a freshly-made mining prospect) it develops to the more fruitful panicle. The leaf is crenated and fascicled, but not pointed or spicate, nor supplied with silica, but soft as plush. Small bractlets shoot out in rapid succession with the first summer showers, alternate, and about three-fourths of an inch apart, till near the apex, where they are not one-fourth distant. The little green globules expand at the distal part and form a cotyli-

form receptacle for the pistils and stamens. The seed, when ripened, resembles that of a grass named after Mr. "Timothy" Hanson (who introduced about a century since the specimen to England, where it is known as the "cat's-tail grass"), and well known in this country. I have counted fifty seeds in a cup, and between three and four thousand cups from a single root, or about two hundred thousand seeds in grass.

The maladies incident to the region where the plant is found are such as would be natural to expect from the sudden changes from hot to cold, due to conditions so clearly defined and illustrated in the report of Prof. Langley upon high altitudes. A clear sky is overcast with dense clouds, and an evening shower follows which may depress the thermometer from 90° to 50° F. in an hour's time, and hence one exposed and overtaken while riding will suffer from an abrupt and almost complete suppression of the offices of the skin. As a result the kidneys may suffer, or the lungs, or what is here termed the "mountain fever," which uncomplicated involves the upper spine, when the cord is congested in the region of the cervical ganglia, extending perhaps through the entire tract. The chill announcing it is a signal for an active system of relief or a long and tedious convalescence. Whilst quinine was formerly used and seems to be indicated, the dry skin and high temperature with cerebral congestion is best allayed by an infusion of the mountain sage. Other animals than man appreciate it, and in the coldest portions of the year antelope, deer, and even grouse are fond of securing its tonic effect, and will consume of it so freely that late in winter their tissues are flavored with it.

From personal experiment and observation in many climates, from the range to coast, for several years I find it the most effective single ally in cases of periodic fever, rheumatic or neuralgic affections, the exanthemata, diphtheria, and kidney-troubles of the type where a diaphoretic or diuretic is required, of any named in the entire list of *materia medica* products. If taken hot, it at once affects the capillaries, as would be expected from the office of the stomach in digestion, and a free diaphoresis follows. When used cold, it acts upon the kidney in from three to five hours, and often in one-half this time. It should be taken freely diluted, and quite unlike the former teachings in that respect. In wine-glassful portions, and as often as three times per hour till full effects are induced, and with

no prescribed amount, is now my custom. Not more than three-fourths to one-half a drachm of the bloom to a pint of boiling water, and steeped as cautiously as the most delicate cup of tea, or till the fibres settle to the bottom of the china bowl (for no metal should be used), when it is ready for use, and may be taken not as a medicine, but as freely as the patient be inclined, always after retiring to get the best results for action on the skin and to quiet nervous irritation. I am also fond of using the infusion as the basis of a lemonade, if acid is indicated, sweetened, etc., to taste. For a tonic and taken cold, it may be taken in less quantity, say a wineglassful, as the Germans use the hot or cold water for gastric irrigation. In the latter case it may be used stronger, and of late Messrs. Parke, Davis & Co., Detroit, have put up a fluid extract which concentrates the elements in a very neat form. I used to advise a proportion which I am now convinced is too strong, and find about one-half a fluidrachm will be tolerated and act best when diluted with a full pint of hot water and allowed to cool, being meanwhile covered so that none shall volatilize by way of steam. If, however, the infusion from the herb be preferred, do not spoil it by making it too strong, and always prepare fresh every day. For the cases indicated it is not improbable that, when patiently tested, it will become as much a staple as the cinchona preparations of South America, the cloves of South Africa, or the rheum of Asiatic India and China.

CURIOSITIES OF THERAPEUTICS.

BY G. ARCHIE STOCKWELL, M.D., F.Z.S.,
PORT HURON, MICH.

IV. MYSTICAL AND CELESTIAL MEDICINE.

THE belief and teachings regarding a Supreme Intelligence as inculcated within the secret and sacred precincts of the Mysteries, had marked influence upon scientific development and progress. Since the Supreme was the source of All, only by the various paths of knowledge could be reached the "narrow gate" opening upon the "straightened way" leading unto "Perfection."* The

* This was the language of the *Mysteries*; and here is found the meaning of the utterance recorded by Matthew (vii. 14), "*For narrow is the gate and straightened the way that leadeth unto Life; and few be they that find it.*" The word that is translated "*destruction*" in the

educational world at this time was purely scientific: the miraculous was deemed the refuge of timid, inconsequent, and vulgar minds: and it was recognized that all things were governed by laws in which accident and chance had no part. But with the decline of knowledge, it being a mystical and caste privilege, the Truth was buried with the secrets of the Colleges, or survived merely as esotericisms and enigmas, the key to which was soon lost; consequently the exoteric in form of vulgar superstitions chiefly obtained.

The twelve degrees or schools of the Colleges were progressively educative, the ultimate goal being the utmost familiarity with *Matter*, or what is now generally understood by "Life" and "Nature." *Matter* was defined as the *Supreme in verity*,—"that from which all things originate, past, present, and future; that which is without beginning or end; and that to which all things must ultimately return,"—a subtle intangible Ether or Essence, all-permeant and permeable, eternal in existence, omnipotent in power, incontrovertible and everlasting as to fact, without which *nothing* is possible.

The "Nebular Hypothesis" of the present was better known and more completely elaborated in the past.† It was taught that from the Essence the four *Principles* or *Elements* resolved themselves, whence was derived *Form*: and Form with the Essence superimposed gave *Life*, and Intelligence proportional to the relationships subsequently established by development and cultivation, said relationships being capable of stimulation. Intelligence might be strengthened by absorption from the Supreme direct, or indirectly through and at the expense of the Elemental. Life, though essentially and physiologically considered as a part of the elemental and corporeal, in that it is dependent upon the ability of the

subsequent passage, more properly would be rendered ignorance or oblivion. The *Proverbs* of Solomon are especially interesting in this connection, as not only embodying many of the tenets and esotericisms of the *Mysteries*, but as being the best specimen of Mystical language and teaching extant.

† "The world moves," but after all only in a circle. Strange as it may seem, scientific belief regarding organic life,—the molecular theory of Faraday, philosophy of Kant, Schopenhauer, Mac Vicar, Huefland, Crookes, Spencer, etc.,—as formulated by the most advanced thought of the present age, all tend towards the goal apparently reached by the *Mysteries* more than thirty centuries ago. The "universal ether," "ambient fluid," "vital principle," "electro-magnético-intellectual-divine fluid" of various authors, one and all appear as forms of the Supreme Intelligence as defined by the ancient philosophers.

latter to support it, and the latter in turn dependent upon it for continuance, is yet in some sense a unit as a separate and separable intangible *immediate* of the Derivative and superimposed upon the *remote*.^{*} All things save the One are self-limited: each has its rise, fastigium, and decay; and in consonance with this law of the Supreme, corporeal existence is transitory. When the body by process of exhaustion, natural or otherwise, is no longer able to support the Essence, Death follows, when the latter returns to the Original, and the former completes the disintegrating process that resolves it again into the Elemental; and when the Mundane has also accomplished its fastigium, and is again resolved into *Matter*,—i.e., returned to the Supreme,—the body and spirit unite, in that both are merged into the Great Intelligence. This is the origin of the doctrines of the *soul*, of *future state of existence*, of a *resurrection*, etc., that, with the decay of knowledge subsequent upon the perversion and subsidence of Mystical teaching, developed from vulgar exotericisms.

Again, the phenomena involved in œstruation, menstruation, ovulation, and reproduction of the species, manifestly were thoroughly understood in all their psychical and physiological relations. The oldest Egyptian, Hindu, and Chinese records define menstruation or ovulation as the preparation of a germ for the reception of independent life; conception as the sequel to physical conjunction of the two sexes, during which each psychically parts with a portion of its individual essence, whereby is accomplished the vitalization of the germ; gestation is the cultivation and development of the envitalization; and parturition is merely the sequel to such development. In the *Soo-Wan* of Hoangti, written forty-five centuries since, Man is described as a little microcosm, or universe in miniature, and a derivative of the Universal Supreme: and to this lesser microcosm is extended the operation of the *yang* and the *yin*, or, in other words, the *male* and *female* principle existing in the Supreme Essence or Intelligence. This is a near approach to modern theories enunciated at instance of the advanced scientific thought of the present hour embodying the doctrine of Matter and Nature: and inasmuch as everywhere throughout the sphere of living organism certain sexual characteristics presented themselves, the idea represented by the principles indicated as *yang* and *yin* is much more

in accordance with the phenomena of living things than that enunciated by Aristotle, which has so long been generally accepted.

The great secret of the higher Mysteries—the graduation of Perfection, so to speak—followed upon an education that developed to the utmost, *psychical power* and rendering such amenable to the individual will. In other words, it was occultation with the Supreme! This was possible only by most thorough and perfect familiarity with, and comprehension of, the secrets of Nature, the relation of natural phenomena and laws by series one to another, and the application of the power of thought-concentration and mental isolation to the production of biologic conditions, such as we are now pleased to term ecstasy, catalepsy, etc. Simple ecstasy, however, was recognized merely as a delusion, or a neurosis, the physiology of which was probably well understood. The clairvoyance of the ecstatic alone was a source of common error, in that it was *not* a sequel to "*Perfection*," but provoked by influences the reverse of will-abnegation and mental isolation: hence "false prophecy" and "false prophets." The higher Mysteries, however, inculcated a profound self-induced and isolated biologic condition beyond the reach of outside will and of human or mundane influence,—a form of catalepsy in fact, whereby the Essence of the individual was supposed to separate itself from the body and become merged into the Supreme or Universal Essence,—and after being enlightened and purified by this mergence it *might* again be returned to reanimate its mortal clay. This is probably the true meaning of the passage in Genesis that describes Enoch † as "walking with God" ("*moving within the Supreme*," literally), and who subsequently "was not"; he united the Essence of his individuality (soul) with the Supreme Intelli-

† Enoch, or *Cân-ock*, the "Initiated," is perhaps identical with the High Pontiff of Mayax, *Cay* the son of *Can-Ah-dama*. In one instance, as has elsewhere been noted (see THERAPEUTIC GAZETTE, August, 1887, p. 539, Appendix K), his head is depicted along with the heads of Coh and Moo, swinging from the belt of his brother Aac, yet there is no proof *he* was murdered, though the records of the deaths of the other two are unmistakable. Considerable space of time must have elapsed between the tragic demise of the unfortunate Coh and the equally tragical death of his "royal wife and sister," and the accounts of their funerals do not favor mutilation other than was customary to prepare the corpses for incineration and visceral embalmment. I opine the representation of Aac with the heads of Cay, Moo, and Coh at his belt, and their flayed bodies at his feet, typifies usurpation of their properties and powers merely.

* See page 664, foot-note regarding *Trinity*.

gence, but it failed to return and revivify the body.*

The *first birth* was the sequel of the development of the maternal germ upon the reception of Life from and through the parents, and the Essence thus derived was necessarily tainted and weakened by mortality. But by mergence and unity with the Supreme, a *new* or *second birth* was accorded, since the Essence was now derived from the Great Intelligence direct, and practically a part thereof. This makes clear the esoteric language of the founder of Christianity, when expressing surprise and rebuke to Nicodemus:

"Verily, verily, I say unto you, Except a man be born anew he cannot see the kingdom of God. . . . That which is of flesh is *flesh*; and that which is born of the Spirit is *spirit*. Marvel not that I say unto thee, Ye must be born anew. The Spirit breatheth" (or *wind bloweth*, as it is commonly translated) "where it listeth, and thou hearest the voice thereof" (or, *art cognizant of its presence*), "but knowest not whence it cometh or whither it goeth. So is every one that is of the Spirit."—John iii.

Again, Nicodemus inquires, "How can these things be?"—a passage that in the original is far from implying the total ignorance of Mystical regeneration it is made to do by modern translators. As one of the Sanhedrim, and a "teacher of Israel," Nicodemus must needs have been in some degree *Mystai*. But whether insufficiently advanced to properly comprehend all that was implied, or imbued with the scepticism that arose from Roman interference and engraftment, it is impossible to determine. He inquires, rather, *why* such phenomena should exist, and is thereupon promptly rebuked, and referred to the proper source of knowledge,—the Mysteries themselves,—by the words, "Art *thou* a teacher of Israel and understand not these things!" The sentence implies reproach and contempt alike that one of such nominal standing should have ignored the opportunities open to him. Remember that Christ was educated in Egypt and a graduate probably of Memphis! Moses was his prototype! And, like the great lawgiver, he abhorred the ignorance in which his people revelled, and sought to lift them from the slough into which they had fallen, and to a knowledge of higher and better things. His aims, his standards, his teachings, all were Mosaic, and consequently *Mystical*. Forbidden to openly reveal the secrets of the Col-

leges, he took refuge in esotericism,—in parables. Little wonder he incurred the displeasure of the priesthood, since they were alike the exponents of mystical teaching, and the head of the political faction that grasped at power for the few and at the expense of the many; and for years the political branch of the Levitical brotherhood had played fast and loose not only with their own, but the surrounding nations. To them the integrity of the Jewish kingdom was nothing if not accompanied with personal power and aggrandizement. The Mysteries had long lost their purity and truth in Palestine, in that, as in Rome, they were prostituted to improper ends,—individual purposes and political power. Manifestly it was to this prostitution no less than the general degeneracy of the Hebraic race that the "son of Mary" referred when he declared it to be "easier for a camel to go through the eye of a needle than for a rich man to enter the kingdom of God,"—*i.e.*, be united with the Supreme;† and on various occasions he bewailed the general moral and mental apathy of the times, when, with faith broken down under the powerful mental and physical strain to which he had been subjected, he was forced to acknowledge his inability to stem the popular tide.‡

Whether the cataleptic or biologic condition first imposed upon the candidate for Perfection as part of his initiation into the highest Mystery was brought about by the *Mystai*, or self-imposed, is open to some speculation. Probably it was purely voluntary. Other initiations, however, embodied an applied ecstasy, since the accounts thereof that appear in the Apocalypse, the Books of "Daniel," the Books of "Enoch," the "Popul-Vuh," etc., imply both visionary and actual occurrences so intermingled as to be incapable of separation in the mind of the neophyte. "*Perfection*" itself, however, was a self-imposed condition, since otherwise there could be no unity with Supreme; and "*Ultimate Perfection*" was final dissolution,—Death!§

The Masters (Mac or Ephori) in the Perfection of the Mysteries, as the result of education, were well skilled in the production of mental and psychical phenomena and the means of nerve-abnegation and control; the teaching and practice was self-concentration of will and segregation of thought whereby

† Matthew xix. 24; Mark x. 25; Luke xviii. 25.

‡ Luke xiii. 32; Luke xiii. 34, 35; xix. 41.

§ Luke xiii. 32, "Go ye and tell that fox: Behold, I cast out devils, and I do cures to-day and to-morrow, and the third I shall be *perfected*."

* See account of Enoch in foot-note to page 529, THERAPEUTIC GAZETTE for August, 1887.

the Essence (soul) was merged in the Supreme wholly untrammelled by mortality, and whereby true conceptions were had of futurity and space: thus was obtained *prophecy*. It was believed that according to the condition of this Essence or soul at the moment of occultation, so was the result. If the mind was *pure*—*i.e.*, freed from all mundane considerations at the moment of emergence,—and the will of the individual self segregated and voluntarily given to the Supreme, the occultation would be perfect and true; but the impure and trammelled soul must fail of Perfection, and the result consequently be misleading.—Just as two fluids of unlike specific gravity are unable to mingle, so a soul handicapped by mundane influences could not be perfectly merged into the Supreme: and as it must go out to the Great Intelligence impure, so it returned attended by the same earthly error. If pure, it came back imbued with new life and spirituality.*

That knowledge of the higher biologic condition was deemed direct communication with the Supreme is frequently evidenced by the sacred writings of the Hebrews, and constant allusions therein to the "*Spirit of God*" descending upon the "prophets"—*Mac*. These were men of the higher Mysteries, mentally "Perfected,"—that is to say, capable of segregating the mental from the physical. "False prophets," on the contrary, were those possessing knowledge of the *ecstatic* condition, which they mistakenly deemed the higher and *complete* form of *mergence*. By the expert this false catalepsy was defined as the "inharmonious action and relation of the individual *Essence* within itself." Mergence, on the contrary, was harmony of the *individual* with the *Supernal*! Death was permanent harmony, though not complete until the body, which resolves itself into the four original elements, shall be returned to the Essence by reabsorption.

The doctrine of *sin* appears to have arisen from the theory that the *pure* and the *impure* cannot mingle,† hence it was believed that impure Essences were segregated at Death, or under attempted emanation, yet retained their individuality until such impurities were lost. Meantime they were forced to wander in expiation, ever in the midst of (perhaps in absolute contact with) the Supreme, but tortured by inability to resolve themselves. An impure soul having vainly attempted Perfection, since

it could not be improved, must needs become worse, since it is not within the province of anything to stand still; and this is the key to the passage regarding "seven other spirits more evil than himself," and the "last state of that man is worse than the first."‡ Non-mergence and inability to *Perfect*, whether temporary or final, was also typified as "*outer darkness*."

The earliest history of civilized man reveals the prevalence of the doctrine of emanation, and it is easy to surmise its development from and through the Mysticism of Primitivism.§ It was inculcated by the most ancient Maya, Egyptian, Chaldean, Chinese, and Hindu authorities; it was taught by Zoroaster and Mahomet, and is the doctrine of the Lama Buddhists; it is also the foundation of the Vedas, which declare, "In truth there is but one Deity, the Supreme Spirit, and of Him is the *nature and soul of man*." Again, the Vedas, like the Institutes of Menu, affirm the soul to be an emanation of the All-Pervading Intellect, and that, since the latter alone of all the Universe is stable, the soul is necessarily destined to be reabsorbed: further is added, this Essence is without form and visible nature, and with all its beauties and harmonies, is merely the shadow of the Supreme.||

From Vedaism was derived modern Buddhism, the faith of a majority of the human race, that defines a Supreme Being as a part of the Supreme Intelligence: this is the earliest form of anthropomorphosis, and the beginning, doubtless, of the Trinity.¶ It contemplates the existence of an Essential influence that may, if you please, be termed *Force*, giving rise to *Matter*,** and also suggests a soul

‡ Luke xi. 26.

§ See THERAPEUTIC GAZETTE for April and May, 1887.

|| THERAPEUTIC GAZETTE, April, 1887, p. 229; Draper's "Conflict of Religion and Science," p. 132.

¶ I opine the real key to the Trinitarian Doctrine is something as follows. The Essence is triune in that it is the *Derivative* (Tha, or in the Greek *Patha*, translated "father"); the Product (or son of itself); and the Animative (spirit) of all things: truly, the "*Three are One*!" When Christ declares he is "of the Father" (*Patha*) and the "Father of me," he speaks esoterically of higher Mystical knowledge, and refers to his own "*New Birth*."

** In the burning taper the disciple of Buddha sees the effigy of Man: an embodiment of Matter as the sequel to the evolution of Force. If interrogated as to the destiny of the soul he demands, What has become of the flame when extinguished? What was its condition before it was called into existence, before the taper was lighted? Was it nonentity? Was it derived from nothing? Has it been assimilated? See Draper's "Conflict," p. 122.

* Luke x. 22, 24; xi. 34, 35; xiii. 21, 24.

† Luke xi. 24, "When the unclean spirit is gone out of a man, he walketh through dry places, seeking rest and finding none. He saith, I will return unto my dwelling whence I came out," etc.

personality that deludes man throughout his mundane existence, and that is not necessarily extinguished by Death, but perhaps may be lost by progressive stages or degrees. On this latter, too, is founded the theory of transmigration.* Ultimately, however, reunion with the Supreme will follow, when *Nirwana*, or Perfection, will be reached, and oblivion obtained:—a state or condition that has no relation to space or time,—the state into which the flame disappears when extinguished,—that in which Man was before he appeared on the earth and while without individuality, and before the earth even had been called into existence! This is the end all ought to hope for,—viz., reabsorption into the Supreme and Divine Intellect, whereby is obtained perfect mergeance and “*eternal rest*.”

These ideas openly obtained among the higher minds of Europe up to the sixteenth century, when they were partially suppressed by ecclesiastical authority. They did not die, however, but merely slept, to rise and assert themselves anew and more boldly in this present century. In the third century Plotinus taught emanation unchallenged, for the Mystical doctrines were not altogether forgotten. From the Alexandrian Greeks the Saracen philosophers derived it anew, and soon after the capture of the art and literary metropolis of Egypt and the world, the educated Moslems abandoned to the lower and vulgar orders the anthropomorphic ideas of Nature and the Supreme, and the simulachral form of the soul.† A native of Britain, John Erigena, A.D.

* See page 669.

† As Arabism developed into a distinct scientific system, the theory of emanation and absorption became one of its most characteristic features. In thus abandoning vulgar Islamism, the example of the Jews no doubt contributed, for they had exchanged the anthropomorphic being, whose home was behind the veil of the Temple, for an infinite Intelligence, pervading universal space, avowing their inability to conceive of anything which, suddenly and abruptly called into existence, should possess attributes of immortality: they affirmed the soul of man must needs be connected with that which had neither beginning nor end if its immortality was unquestionable! So, too, to-day we find progressive Hebrews in the foremost ranks of scientists, and deriding the anthropomorphic Jehovah of the orthodox Jew.

“In the intellectual history of Arabism the Jew and the Saracen are continually found together. It was the same in their political history, whether considered in Syria, Egypt, or Spain. From these conjointly Western Europe derived the philosophical ideas past and present,—ideas that soon culminated in Aveoroism. Aveoroism is philosophical Islamism; and though we are accustomed to regard Aveorois as the author of these heresies, and the orthodox have so branded him, in truth

800, also taught that every living thing must necessarily proceed from something that had before possessed existence.‡ The visible world, being a world of life, has therefore necessarily emanated from some primordial existence, and that existence is the Supreme itself, who is thus the originator and conservator of all. Whatever is visible to the eye is also maintained by force derived from and as a part of the Supreme, and were that force and supremacy withdrawn it would instantaneously vanish. Erigena thus conceives Deity as an incessant participator in *all* existence, being the upholder, preserver, and derivant, answering to the “soul of the world” expressed by the Greeks. The *particular* life of individuals is, therefore, a part of *general* existence,—that is, of the Essence or “mundane soul,” which is the key to the sympathy existing—though perhaps obscurely to mortal minds—between different individuals, and also widely different classes of life. If the maintaining power is withdrawn, or the body is no longer capable of sustaining it, the former must return to the source whence it was derived to be reabsorbed therein. All visible Nature must thus revert to the Supreme at last. “The death of the flesh is the auspices of the restitution of things and of a return to their ancient conservation. So sounds revert back to the air in which they were born, and by which they were maintained, and they are heard no more; no man knows what has become of them. In that final absorption which, after a lapse of time, must necessarily ensue, the Supreme will be All in All, and nothing exist but in It alone.”§

he was merely a collector, compiler, and commentator of the tenets originally promulgated by the Mysteries. His works invaded Christendom by two routes,—*via* Southern France from Saracenic Andalusia, whence they reached Italy, engendering numerous heresies by the way; and from Sicily *via* Naples, being introduced under the auspices of Frederic II.” (Draper’s “Conflict of Religion and Science,” p. 124.)

‡ John Erigena adopted and taught the philosophy of Aristotle, and indulged in the hope of uniting religion and philosophy in the manner proposed by Christian Ecclesiastics, who were then studying in the Saracenic Universities of Spain. Anastasius, in a letter to Charles the Bold, expresses his astonishment how so “barbarous a man, coming from the very ends of the earth (Britain), and remote from human conversation, should comprehend things so clearly, and transfer them into another language so well!” The general drift of his works was philosophic, but his treatment of such subjects in connection with religion brought him under the ban of the Romish Church, and, after undergoing severe personal censure, many of his books were condemned to the flames.

§ “I contemplate Him as the beginning and cause of all things: all things that are, and those that have been,

Again, Al-Gazzali (A.D. 1010), the most powerful of Saracenic philosophers, wrote: "God has exalted the spirit of man out of a drop of his own light: its destiny is to return to Him. Do not deceive yourself with the vain imagination it will die when the body dies. The form you had upon your entrance into this world and your present form are not the same; hence there is no necessity of your perishing on account of the perishing of your body. Your spirit came into this world a stranger: it is only sojourning in its temporary home. From the trials and tempests of this troublesome life our refuge is God. In reunion with Him we shall find eternal rest,—a rest without sorrow, a joy without pain, a strength without infirmity, a knowledge without a doubt, a tranquil yet ecstatic vision of the source of life and light and glory, the source from whence we came."*

So silently and extensively have these ideas been developed by the education and scientific progress of our time, that it was deemed

but now are not, were created from Him, and by Him, and in Him. I also view Him as the end and intransgressible term of all things. . . . There is a fourfold conception of universal nature,—two views of divine nature, an origin and an end; two also of framed nature, cause and effects. There is nothing eternal but God." (Erigena's "De Divisione Naturæ.")

* "It was in India that men first recognized the fact that Force is indestructible and eternal (see page 662). This implies more or less distinct ideas of that which we now term *force correlation* and *force conservation*. Considerations connected with the stability of the Universe give strength to this view, since it is clear that were there either increase or diminution the order of the world must cease. The definite and invariable amount of energy in the Universe must therefore be accepted as a scientific fact. The changes we witness are *in its distributions*. But, since the soul must be regarded as an active principle, to call a new one into existence out of nothing is necessarily to add to the *force* previously in the world. And if this has been done in the case of every individual who has been born, and is to be repeated for every individual hereafter, the totality of *force* must be constantly increasing. Moreover, to many very devout persons there is something most revolting in the suggestion that the Almighty is a servitor to the lusts and caprices of man, and that, at a certain time after its origin, it is necessary for him to create for the embryo a soul. Considering man as composed of two factors, a body and a soul, the obvious relation of the former may cast much light on the mysterious, the obscure, relations of the latter. Now the substance of which the body consists is obtained from the general mass of matter around us, and after death to that general mass it is restored. Has nature, then, displayed before our eyes in the origin, mutations, and destiny of the material part, the body, a revelation that may guide us to a knowledge of the origin and destiny of its companion, the spiritual part, or the soul?" (Draper's "Conflict of Religion and Science," p. 127.)

expedient in the Papal Syllabus to draw them into open light, and that, too, in the most conspicuous manner. Accordingly, the last Œcumenical, or Council of the Vatican, aiming to throttle, or at least upset, a tendency so obnoxious and dangerous to the tenets of the Romish Church, in an equally prominent and signal manner promulgated among the first of its canons, an anathema of all who dared hold such advanced views.†

There was a broad gulf between the *Masters*, *Mac*, or more advanced of the Mystai, and those who were merely cognizant of the lesser Mysteries, and also between the latter and the great masses of humanity. This was the result on one side of imperfect education, on the other of total and abject ignorance, and in part also of an esotericism that was deemed essential *per se*. This is the secret of discoveries and expressions belonging to the same ages and eras that apparently inculcate conflicting ideas; and it is ever the fault of humanity that it judges of the impressionable rather than the real, whereby history is made up of the details of individuals rather than of the race as a whole of which they were merely factors. Thus, too, popular delusions are accepted as creeds, or as the sequence of laws that in reality are contrary and inimical to such de-

† "Let him be anathema—who denies the one and true God, Creator, and Lord of all things, visible and invisible: who unblushingly affirms that beside matter nothing else exists: who says that the substance or essence of God and of all things is one and the same: who says that finite things, both corporeal and spiritual, or at least spiritual things, are emanations of divine substance; or that the divine essence by manifestation or development of itself, becomes all things: who shall say that man can and ought to, of his own efforts, by means of constant progress, arrive at last at the possession of truth or goodness: who shall refuse to receive, for sacred and canonical, the books of the Holy Scriptures in their integrity, with all their parts, according as they were enumerated by the holy Council of Trent, or shall deny they are inspired by God: who shall say that human reason is in such wise independent, that faith cannot be demanded of it by God: who shall say that divine revelation cannot be rendered credible by external evidences: who shall say that no miracles can be wrought, or that they can never be known with certainty, and that the divine origin of Christianity cannot be proved by them: who shall say that divine revelation includes no mysteries, but that all the dogmas of faith may be understood and demonstrated by reason duly cultivated: who shall say that all human sciences ought to be pursued in such spirit of freedom that one may be allowed to hold as true their assertions even when opposed to revealed doctrine: who shall say that it may at any time come to pass in the progress of science that the doctrines set forth by the Church must be taken in another sense than that in which the Church has ever received and yet receives them!"

lusions. Man, in his great egoism, is unable to conceive of anything higher or more perfect than himself, consequently he measures and judges all things by his own individual limit and standard. To bring the Supreme within the comprehension of the masses, it was found necessary to invoke anthropomorphism; and thus from the *Mâyâ Thah*, Egyptian *Phtha* or *Kneph*, and the Greek and Chaldean *Pathr*, was evolved the word *Father*, "Creator," or "Engenderer."* The God of the vulgar of this nineteenth century is aptly represented in Watt's hymnology as "seated on a great white throne," and heaven as the court of an absolute monarch, with all the paraphernalia of monarchy, enclosed as a "walled city," the "new Jerusalem:" the scene depicted is the extreme of the vulgar barbaric and Oriental. God differs in no particular from the anthropomorphic *Kneph* of Egypt, *Zeus* of Greece, or *Jupiter* of Rome, since all were taught as "majestic," "awful," "omnipotent," "permeant," and "infinite." It is to the exotericisms of the Mysteries as derived from vulgar sources that we must look for the origin of the Deity of popularism: these exotericisms are the paganisms that were engrafted upon Christianity, and which good Bishop Nestor† combated so vigorously and unsuccessfully. Then, aside from being a false or exoteric creation to serve special and vulgar ends, the error is in part the result of misinterpretation of the Hebrew terms, *Elohim* (*worshipped*) and *Jehovah* (*ever-existing*), words that orthographically, and suggestively, possess a plural significance. So, too, the sentence in Genesis that is universally rendered, "God created man in his own image," in the original exactly conveys the meaning found in the *Manava-Dharma-Sastra*: "And the subtle spirit Intellectual took possession, making (of man) a part of itself,"—i.e., man was imbued with the Essence, or the Supreme. Moses, to be sure, inculcated an

anthropomorphic deity in part, and for reasons obvious to any one who will peruse the Mosaic record: yet careful study reveals something grander, higher, and better behind the veil interposed by him between the higher Mysteries and the knowledge of the impure and vulgar. So, too, men high in the Mysteries were regarded with awe by their immediate inferiors because of their near approach to the Supreme. After occultation, whereby was obtained Perfection, they were of the *Supreme*; hence apotheosis, employed as typical of Perfected purity, easily passed the boundary, whereby individuals were elevated to the rank of deities.‡

Again, the wandering essences of the unperfected after death were supposed to be desirous of re-entering upon mortality in one or another of its forms in order to work out their own purification and expiation, and thus obtain the denied bliss; and such essences might be the cause of error in attempts at occultation by those who were not thoroughly endowed with purity. While some might

‡ Immaculate conceptions and divine descents were currently received by the vulgar both before and after Christ's time, so much so that whoever greatly distinguished himself was thought to be supernaturally endowed. In Rome, even as late as the latter part of the second century, no one would have dared deny the city owed its founder, Romulus, to the accidental meeting of the god Mars with the virgin Rhea Sylvia as she went with her pitcher to the spring. "The Egyptian disciples of Plato," remarks Draper, "would have looked with anger on those who rejected the legend that Perictione, the mother of the great philosopher, was a pure virgin that had suffered an immaculate conception through the influences of Apollo, and that the god had declared to Ariston, to whom she was betrothed, the parentage of the child. While preparations were being made for the final campaign against Darius, Alexander undertook a journey to the temple of Jupiter Ammon, which was situated in an oasis of the Lybian Desert. The oracle declared him to be the son of that god who, under the guise of a serpent, had beguiled Olympias, his mother. Accordingly, when Alexander issued his letters, orders, and decrees, styling himself 'king' and 'son of Jupiter Ammon,' they came to the inhabitants of Syria and Egypt with an authority that now can hardly be realized." That the more educated regarded this as nonsense is evidenced by Olympias, the mother of Alexander, who was accustomed to jest of the matter, declaring she wished her son would cease from incessantly embroiling her with Jupiter's wife. There is not the slightest foundation for presuming the son of Mary, who professed to be an imitator of Moses, ever sought or intended to arrogate to himself divine honors: this was the work of his followers and in accordance with the vulgar custom of the times. He sought only to inculcate the tenets taught by the higher Mysteries; and it will be observed that the educated John and astute Luke are wholly reticent regarding the apotheosis of their Master or Teacher.

* When Christ alludes to his death, the meaning attached to the words "I go to the Father"—Greek, *Pathr*—is quite different from that intended. Again, he declares (Luke xvii. 21), "The kingdom of *Pathr* is within you!" And (John xv. 2), "I am the vine (offshoot) and *Pathr* the husbandman (gatherer) . . . every branch that beareth not good fruit he purifieth." When he mentions himself as the "Son" he does so in the same sense as he employs the word *vine*. Finally, it must be remembered his teachings were esoteric; he expressly states this fact, or that they are *parables* (John xvi. 25).

† It will be remembered that the founder of Islam derived his Mystical knowledge, along with the means of procuring and prolonging the extato-biologic condition, from the Nestorians.

imagine they had discovered the means of separating soul and body, as by ecstasy,* unless possessed of the true knowledge (purity) peculiar to the higher Mystai, they were apt to be led astray by these wandering "spirits of evil," and unwittingly, perhaps, exchange souls,—i.e., spiritual identity: this was a prolific source of "false prophecy." It was to preserve the corporeal from such influences—as the vulgar supposed—that it was inhumed, cremated, or placed within the "tower of silence;"† and with like view the Thibetan Buddhists yet condemn the corpses of the poor to be devoured by sacred birds and beasts, while the wealthy, when deemed *articulo mortis*, are assisted out of the world by lifting the scalp and making an opening through the skull, whereby is hastened the escape of the essence, and the body rendered uninhabitable to other essences that may desire to reanimate it.‡

The *Mystai* held disease to be sequel of impression, whereby the harmonious relations of the essence are interrupted. By such inharmony through the medium of the nervous system, morbid changes are induced in the physical.§ The physical or animal portion of

* Plotonius, who taught the doctrine of emanation, believed the soul might be united to the Deity by ecstasy alone, thereby obtaining a foretaste of absorption into the Universal Soul. In like manner Porphyry sought union with God, and bewailed his own worthlessness, saying he had been so favored but once in eighty-six years, whereas his master had six times been so united in sixty years.

† The Parsee, or religion of Zoroaster, was originally a mystical monotheism, its aim being moral and intellectual purity and perfection. It teaches the Supreme in all things. The sun, the fire, the light, all are derived from the Supreme, and are typical thereof, and ultimately must return whence they came.

‡ Is not this the probable cause of the holes found in the vertex of the crania of many of the mysterious extinct race of America known as "Platycnemic Men," or "Mound-Builders"? In certain districts explored by the writer, every skull found was thus perforated by at least one opening, five-eighths of an inch in diameter perhaps, and in some instances, though rarely, by two. Such evidence as is at command leads to the belief, moreover, that the openings were made immediately before or immediately following death.

§ It is now well understood that the ganglionic nervous system is automatically impressionable beyond all source of measure or computation: we can only obtain conception thereof by comparison with other objects. For instance, if a wafer be laid upon a piece of highly polished steel, and the latter then be breathed upon, when the moisture has disappeared, and the wafer removed, the most critical scrutiny, even with microscopic aid, fails to discover the trace of any form; but breathe thereon again, and a spectral image of the wafer comes

the economy is of secondary consideration only, serving only to define an essence,—which, however, is not thereby rendered wholly independent,—a form through which a stream of matter is constantly flowing, receiving supplies from and dismissing wastes into its surroundings, resembling, as Dr. Draper puts it, "a river, cataract, or flame." The particles constituting the physical are inconstant, those present at one instant disappearing the next, its sustenance depending upon the supply. All economies must needs be artificial in nature, since they have not always existed, hence are self-limited, or capable only of three stages,—the rise and development, the acme which encroaches in part upon the other two, and the decay. Nothing stands still in nature, hence when the fastigium is reached, decay with certainty follows, when the vivifying essence returns whence it came, while the body is resolved into the original elements, ultimately to follow its principle. Few modern physiologists, I fancy, will care to dispute these propositions, and they evince greater enlightenment than the world at large, owing to the dogmatic usurpations of theology, has ever been willing to admit. Says Dr. Draper, "In all cases the action of each and every nerve-centre, regardless of its stage, class, or degree of development, depends upon the condition of oxidation. If the supply of arterial blood be for a moment impeded, the nerve mechanism parts with a portion of its power, and becomes more susceptible in its weakness to certain impressions, less so to others: its harmony has been interrupted. If the supply is increased, as when nitrogen monoxide is inhaled, the result obtains as the sequel of more energetic action, and consequently greater nerve waste. This is the necessity that demands sleep and rest as a means of restoring harmony by repair."

plainly into view, and this may be reproduced for months, even years, after the first (and the result of a single) experiment. This proves how trivial an impression may be registered and preserved by an inorganic substance, and that a shadow never falls without leaving a permanent trace, even though it be beyond the power of human vision to detect. (See Appendix L.) How much more impressionable, then, must needs be the ganglia of vesicular nervous material that are constituted special registering *apparati*! Thought is impression, and there is no such thing as spontaneous self-originated thought, for every intellectual act is the sequel of some preceding act essential thereto; and in the origination of thought there must needs be two distinct conditions,—a state of the organism (1) as dependent upon antecedent impression, and (2) on the existing physical circumstance.

Among the vulgar the primitive belief of the derivative origin of disease from* evil essences, universally obtained, and when these took the form of nervous perturbations, such as mania, epilepsy, etc., by the inferior and vulgar they were deemed direct possession by the evil essences of unresolved persons, who usurped the body and its prerogatives to the expulsion or detriment of the original essence. Unable to comprehend the teachings of the *Mystai*, whose exotericisms even were in some measure esoteric, the material essences of the impure that could not enter supreme bliss (be merged into the Great Intelligence) until after expiation and purification,—perhaps not until earth itself should be resolved, when the essence of the body might meet and mingle with that of the soul,—were anthropomorphized in part, whereby arose the doctrine of devils, evil spirits, demons, wandering genii, etc.† Bearing witness in their own personality of the preponderance of impurity or evil, the masses demanded an anthropomorphic spirit to control the force opposed to the pure; hence Dualism, with Pluto and his prototypes. The domain of Tartarus, given to the latter, in time came to

* See THERAPEUTIC GAZETTE, April, 1887, p. 232.

† In the uncertainty as to what becomes of the soul in the interval between its separation from the body and the time it would be again reunited, many different opinions appeared among the unlearned at various different ages. Some thought it hovered over the grave; some that it wandered disconsolate through the air. In the popular belief of Romanism, by an ignorant interpretation of the esotericisms of Matthew xvi. 19, St. Peter sat as a doorkeeper at the gate of heaven, with power to grant or refuse admission at his pleasure. Many were, however, disposed to deny this, since such power would be anticipatory of the judgment, which would thus be rendered needless; consequently after Pope Gregory's time the doctrine of purgatory met with general favor as providing a place for departed spirits. That the spirits of the dead occasionally revisit the living or haunt their former abodes appears to have been a fixed belief in all ages that was by no means confined to the more ignorant. A half-century or century since an enticing pastime was to gather at the fireside of a winter's evening and retail, or listen to, stories of ghosts, apparitions, goblins, etc.; genii are a concomitant of every Eastern tale to this hour, and ghostly narrations are yet common to many Scotch and English hearths. In the old times the Romans had their *lares*, or spirits who had led pure lives, their *larvæ*, or spirits of evil, and *manes*, or those that were of doubtful character. Says Draper, "If human testimony on such subjects can be of any value, there is a body of evidence, reaching from the remotest ages to the present time, as extensive and unimpeachable as is to be found in support of anything whatever, that these shades of the dead congregate near tombstones, or take up their secret abode in the gloomy chambers of dilapidated castles, or walk by moonlight in moody solitude."

be burdened exoterically with various properties in the way of locality, scenery, and surroundings, calculated to appeal to the fears of the ignorant; and as mundane and political considerations usurped the educational and spiritual in the *Mysteries*, so these superstitions were made to serve the ends and aims of a political majority, who, as they became more degraded, adopted them for themselves. The Hebrew *sheol* ("seeking," or place of seeking), and Greek *hades* and *gehenna*† ("shades" and "impurity," referring to the existence of those who were "not in the light"), underwent various transformations, the most elaborate of which, perhaps, is the eighteen-chambered hell of Lamaism, eight of which are freezing cold and ten burning hot.§

(To be continued.)

CARBOLATE OF MERCURY IN SYPHILIS.

DR. SCHADECK has employed carbolate of mercury both internally and hypodermically in syphilis with remarkable success. He gave it in thirty-five cases in the form of a pill without finding it give rise to any gastric disturbance. The formula was,—*R Hydrargyri carbolic oxydati*, ʒiii; *pulv. glycyrrh. q. s. ut. f. massa pil. ex qua form. pil. No. 60*; from two to four pills daily after food. This preparation was originally used by Gamberini in 1886. Dr. Schadeck also employed the carbolate of mercury in ten cases in the form of hypodermic injections, which he administered in the gluteal region, causing the needle to penetrate the muscles deeply. The liquid used was a mucilage containing two per cent. of carbolate of mercury in suspension. In this way his results were as satisfactory as when the preparation was given by the mouth.—*Lancet*, August 6, 1887.

† The word *Gehenna* was applied to a valley in the mountains a short distance from Jerusalem, where was burned the garbage and refuse of the city,—a sanitary measure. Any one connected with this burning or the removal of garbage was of necessity *impure*, as having been in contact with decaying and effete matters. This valley was designated as typical of extreme impurity. The word "outer darkness" or shades, which is so frequently translated hell, appears in the Apostles' Creed, and has been a matter of puzzle to many, but the words "Christ descended into hell" mean simply his spirit passed into the unknown,—*the shades*!

§ Manifestly, the Lamantic-Buddhistic hell is derived in part from some of the hidden workings of the Mysteries.

THE TREATMENT OF OBESITY.

EVERY physician in large practice in America must occasionally have to treat cases of excessive fat-production, although it seems to us indisputable that this condition is distinctly more infrequent in the United States than in Germany or even England. The poorer people of Germany are, perforce, frugal, but the richer classes seem to us to indulge much more freely in excessive eating and light wine- or beer-drinking than do Americans, whose nervous energy and haste "to get on" cast into the shade gastronomic pursuits. Observation among our German citizens will, we think, also bear this out: Falstaffian paunches being much more frequent among them than among the native-born. Hence it is that whilst in Germany magnificent institutions exist chiefly or solely devoted to the relief of excessive fatness, and "cures" manifold have wide-spread or local reputations, among the Anglo-Saxon millions Bantingism seems to be the only system which has reached the dignity of a baptismal name.

To discuss all the various German systems

in detail would be at present a wanton task, wasteful of the time of writer and reader, but some account of those at present most fashionable among our Teutonic brethren will, we think, be interesting to the readers of the THERAPEUTIC GAZETTE. Chief among these systems is that which is known as the "Oertelschen-Kur," or more commonly perhaps as the "Schweninger-Kur." It originated with Professor Oertel himself, who during his early childhood received a severe injury which led to sedentary habits, and finally, in 1875, to a condition of excessive corpulence, in which shortness of breath, marked failure of heart-power, complete inability to make any exertion, and increasing dropsy not only caused complete present disablement for work, but threatened eternal quiet in the near future. Medical treatment, mineral waters, baths, and all the efforts of the most renowned physicians of Munich had ended in failure. Finally, in despair, Professor Oertel devised and essayed the plan at present so much in vogue. By excessive exercise it was attempted to destroy the fat already accumulated, whilst by abstention from water and regulation of the diet the formation of new fat should be prevented. Further, it occurred to the sick man that heart and lungs were in a similar condition with the voluntary muscles, and that therefore cardiac and pulmonic gymnastics were as essential as was general physical labor. Any stout person who has climbed an Alpine steep on a hot August day knows full well the strain, the sweat out-pouring, the heart-thumpings, the breast-heavings which accompany such feats. And therefore to the mountains went our young physician, and after much labor and suffering he was rewarded by a regained health which soon led him to fame.

As is well known to our readers, Bantingism consists, in its essence, of the withdrawal of carbohydrates from the food and the living upon a more or less rigidly exclusive nitrogenous diet. If the views held by most modern physiological chemists be correct, that nitrogenous food is in part so split up in the system that fat is formed from it, it is plain that even by an exclusive nitrogenous diet we do not entirely cut off the supply of fat-material; and yet experience shows that in the great majority of cases under such restriction of diet the fat does disappear usually with great rapidity. The practical question is, however, whether the desired end is best obtained by such rigid dieting, and probably few practitioners who have thoroughly tried the plan

are entirely satisfied with it. It has been accused of producing Bright's disease, and it is certain that the excessive use of nitrogenous food does throw a strain upon the renal organs. The danger is, however, to our thinking, too remote to be of great practical importance, excepting in so far as it should lead the physician to occasionally examine the urine of the dieted patient, and if albumen should appear to change the treatment.

More valid objections are the chilliness and weakness, from which patients often suffer although the albuminous food is allowed in quantity, and the ever-increasing repugnance to meats, which in some cases becomes almost unconquerable. This chilliness and the longing for hydrocarbons seem to be based upon an actual need of the system for fresh hydrocarbon, and Professor Voit affirms that he has seen dogs fed upon an exclusively albuminous diet perish of inanition. Moreover, in some cases of Bantingism the stomach rebels altogether against flesh-digestion, and severe dyspeptic symptoms develop, whilst, if there be any tendency whatever to gout, arthritic symptoms rapidly become severe. As an exclusive, final method that devised by Dr. Harvey for the treatment of the corpulent Banting is, to put it mildly, not finally satisfactory.

A dietetic treatment of corpulence which has been much practised in Germany is that devised by Professor Ebstein, and generally known as the Ebstein method. It is simply a modification of the plan employed by Harvey. Three meals a day are allowed, the whole routine being as follows :

Breakfast.—Two hundred and fifty grammes of tea without sugar or milk ; fifty grammes of white bread, with much butter.

Lunch.—Fatty-soup, made from a marrow-bone ; one hundred and twenty to one hundred and eighty grammes of flesh, containing much fat ; some vegetables ; stewed fruit without sugar ; two or three glasses of wine. Later in afternoon, one cup of tea without milk or sugar.

Evening.—One cup of tea without milk or sugar, thirty grammes of bread and butter, one egg, or a piece of fat ham or fat roast meat, or cheese, and fresh fruit ; no alcohol.

As the result of living upon this diet, Ebstein, who was his own first patient, lost in the course of the year eighteen German pounds. He states that the use of the fat produced a sense of satiety, and stilled the thirst and carbon-longing, which are often so severe under Bantingism. The originality of the Ebstein cure seems to consist in the relief of

the hydrocarbon appetite by fat. It is largely employed in Germany, and has even been tried with asserted good results upon animals, especially upon the pug-dogs of the German dowagers. Vogel, in Stuttgart, is affirmed to have reduced a dog five hundred and eighty-five grammes in a week by administering daily three pounds of oatmeal, and at first one hundred grammes of fat, increased to one hundred and thirty grammes.

There can be no doubt that the rational treatment of acquired corpulence consists in the regulation of diet and exercise, and that it must be crowned with success if the plan be well devised and carefully carried out. The term *acquired* corpulence is used here advisedly, for there are certain families in which excessive fat-production is so constitutional that the most that can be done is to keep in check an inherited tendency.

The diet-problem when studied naturally divides into four parts : first, the quantity to be allowed ; second, relative amount of flesh, starches, hydrocarbon, and fats ; third, use of water ; fourth, use of alcohol.

Of these problems the last is so easily and plainly solved that it is well to get it out of the way immediately. Alcohol is never necessary to a well-fed, healthy man : it is a pure hydrocarbon, capable of saving fat. Its excessive use, especially in the form of beer, is a common cause of corpulence. Hence theoretically it should be denied entirely to the patient. If, however, the previous habits have been such that it is impossible to stop its use abruptly, it should be as rapidly withdrawn as can be done, and should when given never be in the form of a malt liquor, but of a light wine of such poor quality that the patient can be the more readily weaned from it.

In the great majority of cases it is excessive quantity rather than improper quality of food which causes corpulence, and reduction of the quantity is therefore the first aim of the practitioner. A little book published in England, which has hardly attracted the attention of the profession that it deserves, teaches just here a useful lesson. In this "Advice to Fat People" the anonymous captain of a British regiment states that for thirty-eight years he had been a martyr to obesity. At birth he "was an enormous freak of nature that was clearly intended for twins." At eighteen he weighed eighteen stone. Banting taught that "quantity may fairly be left to the natural appetite, provided the quality is rigidly adhered to." Our captain asserts that quantity is even more important than quality. In about ten months

he reduced his weight one hundred and seven pounds and his girth eighteen inches by closely adhering to the following dietary :

At 6 A.M., one pint of black coffee and one ounce of coarse brown bread or biscuit.

At 9 A.M., four ounces of lean meat, three ounces of brown bread or biscuit, and half a pint of coffee.

At 2 P.M., six ounces lean meat, three ounces brown bread or biscuit, six ounces green vegetables, and half a pint of any fluid, except ale, effervescing wines, or aerated water, followed by half a pint of coffee.

At 6 P.M., half a pint of coffee.

At supper, two ounces brown bread or biscuit, a couple of glasses of sherry or claret.

Our hero further affirms that fruit may be taken *ad libitum*, and that vegetables which grow above ground, such as cauliflowers (except peas, beans, and rice), are good, but those which grow below ground "are fat persons' poison." Liquorice powder is to be taken at bedtime *pro re nata*.

The average amount of food required by the human adult is generally acknowledged by competent authorities to be about as follows :

Albuminous materials.	Fat.	Starchy carbohydrates.
30 drachms.	25 drachms.	92 drachms.

The analysis of the ration allowed Mr. Banting, given by Dr. Carl Zahn, shows that he took daily

Albuminous material.	Fat.	Carbohydrates.
43 drachms.	2 drachms.	5.25 drachms.

whilst the Ebstein ration allowed contains

Albuminous material.	Fat.	Carbohydrates.
25.5 drachms.	21.25 drachms.	11.75 grammes.

It will at once be seen that the Ebstein ration furnishes much less of hydrocarbons to the system than is required for its support, and that the system is, as already stated, only a mild Bantingism. When it comes to the individual case of excessive corpulency, it is to our thinking very clear that no hard and fast rules, either as to diet or exercise, are allowable, but that each patient—his present, his past, his likes and dislikes, constitutional tendencies, etc.—must be carefully studied by the physician, and a special diet list and exercise programme be made out. General directions as to amount of food are sometimes sufficient, but usually will not suffice. To weigh the food and drink may be troublesome, but when the corpulency is very pronounced or very obstinate the scales are a necessity, and the daily ration must be accurately determined. Almost always it will be found that the patient has been eating far beyond the needs of the system. Care should be exercised in immediately reducing the amount, even entirely to the ration laid down as the average one. As the case progresses the standard should be departed from in the direction of increase or diminution, according to the individual needs. To our thinking it should approximate in character that of Ebstein rather than that of Harvey,—i.e., there should be only a moderate reduction of the fats and hydrocarbons below the norm, and only a moderate increase of the nitrogenous food. For the purpose of aiding our readers in arranging a diet list we append the following table, originally compiled by Dr. Zahn, which gives approximately the amount of food material in various common articles of diet :

Food.	Water.	Albumen.	Fat.	Carbohydrates.
Mean of ten different kinds of simple soup.....	91.	1.1	1.5	5.7
“ ten rich soups.....	83.2	2.6	3.2	9.7
Boiled beef, lean, from young heifer.....	66.5	28.4	1.3	
“ fat, “ “	49.	38.	12.1	
Beef, steers, and oxen, boiled.....	56.8	34.2	7.5	0.4
“ “ “ “ roasted.....	59.	38.2	1.7	
Roast meats, including beefsteak, game, birds, etc., reckoned as an average.....	58.	38.2	2.7	
Veal, roasted.....	78.	15.3	5.2

* Vegetables exclusively American, such as tomatoes and green corn, are not included in this analysis.

The question of the water allowance is a serious one. The chief hardship of the dieting is, to many Americans at least, the withdrawal of the water-supply, and patients continually ask whether water makes fat. So far as our present chemical knowledge goes, water does not make fat. Indeed, we have never seen a reason given, which to our own mind was satisfactory, for the abstinence from water-drinking that is so much insisted upon in all the modern systems of fat-reducing. The explanation offered by German writers is that by causing an increased blood-volume the water dilates the small capillaries and thereby facilitates the change of food-fat into body-fat. Whatever may be thought of this as science, the concord of practice is not to be forgotten, and, whilst the extreme measures in regard to the water ration seem unnecessary, it is probably in many cases essential to moderate the daily allowance.

When the symptoms of disturbance of the circulation are very great, and especially when the excessive drinking of beer or other liquid has caused a great excess in the bulk of blood in the body, abstinence from fluids may be imperative in order that the volume of the blood may be reduced and the strain upon the circulation lessened. In Professor Oertel's case the state of affairs just spoken of seems to have existed, and it is almost inevitable that he should magnify the importance of the dryness.

The choice of the form of exercise to be used in the treatment of a corpulent patient ought to largely depend upon the circumstances of the individual case. Two factors should never be lost sight of: first, the exercise should really be severe enough to be effective; secondly, it should be as little irk-

some as possible. There can be no disputing the severity and the effectiveness of mount-climbing as prescribed by Professor Oertel, and in Europe, with its great central mountain playground, mount-climbing is in a large majority of cases very practical. At first the patient may ascend the same slope day after day, each time going a little higher, but as "the cure" progresses different excursions should be made to add interest to labor. In America high attractive mountains are not so accessible as in Europe, and as we cannot believe that any one form of exercise has any specific or peculiar virtue, other work may be well substituted. Wood-sawing is largely employed in some European anti-fat sanitariums, and is undoubtedly efficient. Regulated severe gymnastic work is available in many cases. A form of foot-exercise whose fat-destroying value every trainer is familiar with is running. The influence which it has upon heart and lungs does not differ from that of mountain-climbing, and if there be any truth in the teachings of Oertel, as to the value of pulmonic and cardiac gymnastics, running ought to be of especial value when the heart or lungs are giving evidences of being especially affected by the fat-accumulation. Boat-rowing or even canoeing may serve the purpose of the fat man.

It seems to us, however, right here to give an especial caution in regard to any of these violent exercises,—namely, that at first they should be practised very carefully. They are of no use unless thoroughly performed, but may be taken slowly. The mountain-climber or the runner should at first stop every few feet, to allow heart and lungs to recover themselves. Moreover, in cases like that of Professor Oertel, in which the heart-symptoms are

severe, the physician must be very sure that the heart is not in a state of true fatty degeneration, but of fatty overloading,—*i.e.*, of what may be well termed fatty oppression. In a doubtful case the utmost caution must be exercised.

In directing the life of a corpulent patient the physician should always look after the details, such as bathing and clothing. The bath should always follow the exercise. Unless the latter is severe enough to cause free sweating it rarely will accomplish anything, and not only for cleanliness, but also for the purpose of keeping the skin healthy, washing is essential. The temperature of the water should be low, unless in very feeble patients or where the heart-failure is such as to create fear of shock. When the patient's means allow it, a half-hour's massage after the bath will not only be agreeable, but helpful. During exercise clothing should be sufficient to aid in sweating, but not oppressive. It is always necessary to guard against the possibility of taking cold during the exhaustion which at first may follow the exercise, but especially should patients who select mountain work be cautioned to protect themselves against the sudden weather changes which occur almost daily in such regions.

"A cure" which the writer can especially recommend to robust men who are fearing rather than suffering from excessive corpulence is a tour in the Rocky Mountains or in the wilderness of New Mexico or of Texas. If the expedition is arranged to be out six weeks, so that the only food carried can be flour, coffee, and salt-pork, and the daily horseback march or hunt is up to the full limit of equine and human endurance, there will be no need of a scientifically controlled dietary. The writer's experience in the Texan deserts—where the thermometer sometimes reaches 110° F. at midnight, water to be found only once in thirty-six hours, and shade at no time—leads him to especially commend it to the searcher after leanness who can stand the heat. More agreeable and scarcely less effective are the opportunities afforded in the higher and more northern table-lands and mountains of the Rocky Mountain region. Even in this cool atmosphere the writer has found that, although at first it may be a labor to climb upon the steed, at the end of six weeks of journeying the joints are loosened and an agility attained worthy of a cow-boy. The daily labor of travelling in a canoe in a wilderness such as that of Maine, the long hours of paddling or of rowing, the assistance to the

guides in camp-making, are in many cases sufficient to reduce the over-stout man to a better condition; and if he will shoulder his loads at portages manfully, carrying packs of forty or fifty pounds through swamp or forest, up-hill and down-hill for some hours daily, he will find little need to haunt sanitariums, but will soon gain back from nature that strength and freshness which, perchance, he has lost by unnatural eating, drinking, and physical indolence.

STENOCARPINE, THE NEW LOCAL ANÆSTHETIC.

THE evidence to which we referred in our August number as to the anæsthetic properties of the substance which is termed by Dr. Seward *Stenocarpine* has been confirmed by experiments made by Dr. Hermann Knapp (*Medical Record*, August 13, 1887) and Dr. Edward Jackson (*Medical News*, September 3, 1887).

Dr. Knapp's experiments as to the physiological action of this substance on the eye seem to prove that it produces anæsthesia of the cornea and conjunctiva in the same way and fully as energetically as a cocaine solution of equal strength. The conjunctiva becomes bleached and the seat of an unpleasant feeling of dryness, which sets in with the anæsthesia and lasts the whole day, while the pupil commences to dilate in from eight to twelve minutes, reaches its maximum, that of the utmost atropine dilatation, in twenty minutes, remains in this condition the whole day, and disappears, as a rule, on the fourth day. Accommodation likewise commences to diminish within ten minutes, and is completely paralyzed in twenty to twenty-five minutes, the tension of the eyeball being but slightly diminished, while the interior and mobility of the eye and the lustre of the cornea are unchanged. Dr. Jackson likewise found that instillation of one drop of a two per cent. solution of the drug caused slight smarting, followed by dryness of the conjunctiva and widening of the palpebral fissure; and within two and one-half minutes complete anæsthesia of the conjunctiva and cornea, the anæsthesia lasting for about twenty minutes. These results were obtained in sixteen different individuals, in all complete anæsthesia being attained in one or two minutes, and passing off mostly within half an hour.

It would also appear that it produces a wider dilatation of the pupil than other mydriatics.

Applied to the mucous membrane of the nose, throat, urethra, and glans penis and rectum, anæsthesia was readily produced to an equal if not more marked degree than can be obtained by the employment of a solution of cocaine of equal strength, while when applied to the throat or nose the senses of taste and smell are respectively suspended. Applied to the skin externally, Dr. Jackson states that it caused complete anæsthesia, his method being to simply moisten the surface and keep it continually moist with the solution, when, after about ten minutes, a needle might be plunged into the skin without the slightest sensation. In this respect Dr. Jackson's results are antagonistic to those of Dr. Knapp, who found that in five different cases external application to the healthy skin gave uniformly negative results. Dr. Jackson explains this discrepancy by attributing an extremely superficial action to the drug, and he states that it is only the external layers of integument which are anæsthetized, and if the point of a needle be plunged somewhat deeper it may be readily felt to pass from the anæsthetized layer into one in which it causes the usual amount of pain.

Dr. Jackson claims that to render this remedy applicable for producing painless operations on the healthy skin the incisions must pass but gradually through the skin, and that as each layer is divided the wound must be freshly moistened with the solution. In this way he claims to have succeeded in operating without producing any painful incisions.

As regards the toxicological action of this remedy when given in large doses, the nature of the symptoms of poisoning which it produces does not appear to be as yet clearly established. Thus Dr. Knapp states that its action is analogous to strychnine, five minims injected into a large rabbit causing violent tetanic convulsions, the pupils dilated, respiration and pulse accelerated; while Dr. Jackson, on the other hand, describes stenocarpine as a depresso-motor poison, and in no case in his experiments does he refer to the production of convulsions. In both cases, however, it appears that death is not produced through the action on the organs of circulation, since the heart continues to beat after entire cessation of respiration. It is evident that this part of the subject requires considerable revision.

As far as can be yet determined, the physiological action of this substance appears to be closely similar to that of cocaine, and would

suggest the similarity of action to that which might be possessed by a solution of cocaine containing one of the strong mydriatics, such as duboisine or hyoscyamine. For while cocaine has but little power of paralyzing the accommodation, and its action on the pupil may be overcome by one-fiftieth of its weight of eserine, stenocarpine requires two-thirds or four-fifths of the myotic to overcome it; and if, as evidence seems to indicate, it is as a local anæsthetic more powerful than cocaine, and as a mydriatic more powerful than homatropine, its future is a very promising one.

Unfortunately, the botanical origin of this drug is as yet unestablished, and the name stenocarpine therefore entirely unwarranted, as both Dr. Jackson and Dr. Knapp obtained their specimens from Dr. Seward, whose manufacture was also used in the experiments of Dr. Claiborne.

Dr. Jackson states that in Professor Charles S. Sargent's "Report on the Forests of North America" no such tree as the *Acacia stenocarpa* is mentioned, and although our inclinations would lead us to a warm reception of stenocarpine, our judgment leads us to hold our opinions in reserve until the source of the drug is clearly established, and until some other chemist succeeds in isolating an alkaloid with similar properties.

By this statement we do not wish to reflect on the methods or results of the gentlemen who have already experimented with this remedy; but we do not have to go into very ancient history to find an illustration of claims of a precisely similar nature which further experience proved to be entirely unwarranted, and attended only by the gravest disappointment.

Since writing the above Dr. J. H. Claiborne has announced in the *Medical Record* for October 1, 1887, that the substance termed stenocarpine is obtained from the *Gleditsia triacanthus*, and he therefore suggests the name of *gleditschine*. The methods of extraction of the alkaloid, if such it be, are not given.

VERATRUM VIRIDE IN THE TREATMENT OF PUERPERAL ECLAMPSIA.

ATTENTION has recently been called to the value of veratrum viride in the treatment of puerperal eclampsia. Dr. Ira E. Oatman, Sacramento, Cal., in a suggestive paper read before the Section on Obstetrics, Ninth International Medical Congress, says the remedy is "safe, speedy, reliable, and

permanent in its action." After controlling the convulsions by chloroform, morphine, chloral, and the bromides, and the evacuation of the uterine contents at the earliest possible period, he exhibits 8 drops of the saturated tincture *per os*, or 15 drops *per rectum*,—the dose to be repeated every fifteen or twenty minutes until the frequency of the pulse is reduced to forty beats per minute. When used hypodermically, he is of the opinion that the excessive action of the drug is less under control. At the same time the drug is administered it is well to have alcoholic stimulants at hand, although Dr. Oatman has never observed any toxic effects. He records a case of a man recovering after a dose of 120 drops of the saturated tincture, and of a child, 4 months old, after a dose of 52 drops.

At the twelfth annual meeting of the American Gynecological Society Dr. Charles Jewett, Brooklyn, read a paper, entitled "A Note on the Treatment of Puerperal Eclampsia," in which he recommends the use of *veratrum viride* hypodermically in doses of from 10 to 20 minims, repeated at the expiration of half an hour if the pulse does not diminish in frequency. "No convulsion can occur while the patient is under the influence of *veratrum viride*, and the pulse below sixty per minute." Dr. Jewett does not advise the use of the drug to the exclusion of all other remedial procedures.

The exhibition of *veratrum viride* in the treatment of puerperal eclampsia is by no means a new use of the drug. Fearn,* Boyd,† and Kenyon‡ have reported cases of puerperal convulsions in which *veratrum viride* was successfully employed. The evidence from clinical observation up to the present time, however, has been insufficient to establish the remedy in professional confidence, and we find no reference to the drug in the more recent European treatises on obstetrics.

A strong *à priori* argument in favor of this use of *veratrum viride* may be drawn from a brief consideration of the pathology of eclampsia and the physiological action of the drug. The very large majority of obstetricians will give assent to the proposition§ that puerperal eclampsia is a symptom of urinary resorption, conditioned upon functional or organic disease of the kidneys or mechanical

obstruction of the ureters,||—flexion, infraction, or stretching. The nerve-centres are poisoned by the retained urine, and increased reflex irritability results. The experiments of Kussmaul and Tenner render in a high degree probable the theory that the immediate cause of the convulsions, as in the case of epilepsy, is acute cerebral anæmia, the result of spasm of the arteries conveying blood to the brain. The convulsions and coma constitute a reflex vaso-motor neurosis. The peripheral irritant is very frequently uterine contractions.

Now, what is the physiological action of the remedy under consideration?

The numerous and exact researches of H. C. Wood have demonstrated that American hellebore is a powerful spinal and arterial depressant. "In full therapeutic doses," says Wood,¶ "it lowers the pulse-rate both by a direct action on the muscle (*jervia*) and by stimulating the inhibitory nerves (*veratroidia*); it diminishes the force of the heart-beat by a direct influence on the cardiac muscle (*jervia*), and produces a general vaso-motor paralysis (*jervia*) more or less complete according to the size of the dose." When a woman with puerperal eclampsia is under the influence of *veratrum viride* she is literally "bled into her own veins," while at the same time the activity of the spinal centres is also depressed.

Although a powerful remedy, American hellebore, as remarked by Wood, is probably the safest of all cardiac depressants. In the event of alarming symptoms resulting from the drug, it is a clinical fact that alcoholic stimulants are usually rapidly effective in the restoration of the functions of respiration and circulation.

In the light of the evidence now in our possession collected from clinical observation and experimental research, the drug is eminently worthy of further trial in the fulfilment of the indication just mentioned. While the remedy can have little or no effect upon the ultimate cause of puerperal eclampsia, and therefore ought never to be relied upon to the exclusion of other measures (the evacuation of the contents of the uterine cavity in particular), it is probably of very great value in maintaining the effect produced by chloroform, morphine, chloral, and the bromides.

The most eligible form for exhibition is

probably the fluid extract in doses of 3 drops. Norwood's tincture, a saturated spiritus, is more usually employed.

As a memento that the year is coming to an end, we have received from the well-known publishers, E. Blakiston, Son & Co., a copy of their visiting-list for 1888. As this is the thirty-seventh year of this publication, any extended notice of it would be of course superfluous. All the essential features seem to be reserved without much change.

C. E. DODSLEY affirms that the addition of four drops of the oil of sassafras to the ounce of iodoform completely does away with the disagreeable odor. This is certainly important, if true.

Reports on Therapeutic Progress.

TREATMENT OF FIBROID TUMORS OF THE UTERUS BY ELECTRICITY.

An interesting communication was made by DR. APOSTOLI (Paris) before the Section in Obstetric Medicine at the recent meeting of the British Medical Association (*Lancet*, August 13, 1887), with observations and complete statistics of all the cases so treated from July, 1882, to July, 1887, followed by a practical demonstration in the Rotunda Hospital by Dr. Apostoli himself. Owing to his inability to speak English, Dr. Apostoli's paper, which had been translated by his friend, Dr. Woodham Webb, was read by Dr. W. Duncan, one of the secretaries of the Obstetric Section. In this communication Dr. Apostoli says it is five years since he adopted a proceeding which he defines as a galvano-chemical cauterization of the uterus, vaginal, intra-uterine, or parenchymatous, and always monopolar. He points out that all the attempts made by his predecessors in the use of electricity were defective. The current of electricity was employed (1) in a vague and variable manner; (2) without dosage; (3) in a dose insignificant; (4) by a method always extra-uterine; and (5) by a method often dangerous. In 1882 Dr. Apostoli originated his new and rational way of using electricity, which he has since gone on modifying and improving. He claims to have supplanted the old method by a plan which is—1. Precise, by the introduction of new galvanome-

ters of intensity, exact counters and measures of the electric current. 2. Energetic. 3. Tolerable, in spite of the enormity of the doses, owing to the introduction of the wetted-clay electrode, which renders the cutaneous pole innocuous, and permits a current of signal medical intensity being transmitted through it easily and without injury. 4. Better localized. 5. Thoroughly under control. He applies to the diseased uterus a continuous galvanic current of an intensity and duration sufficient to produce the therapeutic effect required. This application is galvano-chemical cauterization. 6. More scientifically exact. The positive pole is hæmostatic—anti-hæmorrhagic—in its action, sometimes instantly, or, again, gradually; it is the remedy, *par excellence*, in bleeding myomas; on the other hand, with the negative pole we obtain a state of temporary congestion, without direct hæmostatic effect. It will render benefit in fibroids accompanied with amenorrhœa and dysmenorrhœa. He believes his method is—1. Easy of application. 2. Simple. It is a skilful uterine therapeutic soundage. It needs a good galvanometer of intensity, a battery capable of yielding an adequate current of electricity, an offensive cutaneous electrode in wet potter's earth, an inattackable intra-uterine electrode in platinum, and a steel trocar for the galvano-punctures. 3. The current is mathematically dosable. 4. The seat of operation is optional. 5. It is of easy control. 6. It is antiseptic. 7. It is easily borne, as a rule. 8. It does not impose on the patients any forced exclusion. The positive pole is the remedy for bleeding, the negative for non-bleeding fibroids; but, further, if the negative pole is made *by puncture* to enter into the substance of the fibroid, it will insure its diminution, and further, by a sort of *contre-coup*, will exert a hæmostatic action. Hence Dr. Apostoli gives these rules. Pole positive intra-uterine for the restraining of hemorrhage; pole negative intra-uterine for non-bleeding tumors; while the indications for galvano-puncture are twofold,—(1) as a matter of necessity, owing to uterine atresia, or where a sound, owing to displacement of the uterus, cannot be introduced; (2) by preference, if the punctures can be combined with intra-uterine cauterizations, so that one can expedite and make sure of effects which, with the cauterizations only, would be slower and more imperfect. Dr. Apostoli gives the following directions for galvano-puncture: 1. Antiseptic vaginal irrigation before and after each operation. 2. The puncturing instru-

ment should be a small steel trocar or needle, and the punctures should be shallow, not deeper than one to two centimetres. 3. The puncture should be made in the most prominent part of the fibroid, if possible in the posterior cul-de-sac. 4. No speculum should be used. 5. The seat of any pulsation should be ascertained, so as to avoid wounding any vessels. 6. If there is any unusual hemorrhage the vagina should be dilated with an expanding speculum, and, if necessary, pressure forceps should be put on the bleeding point. Dr. Apostoli claims that, as a result of this plan, every fibroid tumor will undergo a reduction appreciable by touch, and demonstrable by internal measurement. The reduction of the size of a tumor is generally associated with an accumulation of subcutaneous adipose tissue on the abdominal walls. Further, the regression of the tumor goes on after treatment has been suspended, it becomes liberated from its local attachments, and it tends to become more sub-peritoneal and pediculated. Again, from a clinical point of view, Dr. Apostoli asserts the results are not less striking. He says that ninety-five times out of a hundred all the miseries constituting the fibroidal condition are suppressed, such as hemorrhages, the troubles of menstruation, dysmenorrhœa, amenorrhœa, nervous disturbances, the direct pains in the growth itself, and from mechanical pressure and the harassing series of reflex actions. Dr. Apostoli has, in the five years from July, 1882, to July, 1887, made, either privately or at his clinique, as many as five thousand two hundred and one applications of continuous galvanic currents for most of the maladies included in the gynæcological nosology, which he thus enumerates in the following order: (1) Fibroids of the uterus,—polypi; (2) entire or partial hypertrophies of the uterus; (3) subinvolutions; (4) acute and chronic metritis and endometritis; (5) ulcerations of the neck of the uterus; (6) perituterine inflammations (perimetritis, parametritis, cellulitis, phlegmons); (7) ovarialgia; (8) ovaritis and periovaritis; (9) salpingitis; (10) ovarian and tubular cysts at an early age; (11) atresia; (12) hæmatocele. These five thousand two hundred and one operations (during a period of five years) were made upon four hundred and three patients. Of these he lost only two; in one he says he did not recognize the existence of a suppurating ovarian cyst which ended in death from peritonitis, in the other death was due to a puncture made too deeply. From July, 1882, to July, 1887, he has had under his care two hun-

dred and seventy-eight patients with fibroids or hypertrophy of the uterus in some manifest degree, upon whom he has used four thousand two hundred and forty-six applications of the continued current of electricity. He does not wish to convey the impression that all have been cured, but he affirms that when there has been no negligence, and where his advice has been fully acted on, ninety-five times out of one hundred permanent benefit has been acknowledged. Among the patients who had not the will to let Dr. Apostoli finish what he had begun, and whose impatience led them voluntarily to seek removal of their tumors by excision, seven put themselves into the hands of six most eminent surgeons, and not one recovered from the operation. It is of great importance that this new method of treatment should be brought before the notice of the profession, and hence a full *résumé* of Dr. Apostoli's paper is given.

EXPERIMENTS WITH ANTIFEBRIN.

According to the Vienna correspondent of the *Medical Press*, July 27, 1887, Dr. WEINSTEIN summarizes the results which he had obtained in his experiments with "antifebrin" in the clinics of the General Hospital in the following way: 1. As an antipyretic from $\frac{3}{8}$ to $\frac{1}{4}$ gramme dose is sufficient to lower the high temperature by three degrees after the lapse of from two to four hours. Antifebrin may be administered in daily doses of from 1 to 2 grammes. 2. The transition of the high temperature to the lower, and *vice versa*, is a gradual one. The apyrexia usually lasts for some hours, sometimes from twelve to sixteen. 3. No bad consequences supervene when the drug is administered with precaution. After large doses, such as 0.25 or 0.50 gramme, have been administered at one time, great perspiration, and occasionally also shivering or cyanosis, used to occur. Hyperpyrexia and collapses hardly ever supervened. 4. The blood-pressure first shows a tendency to increase, but is no longer influenced when the antifebrin has been administered for a longer interval of time. The rigidity of the blood-vessels increases slightly. 5. The best results were obtained with antifebrin in cases of erysipelas, puerperal process, and intermittent fever. The swelling of the spleen decreased. Dr. Weinstein remarks that antifebrin is best fitted for regulating the temperature, for producing a gradual decrease of the abnormal warmth of the blood, so that no

collapse may occur. He advises its administration in doses of from $\frac{1}{8}$ to $\frac{1}{4}$ of a gramme, from three to four times a day. The temperature must be measured twice daily, and the drug is to be administered only when the temperature has reached 40° C. and over. A decrease of 2° C. is sufficient. The administration of the antifebrin as an antirheumatic is to be recommended in acute cases, in doses of $\frac{1}{4}$ of a gramme at each two hours, and of from 1 to $1\frac{1}{2}$ grammes daily. The antifebrin may be administered in the same doses as a "nervinum," but only with a palliative effect.

THE INDICATIONS AND RATIONALE IN
WASHING OUT THE PUERPERAL
UTERUS.

DR. J. HALLIDAY CROOM recently read a paper before the Edinburgh Obstetrical Society in which he formulates the circumstances under which the antiseptic washing out of the uterine cavity is indicated (*Obstetric Gazette*, August, 1887).

Indications.—1. Where, with localized tenderness over the uterus, there is a high pulse and temperature, and a fetid discharge. It is to be observed that the discharge must be fetid *from the uterus*. In order to decide this question, it is essential to wash out the vagina with an antiseptic wash,—inodorous, such as corrosive sublimate,—and then putting the finger up and into the cervix, to decide whether it is fetid or not. As the author points out in the sequel, all first washings out should be performed under chloroform, therefore he always explores the cavity of the uterus with the finger. No reference need here be made as to the ease with which this can be performed, at least during the first week of the puerperium. Even at a long period after labor, the carbolized fingers can be comparatively easily introduced. In most cases some morbid product will be found, and in all cases the necessary dilatation of the cervix will much facilitate the process of washing out.

2. Where, with a high pulse and temperature, there is any question as to the absolute complete delivery of the placenta; and, in this connection, it is impossible to emphasize too strongly the importance of examining closely the placenta after delivery, whether it be expressed, extracted, or delivered spontaneously. Such care will often eliminate at once any possible cause of infection.

3. Where portions of membrane have been retained *in utero*, and give rise to increase in pulse and temperature. Here, however, it

should be noticed that it is possible to do harm in endeavoring to remove the membranes completely at the time of delivery. It is much better to leave a portion of membrane than to open up the genital canal in search for a small piece.

4. After the birth of a putrid foetus.

5. Where the uterus remains abnormally large after labor, and where, as a result, owing to the presence of decomposing clot, symptoms of septic infection develop themselves. In such cases, washing out ought to be accompanied by the introduction of the finger within the uterus, and in all such cases quinine ought to be administered in large doses.

6. In cases where, late on in the puerperium, symptoms of septicæmia develop themselves.

7. In those somewhat rare, but well-recognized cases, where, from acute flexion of the uterus, the lochia are retained and decompose.

8. In some cases of imperfect abortion and premature labor, and in all cases where the uterus, under such circumstances, has been curetted.

9. In all cases where the hand has been introduced—say in cases of post-partum hemorrhage, adherent placenta, or uterine hydatids—washing out the uterus with hot antiseptic water is the recognized treatment.

Rationale.—"What is the rationale," the author next asks, "of washing out the puerperal uterus in septicæmia?" It seems, at first sight, open to doubt how far washing out the uterine cavity can prove effective in checking septicæmia if rapidly-multiplying microbes have already passed into the system.

BALDNESS; WHAT CAN WE DO FOR IT?

The above was the title of a paper read by DR. G. T. JACKSON before the Medical Society of the County of New York at a recent meeting (*N. Y. Med. Journ.*, August 6, 1887). Alopecia præmatura alone received attention. Premature baldness, it might be said in a general way, was that occurring before the forty-fifth year, although the period was arbitrary. Subdivisions were made into idiopathic and symptomatic. The idiopathic form began unannounced by any antecedent disease. Many families had it for generations. The different causes alleged for it were named, but the author gave particular attention to the influence exerted by want of

proper care of the hair, as this was under the control of the patient, and was a part of prophylaxis and treatment. He was inclined to think that due attention to proper care of the scalp and general hygiene of the body were more reliable than any so-called remedies. Women gave more care to their scalps, and not only was baldness less common among them than among men, but the results of treatment were better. In families in which baldness was hereditary, prophylaxis should commence at birth with proper cleansing of the scalp, the use of soap and water, the brush and comb, and the avoidance of all things which might injure the scalp. The shampoo need not be repeated more than once or twice a week, and after drying some unguent, such as sweet oil, should be applied. What not to do was nearly as important as what to do. Pomades, as they were liable to become rancid and injure the scalp, should not be used. Wetting, twisting, pulling, and scorching the hair, as fashion demanded, were injurious. Close-fitting hats and caps should not be worn. Anxiety of mind should be combated by cultivating a cheerful disposition. Baldness due to dandruff, syphilis, typhoid fever, etc., next received attention. In addition to treatment appropriate to the special disease, the author again urged the importance of systematic care of the scalp and hair.

*A READY METHOD FOR REMOVING
FOREIGN BODIES FROM THE
ANTERIOR NARES.*

Physicians are often called upon to remove peas, buttons, and various substances from the nostrils of children who have themselves introduced them there. A ready method for removing such substances is described by Mr. T. OSBORNE-WALKER in the *Lancet* for September 17, 1887, where he states that recently a little boy was brought under his care with a button tightly impacted in the angle between the vomer and os nasi at the bridge in the right nostril. Ineffectual attempts at extraction had evidently been made, as shown by blood oozing from the nostril, and some, coagulated, adherent to the button, partially concealing its outlines from view, and also by the button being fixedly jammed in. In such cases, to prevent struggles and interruption, the child's arms, hands, and legs should be first confined, by folding tightly round these and the body a long, clean apron, and then placing the child on an attendant's lap, facing

a window, while the operator stands behind the patient, and, bending over and depressing with two fingers of the left hand the apex of the nose, to admit as much light as possible upon the object to be removed, with the right hand very carefully, to avoid its descent into the pharynx or larynx, the spoon end (with the concavity directed forward) of an ordinary pocket-case director should be introduced, with which at once with a simple lever movement or jerk the foreign body may be readily ejected.

By attention to the following points the removal is instantaneously effected: The close confinement of the hands, arms, and legs by a shawl, blanket, or apron; a good light; a reliable person to securely hold the child; the position of the operator behind the patient; depressing well the apex of the nose to obtain a good view of the object; and, lastly, getting the concave face of the spoon of a director fairly behind the body before making the forward lever movement.

*THE HYDRATE OF TURPINA IN THE
TREATMENT OF CATARRHS
AND BRONCHITIS.*

In the *Medical Record* for September 24, 1887, Dr. HALSTED BOYLAND calls attention to the use of hydrate of turpina, an alkaloid which has recently been discovered in turpentine. This substance consists of round, rhomboidal, and polygonal crystals, presenting much the same appearance as those of hydrate of chloral. Dr. Boyland administered it in a number of cases in the form of a mixture, finding that when given in pill form it was apt to cause disturbance of the stomach.

The following is his formula:

R Hydrate of turpina, gr. xxiv;
Glycerin, C. P., q. s. ut f. solutio;
Syrup of lactucarium, ad ℥i. M.

Sig.—Give 1 teaspoonful every three hours.

The employment of this remedy in the treatment of chronic catarrh causes loosening of the cough, renders the expectoration free and easy, the skin becomes soft, moist, and natural, and the bronchial râles diminish.

According to Dr. Boyland, there is not the slightest taste or odor of turpentine about this alkaloid. Taken in doses of 10 grains it produces in some patients a sense of fullness in the epigastrium and slight cerebral hyperæmia, accompanied by a feeling of stimulation. These symptoms disappear as the drug is withdrawn. 15 grains is a maximum dose.

HYDROCHLORATE OF APOMORPHINE.

This useful salt has been extensively tried by DR. STOCQUART, of Brussels, as a remedy for certain kinds of cough, and he speaks highly of its value. The kind of cough in which it has proved most successful is a distressing and frequent hacking unattended with expectoration, or with exceedingly difficult expectoration, and the improvement of the patient's condition is usually effected in a few days. The drug is, as a rule, well borne, although a few individuals manifest a special susceptibility to its action, and rarely nausea, colic, and diarrhoea result from its employment. The dose is a minute one, only 3 or 4 milligrammes of this alkaloid being given in water in the twenty-four hours; and, as the solution rapidly alters by keeping, it is advised to prevent its decomposition by the addition of a few drops of hydrochloric acid, which does not interfere with the therapeutic effects.—*The Lancet*, September 3, 1887.

A SIMPLE METHOD OF APPLYING FLUIDS TO THE NASAL CAVITY.

The general impression among the profession is that nasal douches are not only hurtful from the fact that possibly the fluid enters the Eustachian tube and there sets up inflammation of the middle ear, but it would also seem that the fluid itself in contact with the nasal mucous membrane may prove harmful. DR. CHARLES W. DULLES, in the *Medical and Surgical Reporter* for August 6, 1887, describes a simple plan for applying fluids to the nasal cavity, which is to be recommended on account of its feasibility, although we do not wish to be understood as recommending the method, when so many other appliances, such as the use of sprays, etc., are less open to objections. "Take a test-tube about four inches long and half an inch wide and place in it the solution to be used. Open the mouth and breathe through it. Put the open end of the tube into one nostril, catching the rim against the ala so as to make a good fit. Then bend the head back, and raise the closed end of the tube, so as to *pour* the fluid into the nostril. All the while keep breathing through the mouth. The fluid will now run into the nose, pass back to the naso-pharynx, and can be made to go around behind the septum and on top of the soft palate, and come out of the opposite nostril. By moving the head about in various directions the fluid can be made to reach any point in the nares, in front or behind, and to

remain in contact with it as long as may be desired.

"Any one who will try it will be surprised to find how thoroughly and easily this can be done.

"Of course, all fluid applications to the nares must be well warmed and of a proper specific gravity. If, for example, Dobell's solution be warmed to about 100° Fahr. and used in this way, it will be found a most soothing application. The quantity to be used may easily be as much as such a test-tube will contain. And it may be filled several times and used again and again at a single sitting."

TREATMENT OF SCARLET FEVER.

It would be interesting if a census were to be taken with a view to ascertain what treatment of scarlet fever was most in vogue among practitioners of to-day. We suspect that not an inconsiderable portion of this vote would fall to the lot of expectancy, by which must be understood the absence of any attempt to arrest the course of the malady, combined with great watchfulness of the symptoms and the treatment of the most dangerous of these morbid phenomena. The present epidemic (in London) is for the most part of a mild nature, but considerable attention has to be given to the throat, which seems to suffer in a marked degree, the glandular swelling being correspondingly marked. Hence it will be found that gargles of all kinds, and especially those of an antiseptic nature, are freely used, together with compresses of various degrees of heat and moisture applied to the neck. Most practitioners, even those of the most expectant schools, employ topical applications to the throat and nose. Many articles are used to relieve the thirst and sensation of dryness, but nothing is more effective than ice and a little raspberry vinegar. It is important to keep the nostrils and nasal passages sweet and clean. For cerebral symptoms, nothing is better than the application of cold, either in the mild form of lint soaked in iced water and applied to the shaven head, or in the more effective capilline tubes, with irrigation. Compression of the carotid arteries and bleeding are seldom practised nowadays, either in scarlet or any other fever. Aconite in minute doses, frequently repeated, is still the favorite drug of many practitioners, but its employment needs the exercise of clinical discretion, especially in children. Actual bathing in cool or tepid water is practised by but few physicians, though the number of practi-

tioners who recommend the use of cold or tepid sponging, the patient lying in bed on a mackintosh, appears to be largely on the increase. Most of the alleged specific and curative agents have long since lapsed into discredit. Belladonna finds but few adherents, and carbonate of ammonium almost none. Considerable difference of opinion exists on the merits of inunction with fat, cold cream, and the like, two of the most recent authors on the diseases of children taking opposite views, Dr. Goodhart advocating and Dr. Angel Money opposing the universal inunction, though the latter sees no objection to relieving the tension of the palms and soles by the application of geoline or vaseline scented with eucalyptol.—*The Lancet*, September 3, 1887.

THE THERAPEUTIC INDICATIONS FOR THE USE OF THEINE.

DR. THOMAS J. MAYS has shown that in theine we possess an agent which has the power of paralyzing sensation without affecting motion, and that it does this with a great degree of certainty, and without any appreciable injury to any part of the body, even when administered in large doses. He further shows in the *Polyclinic* for September, 1887, that in order to obtain the full effect of theine it is not necessary to inject it deeper than immediately beneath the skin, when it is exceedingly prompt in exerting its analgesic action. He has injected as much as $2\frac{1}{2}$ grains without experiencing anything but the best results, and he even would not hesitate to go beyond this limit. He has employed it in cases of neuralgia of both lumbo-sacral and cervical brachial surfaces, accompanied by sleeplessness, spasms of the muscles of both legs and those of the left arm. In these cases he gave $2\frac{1}{2}$ grains of theine subcutaneously in four different localities along the spine, which gave instantaneous relief to the pain and the induction of sleep during the following night. This amount was injected daily for twenty-one days in succession, at the end of which time pain had entirely disappeared and the appetite and sleeping greatly improved. In another case, of locomotor ataxia, 3 grains, injected in different spots along the spine, also produced great relief. No prolonged irritation and no inflammation are ever produced at the seat of injection, the slight burning which the injections produce being probably due to the large quantity of water which is required to dissolve this alkaloid.

Dr. Mays has found that benzoate of sodium increases its solubility, and he therefore uses the following formula :

R Theine,
Sodium benzoate, aa ʒi ;
Sodium chloride, gr. viii;
Distilled water, ʒʒi . M.

Sig.—For hypodermic use.

Six minims equal one-half grain of theine.

In the use of theine it must be borne in mind, first of all, that the property of this drug is simply to relieve pain, and while it performs this with perfect satisfaction, it will fail to give permanent relief in obstinate and protracted pain unless the cause of the pathological condition be combated.

THE TREATMENT OF SOME FORMS OF AORTIC DISEASE.

DR. SANSOM (London) gave a valuable address upon the "Treatment of Some Forms of Aortic Disease" before the Section of Pharmacology and Therapeutics at the recent meeting of the British Medical Association (*Lancet*, August 13, 1887). After a few remarks upon mitral disease, in which he said he had come to the conclusion that digitalis was our most efficient remedy in mitral regurgitation and convallaria in mitral stenosis, he gave an analysis of a large number of cases of aortic disease, from which he concluded that the two commonest causes of this form of cardiac affection were (a) rheumatism and (b) atheromatous degeneration. He had found these two causes about equally common. Aortic disease attained its maximum frequency in early adult life. In childhood, according to his observations, the mitral valve was affected in proportion to the aortic as 5 to 1. This accorded with general experience. He proposed to confine his remarks upon treatment strictly to one class of cases,—viz., aortic disease, arising from rheumatism; and he wished it to be distinctly understood that his observations did not refer to any other branch of the subject. He would divide rheumatic cases into two groups,—(a) those in which there were no symptoms referred to the heart, and (b) those cases in which symptoms referable to the heart were present. As regards the former class, patients sometimes sought advice for the most diverse maladies. He related a case of a lad who consulted him for incontinence of urine, and in whom well-marked aortic disease with hypertrophy of the left ventricle was found to be present. In

cases of aortic disease without cardiac symptoms, it might be laid down as an absolute rule that all agents which tended to increase the force of the ventricular systole were absolutely hurtful. Compensation being already perfect, such agents could only serve to disturb the equilibrium. Pain at the heart was an essential and early symptom in aortic disease, while it was well known that pain was not an essential symptom in mitral disease. The pain in aortic disease might attain the intensity of a true angina. Whether hypertrophy or dilatation should be the first to follow disease of the aortic valve was purely a question of nutrition. If nutrition were well maintained, hypertrophy would come first; if nutrition were imperfect, dilatation would precede. As regards the very important question of the administration of digitalis in aortic disease, medical opinion and experience had varied much from time to time. The present tendency was rather in favor of its administration, a view supported by so good an authority as Dr. Oliver, of Newcastle-on-Tyne. While carefully guarding himself against an absolute expression of opinion, Dr. Sansom pointed out certain drawbacks to the use of digitalis,—viz., (1) It may increase the distress and aggravate the symptoms present. In some of his cases where digitalis had had this effect he had seen great relief follow the administration of 5-minim doses of tincture of aconite and the inhalation of nitrite of amyl. (2) Digitalis sometimes caused sickness. (3) In some cases where much temporary relief was obtained by its administration sudden death had followed, apparently as the result of its use. Yet, in spite of these dangers and drawbacks, he believed that digitalis was sometimes of service in the *early* stage of aortic disease and for a *limited* time. If given in the same manner and for the same length of time as was usual in mitral disease, great evil would result.

THE MEDICINAL USES OF THYMOL.

DR. FREDERICK P. HENRY states in the *Medical News* for September 3, 1887, that he has been prescribing thymol in a number of cases of intestinal diseases, catarrhs, acute and chronic, and typhoid fever with satisfactory results, its employment being followed by steady decrease of the temperature, by gradual diminution of the daily number of stools, by the absence of mental excitement, and by

the clean, moist tongue presented in every instance.

The medicinal use of thymol is based upon its well-known antiseptic properties, and its action in the cases under consideration was favored by its great insolubility, which enables it to reach the intestine, mingle with its contents, and neutralize the toxic ptomaines that are formed in great quantity in catarrhs of the gastro-intestinal tract. In the opinion of many authorities, it is to the absorption of large quantities of these toxic products of fermentation and putrefaction that the so-called typhoid symptoms are largely due. These opinions do not rest solely upon theory, for it is found that, during the administration of thymol, phenol, which is one of the most constant products of intestinal putrefaction, and is almost entirely eliminated with the urine, is no longer found in that excretion.

Dr. Henry always prescribes the thymol in pill form, of which the best excipient is medicinal soap; a dose usually is a 2 to 2½ grain pill every six hours, and he thinks that, although this quantity may be increased with safety, the results obtained will be no better. In only one case, in which Dr. Henry's experience coincides with that of several other observers, was digestive disturbance occasioned.

INJECTIONS OF CARBOLIC ACID AND HYPEROSMIC ACID.

No one probably lays claim to a complete knowledge of the pathological changes which give rise to the condition or conditions known as muscular rheumatism, but it may fairly be supposed that they include a hyperæmic state of the perimysium, together with some plastic infiltration and migration of white blood-corpuscles. Now it was shown by Binz that carbolic acid, salicylic acid, and several other substances possess the property of paralyzing and killing leucocytes, and of preventing their migration. This led Dr. EDGAR KURZ, of Florence, some few years ago to employ intramuscular injections of a two per cent. solution of carbolic acid in a few cases of muscular rheumatism. The results were astonishingly satisfactory, and were published in *Memorabilien*, 1882, from which source a notice appeared in many other journals; not, however, always very correct as to the doses employed, grammes having been mistaken for grains,—a misconception which, however important, is often very difficult to avoid, as those who read many foreign medical journals know only too well, simply because abroad

"gr." sometimes stands for grains and sometimes for grammes, and as a gramme is more than fifteen grains, the consequences of a misunderstanding on this point may frequently prove serious. Dr. Kurz introduced from eight to forty syringefuls into the muscular tissue at a sitting, each syringeful consisting of a gramme of the solution. In no case was the urine discolored, or any other sign of toxic action observed; the injections were practically painless, and their anæsthetic effect became apparent in half an hour. Since these observations were published Dr. Kurz has continued to employ this method with excellent results. He has also found it very efficacious in the inflammatory affections of the sheaths of tendons due to injuries, and generally in sprains where the ligaments, tendons, or muscles were affected. Some similar and even more universally successful results have this year been published by PROFESSOR BENEDIKT, of Vienna, from the use of the same solution in affections of the ligaments and tendons, but more especially in acute rheumatism, where it appeared to act similarly to salicylate of sodium, quickly reducing the pain, the swelling, and the pyrexia. The best results were, however, obtained by combining the two methods, particularly at the commencement of the disease giving large doses of salicylate by the mouth and at the same time from one to three injections of carbolic acid daily. A somewhat similar form of treatment has been very successfully employed by DR. STEKOULIS, of Constantinople, in sciatica, an affection due to causes of very various nature, but frequently allied pretty closely with chronic rheumatic affections. The injection he used was a solution of hyperosmic acid, a substance which is in constant request by pathologists for hardening tissues for microscopical purposes. All the ten cases in which this remedy was employed were of considerable standing and very obstinate, Jacoby having recommended its use under such circumstances. A one per cent. solution was used, which, on account of the action of light upon it, was preserved in dark glass bottles. One gramme was injected deeply into the gluteal region close to the nerve, and this was followed by other injections extending along the course of the nerve to the number of something like a dozen. The pain caused by the injections was somewhat severe and burning, but it only lasted one or at most two minutes. At first the injections were repeated daily, afterwards every three or four days. Care was required

never to insert the needle into the same point as before. Out of ten cases, eight were completely and one partially cured, one only remaining unbenefited. No unpleasant effects beyond a slight tenderness over the points where the needle had entered, and which did not last more than a day or two, were observed.—*Lancet*, August 13, 1887.

THE CAUSES AND TREATMENT OF UTERINE DISPLACEMENT.

At the meeting of the Gynæcological Society held in New York DR. THOMAS ADDIS EMMET read a paper with the above title (*Medical Record*, September 24, 1887).

Close observation and a long experience, said the author of the paper, have been of but little avail, if it be true that the version of the uterus is the disease, and if a simple change in the extent of the deviation be the remedy for the displacement.

Moreover, his experience had taught him that the degree of prolapse below, or the elevation of the uterus above, *a certain plane* caused the symptoms now usually attributed to version alone. Years ago he had pointed out what he had termed "the health line," one that varies in each woman, but so long as the uterus occupies it circulation remains normal.

Anteversion of the uterus certainly is not an abnormal position. Retroversion, to a very marked degree, is frequently detected accidentally, not the least inconvenience ever having been produced by it.

The causes of displacements to which he directed special attention were the *external, and due to pelvic inflammations*.

There is a large class of cases which belong under this head, but which have not received the attention that their importance demands.

With a backward or a forward displacement, the only relief to be obtained must be through some means which will correct the prolapse sufficiently to restore the circulation.

When the uterus has been displaced in either direction, as the result of peritoneal inflammation situated on the anterior face of the broad ligaments, any attempt to correct the version will not succeed unless the same principle be kept in view. When the inflammation has been limited to one side, most frequently upon the left, it is equally impossible to devise any pessary which will not make direct pressure, and in time increase the difficulty by exciting a fresh attack of local peritonitis.

The question may be asked, "What is the general practitioner to do with such cases?" His answer would be,—if he is an honest man and considers the future well-being of his patient,—“Let such cases alone, so far as making any attempt to correct the displacement.” If it be absolutely necessary to undertake some mode of treatment, it should be confined to local application of iodine, with cotton and glycerin pads properly placed *to give needed support*, and to the use of hot-water vaginal injections. The treatment of such cases should never be attempted outside of a hospital service, and never would be were the consequences sufficiently understood.

Dr. Emmet then pointed out some of the peculiar features of the pelvic circulation of the female, its close relation to the surrounding fascia and connective tissue.

The whole skill in the successful application of a pessary is to so construct it that, while it relieves the prolapse, it will just dispose of the over-stretch. A pessary does not give relief by simply counteracting version. Its effect is an indirect one, because, when properly fitted, it diminishes congestion by correcting the prolapse and giving tone to the connective tissue of the pelvis. If a uterus, free from peritoneal adhesion, be replaced and a sufficient support to the fascia be again brought into play, it will then be retained in position through the natural elasticity of the surrounding tissues.

HÆMOPTYSIS TREATED BY INJECTIONS OF ERGOTIN.

M. GUELLIOT publishes in a Rheims medical journal some notes of a case in which he injected ergotin into the lung. The patient had been suffering for two years from daily hæmoptyses, which had been treated in various ways, but unsuccessfully. Subcrepitant râles could be heard in considerable numbers three fingers' breadth above the liver in front. The man had had pleurisy twenty-two years previously. His general appearance was good, and no tubercle-bacilli could be detected in the sputum. M. Guelliot determined to try the effect of injections of ergotin in glycerin into the affected region, employing the strictest antiseptic precautions. After a few drops of the solution had been injected the patient brought up sputum of a distinctly sweetish taste, showing that the injected liquid had been absorbed. The injections were continued, the quantity of liquid introduced

being gradually increased. The hæmoptysis began to diminish. The treatment had, after a time, to be stopped, as signs of bronchopneumonia developed. Ultimately the patient died. The base of the right lung was found to be in a state of gray hepatization, and there were pleuritic adhesions round all the lower half; also some tubercles at the apex. The interesting point about the case is the fact that after fifteen or twenty ergotin injections the hæmoptysis diminished in a remarkable degree.—*The Lancet*, September 3, 1887.

THE THERAPEUTIC VALUE OF SOME MEDICINES IN THE TREATMENT OF HEMORRHAGIC CONDITIONS OF THE UTERUS.

At the meeting of the American Gynecological Society, recently held in New York, DR. C. D. PALMER, of Cincinnati, read a paper with the above title (*Medical News*, September 24, 1887).

Referring to the fact that gynecology has assumed a decidedly surgical tendency, he said that too little attention has been paid to the less brilliant medicinal treatment. Uterine hemorrhage can often be treated advantageously by means of drugs, such as ergot, digitalis, cannabis indica, bromide of potassium, arsenic, and gallic acid. Ergot is especially useful in cases of chronic hyperæmia and subinvolution of the uterus, attended by menorrhagia, where the organ is soft and relaxed, and of interstitial and submucous fibroids. Hemorrhages due to fungous endometritis, ovarian and parametric inflammation are not favorably affected. Digitalis is useful in uterine hemorrhage due to cardiac disease.

Cannabis indica is an uncertain drug, acting rather upon the nervous system. Bromide of potassium is a sedative in ovarian irritation and congestion, and thus is useful in certain forms of menorrhagia, as well as in the treatment of hemorrhage from subacute and chronic pelvic peritonitis.

Arsenic acts by improving the general condition, and hence is of value in the menorrhagia of young women and at the climacteric, also in malarial conditions. He gave Fowler's solution in 3-minim doses. Active cathartics often exercise a favorable effect in checking uterine hemorrhage, especially if there is evidence of obstruction to the circulation from habitual constipation. In general, the administration of iron during the intermenstrual period is not advisable, unless the patient is markedly anæmic.

Hydrastis Canadensis has been highly recommended as a hæmostatic in uterine hemorrhage from any cause. Garrigues has obtained good results with *Gossypium herbaceum*, especially in cases of fibroid tumor. *Hamamelis* is inferior to ergot for the relief of sudden hemorrhage, but is useful in the treatment of long-continued flux, where the hemorrhage being of a passive character, the uterus is soft and flabby.

DR. FORDYCE BARKER said that he had found arsenic to be a valuable drug in the treatment of hemorrhages, of excessive flow at the time of the menopause, where vaso-motor irritability was especially prominent. It exerts a direct influence upon anæmia of vaso-motor origin. He is accustomed in treating such cases to administer full doses of the bromides during the time immediately preceding the flow, giving arsenic during the intermenstrual period.

Hydrastis Canadensis is of most value if given after the flow has begun. If there is marked vaso motor irritability he adds five or six minims of the tincture of *nux vomica*. *Viburnum* is a useful drug in menorrhagia and metrorrhagia, where the hemorrhage is of a passive character, especially in early pregnancy and in threatening abortion; it is a valuable uterine sedative.

He agreed with the author as to the importance of relieving the portal circulation, which was accomplished by the use of mercury and saline laxatives. In cases where the uterus was large and flabby, iron and opium should be administered during the intervals between periods.

THE TREATMENT OF GASTRALGIA.

SIR JAMES SAWYER states in the *Lancet* for August 13, 1887, that he has had remarkable success in the treatment of cases of gastralgia by the administration of $\frac{1}{4}$ of a grain of arsenious acid made into a pill, with 2 grains of extract of gentian, twice daily between meals. The use of this remedy must be continued for a few weeks, and, in cases of moderate severity, no other is necessary. The gastralgic pains become less frequent and less severe, and recovery is steadily and surely attained. In the severer cases he uses some form of counter-irritant to the epigastrium, usually employing a rubefacient. In severest cases, vesication by a fly-blister is of service, and the blistered surface should be kept raw for some days by the use of a daily dressing of savin ointment. In addition to

this medical treatment every hygienic adjuvant which tends to raise the strength of the patient is of value in the cure of gastralgia. When there is but little or no gastric catarrh the following dietary may be recommended:

Breakfast: bread and butter or dry toast, with some fresh white fish, or some cold chicken or game, or a mutton-chop, with a breakfastcupful of cocoa or weak tea or coffee. Dinner (1 P.M.): fresh beef or mutton, with bread, potatoes, cooked green vegetables, a fruit tart or a farinaceous pudding, with a glass of light bitter ale. Tea (at 5 P.M.): bread and butter or dry toast, with a small cupful of cocoa, tea, or milk and water. Supper (not later than 9 P.M.): white fish, or some cold chicken or game, or a little cold meat, with bread, and a glass of ale.

THE PUPIL AS A GUIDE IN THE ADMINISTRATION OF CHLOROFORM.

It is always difficult to determine the exact moment at which a patient is sufficiently under the influence of chloroform for an operation to be proceeded with. The sign of conjunctival reflex action, which is usually relied upon, is very variable and often misleading. MR. HENRY J. NELSON formulates the following conclusions as a guide in this respect (*British Medical Journal*, July 30, 1887):

1. The effect produced by chloroform on the pupil is at first dilatation, varying in degree and duration, then contraction as the narcosis becomes profound, and dilatation again when the sensibility is returning. If the administration be still continued, with the pupil strongly contracted and motionless, the pupil will also dilate, but in this case more suddenly and completely, and will be coincident with a state from which it will be difficult or impossible to resuscitate the patient. This latter is the dilatation of asphyxia.

2. So long as the pupil dilates in response to excitation by pinching, etc., the patient is not sufficiently narcotized for the operation to be proceeded with, unless the latter is slight and does not require complete anæsthesia.

3. When the pupil becomes strongly contracted and immobile, no more chloroform should be given until it begins to dilate again. If, then, further anæsthesia be required, a little more chloroform should be given till the pupil again contracts.

4. The occurrence of sickness causes dila-

tation similar to, but more sudden than, that which happens when sensibility is returning, and the efforts of vomiting have the effect of arousing the patient.

The watching of the respiration and the pulse, which are doubtless the best indications of the effect produced on the individual by chloroform, and, therefore, of vital importance for safe administration, does not in many cases furnish evidence of the state of sensibility, in regard to which he holds the observation of the pupil to be of greatest assistance. The sign usually relied on, namely, the insensibility of the conjunctiva, is by no means a satisfactory test, for in many cases conjunctival anæsthesia is established long before the patient can be said to be under the influence of the drug. By observing the pupil, the administrator of chloroform can tell at once when the effect of the drug is on the wane, because the pupil then begins to dilate slowly. Noticing this, he can, by the administration of a few drops more chloroform till the pupil contracts again, prevent the occurrence of struggling and interruption of the operation. In this way he can keep the patient in the state most suitable for the satisfactory performance of the operation without narcotizing him more than is necessary. The amount of chloroform required to maintain a state of anæsthesia is much less than that required to put a patient under its influence several times, and, as it is admittedly a dangerous drug, the less administered the better, especially in operations of long duration. And by allowing the patient partially to recover, one runs the risk of the occurrence of sickness and vomiting, which is always an awkward, and often a dangerous, accident. In the absence of such a guide as the observation of the pupil, the chloroform is likely to be given in a rather haphazard way, dosing the patient till narcosis is profound, perhaps too much so, then interrupting the operation till the danger is averted by arousing him, or waiting until signs of feeling, such as struggles or a cry of pain, give indication for more chloroform.

The observation of the pupil also furnishes a fair indication of the effect produced by chloroform; its size bearing a constant relation to the state of the blood-pressure. In the experiments on dogs the blood-pressure in the carotid artery was recorded on charts, and it was found that contraction only occurred when the pressure had fallen considerably, and, on removal of the chloroform, dilatation only took place when the pressure had risen to a certain height. As reduction

of the blood-pressure was pronounced by the committee of the British Medical Association to be one of the chief dangers in chloroform administration, the presence of a sign by which the occurrence of that important condition can be recognized must be of practical value.

SUTURE OF THE PATELLA.

MR. HECTOR CAMERON (Glasgow) read a paper before the Section in Surgery of the recent meeting of the British Medical Association, on "Suture of the Patella," with a new suggestion dealing with a shortened rectus muscle (*Lancet*, August 13, 1887). He believed that a permanently short ligamentous union was as good as union by bone. Almost all cases, however, where the union was a ligamentous one, were liable to tear. After wiring the patella he had his patients up in three weeks. He exposed the fragments, drilled opposite the centre of the fracture, used silver wire, twisted the ends and hammered them flat, and left them as a permanent clamp. Where the lower fracture was much smaller than the upper, he drilled from the lower surface. In his last three cases there was no drainage of the joint. Shortening of the rectus muscle very often occurred; and if there were any uniting bands he cut them away, and in extreme cases incised the muscle, as suggested by Mr. Rutherford. These incisions were two in number, oblique, but did not entirely divide the muscle, the portion left on one side being incised on the other.

DEATH FROM CHLOROFORM.

KAPPELER, in the *Archiv f. Klin. Chirurgie*, No. 35, 1887, discusses the question whether there is any connection between death from chloroform and the development of gas in the heart. Authors differ so widely upon this point that Kappeler was led to institute an experimental study of the subject, the results of which are as follows: He found that the development of gas in the heart is a frequent occurrence soon after death, and that it often cannot be traced to any visible decomposition. This phenomenon is not peculiar to the bodies of those dying from chloroform, but it may be the case, and this must be ascertained further, that it occurs more frequently with the bodies of those dying from chloroform than from other causes. Inasmuch as this gas is nitrogen, it seems natural to suppose that its production in the heart is

a post-mortem phenomenon, attendant upon decomposition. In chloroform-poisoning, inasmuch as we do not find this production of nitrogen gas during life in the tissues, it is probably a usual phenomenon of death, not dependent on chloroform.

THE THERAPEUTICS OF THE URIC ACID DIATHESIS.

The treatment of the uric acid diathesis was made the subject of discussion before the Section of Pharmacology and Therapeutics at the Dublin meeting of the British Medical Association. The subject was introduced by DR. BURNEY YEO in an address which commanded the attention of a large auditory for nearly an hour (*Lancet*, August 13, 1887). He said he would endeavor to confine himself to the practical aspects of the question. The pathology of the condition in which uric acid was present in excess in the organism was still doubtful. Murchison regarded the liver as primarily at fault, and with this view Professor Latham was disposed to concur. According to this theory, the essential condition present was the non-metabolism of glycosin into urea. Garrod, on the other hand, regarded the kidney as the active producer of uric acid. Ebstein placed its production in the muscles and marrow of bones. Frerichs held that the essential point was the perverted metabolism of albuminoid substances into urea. Bouchard denied that the presence of uric acid in excess was the chief feature in the morbid condition in question. One thing appeared certain,—that the uric acid diathesis had its foundation in the imperfect metabolism of food, especially albuminoids. He (Dr. Yeo) would define it as “mainly a disturbed retrograde metamorphosis.” Turning to therapeutics, he would point out that in all therapeutic questions three things had to be taken into account: 1, the pathogenic factor; 2, the constitutional factor; 3, the remedial factor. The two former were highly variable, and only the last had any claim to constancy. He would deal with the various remedies in detail. 1. Diet, regimen, and mode of life. There could be no doubt that, next to heredity, errors in eating and drinking were the most potent causes of the uric acid diathesis; but it was an error to assume that all gouty people had been intemperate. Ebstein regarded a tendency to obesity as a potent factor in the production of the condition, and advocated a dietary to check fat formation. He did not,

however, entirely exclude fatty matters from the dietary. He allowed cabbage, peas, etc., but no turnips. He (Dr. Yeo) thought that no good results followed from prohibiting the moderate use of animal food. Senator advises a minimum of fats, and especially prohibits the yolk of egg. As regards alcohol, he thought it would be better for some persons, especially women, to abstain altogether; in others a moderate use of alcohol was not objectionable. Malt liquors and bad wines were to be carefully avoided. He regarded the cheap clarets in common use as particularly injurious. He held strongly that the *quality* rather than the *kind* of wine was the really important point. As a general rule, those wines were best which had a diuretic action. A small quantity of alkaline water might be advantageously added to the wine. Still Moselle was good, and was now much used. Exercise in moderation was important as tending to improve the general health, but it must be borne in mind that gout was very common in those who took a great deal of exercise, and that women, who led comparatively inactive lives, suffered far less than men. A warm, dry, equable climate was useful. All climatic conditions which interfered with the action of the skin were hurtful. He advised the regular use of considerable quantities of water, preferably hot water. Turning to drugs, colchicum had been much assailed of late years, but he had never observed the ill effects which some authorities attributed to its use. Garrod, Sir Thomas Watson, and Graves had all borne witness to its value. He believed that its chief action was upon the liver. It had also sometimes a diuretic and diaphoretic action. As regarded the salicylates, he could not agree with Germain Sée that salicylate of sodium was the best remedy which we possessed. The benzoates had been highly recommended, but he was not convinced of their utility. Guaiacum, in spite of the high commendation of Garrod, seemed to be generally neglected. Iodide of potassium was very useful. Alkalies were in almost universal favor, but Dr. Latham did not think highly of them. There was a disposition at present to exalt unduly the merits of lithium, in comparison with sodium and potassium. He thought bicarbonate of potassium was the most certain diuretic of the group. Magnesia and lime had been largely lost sight of, but the success attending the administration of the waters of Contrexéville (which contained large quantities of these salts) should direct our attention to them. He thought Bath was likely to be as useful as

Contrexéville, and it was a much more attractive place. The mineral constituents of the waters at these two resorts were similar.

THE TREATMENT OF MORPHOMANIA.

BALL and JENNINGS, as an extension of the work already referred to in the *GAZETTE*, have observed in tracings taken of the pulse of morphomaniacs, when taken soon after an injection of morphine, that the curve greatly resembles that of chronic nephritis or aneurism of a large artery,—a moderately great line of ascent, a flat summit, and a slow descent. A few moments after the injection there was a rapid ascent, a sharp angle, and a rapid fall, with the normal secondary wave. These observations led the writers to question whether a cardiac stimulant would not prove useful in lessening the suffering of morphinism, and they seem in this supposition to have been correct. The remedy which they employed was sulphate of sparteine, which, in doses of from $\frac{1}{4}$ grain to $\frac{3}{4}$ grain, produced a most favorable effect upon the heart and also the general condition of the patient. An attempt was made to use nitro-glycerin, but it was too transient in its effects, and also gave rise to unpleasant after-effects.—*Bulletin de l'Acad.*, No. 17, 1887.

CHRONIC TOBACCO-POISONING; ITS INFLUENCE ON THE HEART AND STOMACH.

FAVARGER reports, in the *Wiener Med. Wochenschrift*, No. 37, 1887, the case of a man accustomed for a long time to smoke moderately, to whom he was called to relieve a severe asthmatic paroxysm, which left the patient suffering from difficult breathing and cyanosis. When the patient was first seen he was suffering severe dyspnoea, the sensorium was not clear, the pulse was very rapid (140 to 160 per minute). The axillary temperature was 95.6° F. and 96.5° F., the radial artery was contracted, the pulse small, and both pupils narrow and reacting very little. Obstinate constipation was present. On the twelfth day of the illness a laxative produced a normal stool. On the fourteenth day the patient passed blackish, altered blood; on the twenty-first day death occurred, with symptoms of internal hemorrhage. The autopsy showed dilatation and fatty degeneration of the heart, a chronic gastric ulcer at the pylorus, in which opened an artery, and hemorrhage in the entire intestinal tract as an im-

mediate cause of death. The patient was 60 years old. As nothing of sufficient severity to cause death was found in the body, it was considered a case of nicotine-poisoning, and the fatty degeneration of the heart was explained by the spasm of the coronary arteries produced by tobacco, producing ischæmia and fatty degeneration of the heart-muscle. The failure in circulation, following fatty degeneration of the heart, was especially predisposing to ecchymosis and erosion in the mucous membrane of the stomach, with the formation of ulcers. In addition to this it is probable that the saliva which was swallowed by the patient had a direct irritant effect upon the mucous membrane of the stomach, greatly predisposing to erosion and ulceration. Regarding the treatment of chronic tobacco-poisoning, in addition to the great point of abstinence, Favarger advises that smoking be never indulged in on an empty stomach. Inasmuch as nicotine has been found in perspiration and urine, he considers it not unreasonable that means to promote its elimination be used in treatment, such as baths, packs, diuretics, and diaphoretics.

MANAGEMENT OF ANTERIOR AND POSTERIOR DISPLACEMENTS OF THE UTERUS.

In opening the discussion on this subject before the Section in Obstetric Medicine at the Dublin meeting of the British Medical Association, DR. HALLIDAY CROOM (Edinburgh) said that he quite realized the responsibility he incurred in endeavoring to lay down definite lines of treatment in such a vexed question as that of anterior and posterior displacements of the uterus (*Lancet*, August 13, 1887). He divided them into two great classes,—(1) those occurring in nulliparous women; and (2) those occurring in parous women. In the first class he believed the displacements were entirely congenital, due either to non-development or deformity, and he strongly recommended that mechanical interference should, as a general rule, be avoided, both in anterior and posterior displacements. He believed that in the majority of cases they gave rise to no symptoms, and when symptoms of dysmenorrhœa or pelvic distress were present, concurrently with them these symptoms were due to some affection of the uterine annexa, for which mechanical treatment was utterly unavailing. He did not deny that in some exceptional cases mechanical treatment was

necessary, but these cases were so rare as not to affect the general fact. With regard to parous women, the case, he thought, was distinctly different. In many the symptoms arising from anterior displacements were due to some inflammatory process in or around the uterus, and the treatment should be directed to the removal of those inflammatory products, and not mechanically to the displacement of the uterus. With regard to posterior displacements in parous women, Dr. Croom thought that a distinction ought to be drawn. They, as a rule, were brought about mechanically, and, speaking generally, were the only forms of uterine displacement that required mechanical treatment. In the case of retroversion, if no adhesions were present, he believed that the uterus ought to be accurately replaced bimanually without the use of the sound, and retained in position by a Hodge pessary, or some other modification of that instrument. In retroflexion the Hodge pessary seemed to him inapplicable, and he believed that, as a rule, endeavors at replacement should be employed with care, and the uterus retained *in situ* with an ordinary ring pessary. In conclusion, he pointed out that there were some cases which required exceptional treatment, but in the main he advocated mechanical treatment for posterior flexions and versions only in parous women.

THE ELIMINATION OF IRON AFTER SUBCUTANEOUS AND INTRA- VENOUS INJECTIONS.

JACOBI made experiments bearing on this point by examining the urine of rabbits and dogs to which he had given iron subcutaneously or by intravenous injection. He used a preparation of iron not decomposed by albumen or alkalies, a form of the tartrate. On examining the urine qualitatively with ammonium sulphate he obtained only a negative result after injecting small doses subcutaneously. When the point of the syringe was introduced into a vein, the urine gave a reaction for iron at once. Jacobi studied the elimination of iron most carefully and accurately by removing the urine from the ureters by canulæ, which conducted the fluid into small glass vessels, which were changed every ten minutes, and which were tested by sulphate of ammonium. He demonstrated by this means the fact that after introducing iron into the blood it may be detected in the urine in twenty minutes, and that its elimination continues for three hours' time. An in-

crease in the quantity of urine excreted during the administration of iron was not observed. The quantitative estimation of the iron collected gave the result that the kidneys do not excrete more than from two per cent. to four per cent. of the quantity injected. A dog to which was given an equal quantity of nitrogenous matter and iron was found to excrete daily about 1.08 milligrammes ($\frac{1}{80}$ grain) of iron, which was determined by reducing from the ash of the urinary solids the iron with zinc, and treating it with permanganate of potassium. The same animal received iron by intravenous injection in three terminal subcutaneous veins in considerable quantities. The symptoms produced were tremors, movements of the head, loss of appetite, and lassitude. In twenty-four hours after the injection the elimination was ended. During the first day of injection the elimination was proportionate to the amount injected,—4.6 per cent. The iron injected was not given in one dose, but in several. On the third day a large dose of iron was injected, but only 1.4 per cent. was eliminated. By this was shown that the power of elimination possessed by the kidneys was very limited for any one call upon them; that the greater the number of divisions in which a given dose was given, the less the elimination became after each one. A certain amount of the iron was found to remain in the intestines of dogs, as has been observed in the case of bismuth.—*Schmidt's Jahrbuch.*, 215, 1887, No. 7.

THE PHYSIOLOGICAL ACTION OF ULEXINE.

PINET reports his researches on the action of this substance, as given in the *Archiv de Physiologie*, No. 19, 1887, as follows: He found this substance to be an alkaloid, soluble in water, crystalline, and bitter; it is derived from the seeds of the *Genista*. Repeating experiments which had been made upon frogs in England, he found that when put upon the tongues of frogs its action was to cause spasms, very much as cocaine sometimes does. In a few moments after the subcutaneous injection of $\frac{1}{40}$ of a grain of hydrochlorate of ulexine, he observed in frogs a period of disquiet, followed by convulsions, which resembled those caused by nicotine, and were elicited by disturbing the animal. Five minutes after the injection had been made, the animals became motionless, reflex motions ceased, and also respiratory move-

ments. The heart-beat persisted. After still five minutes no response was obtained on electric irritation of the central or peripheral ends of the ischiatic nerve; the heart beat feebly. After twenty-four hours there was no movement of any kind; the heart-beat was slow and weak; electric excitability of the muscles still persisted. Twenty-six hours after injection death occurred, the heart-beating is lost in attempted diastole. Other experiments resulted similarly. In studying the electric excitability, it was found that at first the excito-motor strength of the nervous centres and the nerves themselves were paralyzed. The substance influenced the nervous system and not the muscles, which could be made to contract by electric stimulation twenty-four hours after administration of the drug. Similar phenomena were also seen after the injection of ulexine when the spinal cord was severed below the medulla oblongata. Small doses, of $\frac{3}{40}$ of a grain, caused the same results, but in lesser degree, the posterior extremities being contracted in convulsions. Corneal reflexes were much lessened. Respiratory movements were very slow, but did not cease entirely; narcosis finally appeared, and, after twenty-six hours, the animal was perfectly well. Doses of $\frac{1}{10}$ of a grain produced similar phenomena, without convulsions. The writer had never seen the same effects from cocaine. In frogs, from which the cerebral hemispheres had been removed, the loss of consciousness came on more slowly, after forty or fifty minutes completely, perhaps because of a slower absorption of the poison on account of the shock produced. In guinea-pigs a subcutaneous injection of $\frac{3}{40}$ of a grain produced no effect; $\frac{1}{4}$ of a grain produced, after ten minutes, somnolence and delayed motion; $\frac{3}{40}$ of a grain, when injected into the abdominal cavity, caused death from peritonitis. In concluding his experiments the writer tested ulexine as an antidote for strychnine, giving a frog first $\frac{1}{1800}$ of a grain of strychnine, and then, after a few moments, $\frac{9}{20}$ to $\frac{3}{4}$ of a grain of ulexine. The result was that the ulexine not only prevented the onset of the strychnine convulsions, but had the power of checking them when they had broken out. This antagonism is only an apparent one, however, for, if the animals survive, in a few days complete insensibility and convulsions recur. Ulexine masks the action of strychnine for a time only. The reason for this is that the action of ulexine is much more rapid than that of strychnine.

PEAT MOSS AS A DEODORIZER.

DR. D. M. USPENSKI, in a preliminary note in the *Vratch*, describes a number of bacteriological and other observations he has made on a kind of peat moss belonging to the sphagni, which is indigenous in many parts of Russia and Siberia, and which is used with considerable success in the form of coarse powder for disinfecting cesspools and privies in Warsaw, Riga, and other towns. It is found that about four ounces sprinkled over an ordinary stool is sufficient to deodorize and dry it, so that the receptacle can be emptied and cleaned at proper intervals without any unpleasantness arising. This substance seems to have a wonderful power of absorbing moisture, for it was found by experiment that a pound of it which already contained twenty-five per cent. of water was capable of absorbing no less than seven pounds and a half more water. When added to fecal matter in the proportion of ten per cent. by weight, it changes it into an almost dry mass of an earthy appearance, devoid of smell and easy to remove. A hundred pounds of the powdered moss will absorb fourteen hundred and thirty-eight litres of ammonia. The dry mass obtained by the action of the moss on fæces, on being analyzed by Mr. Miltser, was found to contain from 2.38 to 2.66 per cent. of nitrogen and from 0.96 to 1.15 per cent. of phosphoric acid, and of course formed a very valuable manure. The powder as received contained 23.9 per cent. of water and 5.38 per cent. of ash, and without any preliminary drying they absorbed fourteen times their own weight of water. Bacteriological experiments proved that the moss has a great capacity for diminishing micro-organisms of various kinds. If this substance can be easily and cheaply obtained, it would appear to offer advantages over the dry earth we are accustomed to use, and in large towns would doubtless prove very valuable.—*Lancet*, September 10, 1887.

THE PHYSIOLOGICAL EFFECTS OF RED COLORING MATERIALS EMPLOYED IN COLORING FOOD-STUFFS.

ARLOING and CAZENEUVE have made experiments to ascertain the toxicity of coccelin and a Bordeaux-red, which are employed to color nitrogenized food-stuffs. The innocuousness of these substances may be inferred from the fact that as much as 18 grammes (3ivss) was injected into the blood of a dog without a fatal effect. The organs of cir-

culatation and respiration were, however, very greatly affected. The heart's action was much weakened, the small blood-vessels paralyzed, and the inspiratory movements almost abolished. First to fail was the vaso-motor system; then the respiratory apparatus and the heart were attacked. If still more of the substance was injected, death from heart-paralysis followed. An analysis of the gases contained in the blood showed the processes of oxidation after the injection into the blood but little affected. When these substances were fed to animals for a long time they were absolutely harmless. Post-mortem examination of animals which died after taking the substance showed in the internal organs nothing whatever abnormal. The use of these substances to color sweetmeats and liquors, and other allied food-stuffs, Arloing and Cazeneuve consider justifiable, while, on the contrary, other injurious coloring-matters are to be expressly forbidden.—*Bulletin de l'Académie*, No. 17, 1887.

A CASE OF EXTRA-UTERINE PREGNANCY CURED BY LAPAROTOMY.

SCHUSTLER reports, in the *Wiener Medicinische Wochenschrift*, No. 37, 1887, the case of a woman, aged 33, who was admitted into Von Dittel's clinic for the treatment of an abdominal tumor. She supposed herself pregnant, but all the usual signs of pregnancy were wanting. A diagnosis of a tumor proceeding from the internal genitalia, and probably a multilocular ovarian cyst, was made. When laparotomy was performed, the case was recognized as an extra-uterine pregnancy, whose sac contained a decomposed, fully-developed foetus. The mass was removed, the placenta not being recognizable. An attempt to remove the entire sac failed, on account of its connections with the abdominal viscera. Its walls were, however, stitched to the edges of the abdominal incision, and its cavity was filled with iodoform gauze, and a drainage-tube was brought out at the external wound. The further progress of the case was entirely favorable. The sac suppurated freely, and many pieces of necrotic tissue were discharged, which were thought to be pieces of placenta which had decomposed. The patient made a good recovery in about three months. The writer considers that the great danger which the presence of a dead and decomposed foetus, when developed outside the uterus, occasions to the pregnant woman, is full warrant for resorting

to laparotomy to remove the danger. This is especially true when the condition of the patient is so good as to lead to the hope that an operation will be successful, and when the condition of the case will not admit of delaying until the decomposition of the foetus and the peritonitis, which it occasions, have rendered an operation hopeless.

THE LOCAL TREATMENT OF AFFECTIONS OF THE BLADDER.

ULZMANN, of Vienna, critically reviews the use of the vesical douche, and reaches the following general conclusions and rules for practice. First, he excludes from treatment by the vesical douche all acute affections of the bladder: such diseases, if they heal at all, do so with dietetic and medicinal treatment. In chronic inflammations of the bladder we must discriminate whether the trouble is primary and isolated, or whether in addition to the bladder the vesical neck, posterior urethra, or prostate is affected. If the latter be the case, as in young men who from gonorrhoea contract chronic vesical catarrh, the neck of the bladder and the posterior urethra must be included in the treatment. This is best accomplished by introducing a soft catheter or small silver catheter in the bladder and then withdrawing it about an inch, so that the point of the catheter is in the neck of the bladder: with a small syringe the solution is slowly injected. The fluid enters the bladder but does not return into the catheter, as its fenestra is closed by the neck of the bladder. After all has been injected the catheter is withdrawn, and the patient empties the bladder spontaneously. If, on the other hand, the bladder itself is implicated, the fluid is injected through a catheter giving a double current and allowed to return. As the bladder is contracted, but a small portion of its mucous membrane will be reached by the fluid. It is best to inject the fluid through a soft catheter, using a syringe held in the hand. When irrigators are used too much fluid is introduced, and if the bladder is weak it may be dilated. Only in rare cases of contracted bladder in young persons is this method useful. The precaution must also be taken to empty the bladder thoroughly after each injection. When possible, it is best if the patient stand during the irrigation. For irritable bladder Ulzmann advises lukewarm water with tinct. opii, cocaine one-fourth per cent., resorcin one-half per cent., carbolic acid one-sixth per cent. when espe-

cially irritable. When the urine has undergone ammoniacal decomposition, solution of potassium permanganate one-tenth per cent. or three drops of amyl nitrite to a pint of water are recommended; for phosphaturia one-tenth per cent. salicylic acid is advised. —*Centralblatt für Chirurgie*, No. 30, 1887.

ABSENCE OF FREE HYDROCHLORIC ACID IN THE GASTRIC JUICE.

The diagnostic value of the absence of free hydrochloric acid in the gastric juice in cases of malignant disease of the stomach is discussed at some length in a recent paper by DR. V. G. NECHAJEFF, of St. Petersburg. For the detection of free hydrochloric acid no less than thirteen different tests have been proposed. Of these he considers the following to be the most useful: 1. A solution of tropeolin in water, as proposed by Edinger; this has of itself a yellow color, but when brought into contact with a solution containing 0.01 per cent. of HCl it becomes a dark cherry-red. 2. Methyl violet becomes blue on the addition of 0.025 per cent. of HCl. 3. Congo paper shows a blue tinge on being immersed in a solution containing 0.025 per cent. of HCl. 4. A mixture of three drops of liquor ferri perchloridi with the same quantity of carbolic acid in twenty cubic centimetres of water shows the presence of lactic acid or its salts by becoming yellow; but if free hydrochloric acid is also present the reagent becomes colorless. This is therefore an excellent test for free hydrochloric acid when lactic acid or the lactates are present. Dr. Nechaieff advises that all these tests should be applied in each case. He found that in cases of carcinoma of the stomach, and apparently in carcinoma of the œsophagus, absence of free hydrochloric acid constituted the rule, and its presence the exception, and is disposed, therefore, to think that its absence affords a practically useful diagnostic sign in cases where cancer of the stomach or œsophagus is suspected. Thus, in seven cases of carcinoma of the pylorus, though one hundred and forty-two examinations were made, free hydrochloric acid was never found, though lactic acid invariably existed; and again, in one hundred and five examinations of four patients with carcinomatous stricture of the œsophagus, no free hydrochloric acid could be detected. In a case of cancer of the rectum, however, the presence of free hydrochloric acid in the contents of the stomach was very distinct. —*The Lancet*, June 4, 1887.

THE TREATMENT OF ACNE.

BROCQ recommends as essential in the treatment of this disease the free use of hot water, alone or with camphor (alcoholic solution) or cologne. In addition he gives the following formulæ, which he has found of service in his own practice:

R Hydrarg. bichlorid., gr. xv;
Alcohol, ℥iiss to iii;
Aquæ rosæ, ℥ivss or iii.

This solution may be diluted as required by hot water. The following is an ointment used by Hebra:

R Sulphur. precipitat.,
Potass. bicarb.,
Glycerin,
Aquæ lauro-cerasi,
Spts. vin., aa ℥ii.

This is applied during the night; on the morning following it is removed by washing in warm water, and during the day a protective paste like the following is used:

R Zinc. oxid. pulver., gr. xxx;
Vaselin. pur., ℥vi¼.

At the hospital of St. Louis this sulphur paste is a favorite application:

R Sulphur. precipitat., ℥iii¼ to ℥viiss;
Alcohol. camphorat., ℥viiss;
Aquæ ros., ℥iii¼;
Aquæ destill., ℥iv¾.

This is also used at night, and an oxide of zinc ointment is used during the day. —*Revue Générale de Clinique et de Thérapeutique*, July 14, 1887.

ICHTHYOL IN SURGERY.

LORENZ, surgeon to the Alexander III. Uhlan Regiment, describes his studies with this substance in surgical practice, and their results, as follows in the *Deutsche Medizinische Zeitung*, No. 59, 1887. The writer has extended his use of this substance, and has treated not only superficial lesions, but also wounds and deeper losses of substance. As an important means of treating these cases he has used cold applications, in some cases an ice-bag, but generally cold compresses, which are changed every ten minutes if needed, and later every two hours. As a substitute for the cold compress, and an adjuvant; especially where an instantaneous use is needed, ammonium sulpho-ichthyolicum has been found to produce its effect more quickly and surely. Pain and swelling dis-

appear after one to three inunctions, and the patients can resume their journey when the condition of the lower limbs admits. The application of ichthyol allows the injured part to remain undisturbed, as it need not be renewed so often as compresses.

The mode of application is as follows: the limb is thoroughly cleansed with soap and water, and thoroughly and completely dried. Ichthyol in solution or in ointment is then rubbed in, but friction is not continued as long as with other ointments, as it is not necessary, and the limb is then bandaged with cotton fastened by an ordinary bandage. If it is impossible to first wash the part, the inunction with ichthyol may be done at once. These applications may be repeated two or three times daily, care being taken in removing the dried and accumulated ichthyol that the newly-formed cicatricial tissue may not be destroyed in cleansing the part. In comparing the length of time occupied in cures by ichthyol with that given up to hydrotherapy, ung. cinerea, and other commonly-used substances, it was found that the former needed only two-thirds of the time which the ordinary treatment required. Four cases are reported of serious lesions which were successfully treated. The first of these was a severe lacero-contused wound of the foot, to which ichthyol was applied ten hours after the injury was received. Four applications were enough to secure a cure; the swelling at the point of injury subsided entirely, and a slight weakness which supervened was gone in three or four days. A second case, of a serious wound of the hand, was relieved after six inunctions of ichthyol. A third case was that of an injury by a kick from a horse, producing a severe injury to the knee, which was treated at first by the application of cold and by rest. The knee did not improve, but became greatly swollen and very painful. Inunctions with ichthyol three times daily were made, and a series of measurements of the affected joint were taken. It was seen that a progressive diminution in size and sensitiveness followed. The treatment by ichthyol was alternated with hydrotherapy, with immobilization, with plaster of Paris bandages, and with electrical treatment. The final result was cessation of pain and cure by ankylosis. In wounds of minor character the following ointment has proved useful, either rubbed directly into the wound or laid upon it spread on bandage material:

R Ichthyol, 1 part;
Ung. paraffini, 70 parts.

In the excoriations common among children, and in all solutions of the continuity of the skin from which they often suffer, ichthyol is of great utility applied immediately after bathing. It causes at first a slightly burning sensation, but this is succeeded by cessation of all pain and irritation. It may be conveniently used in this ointment:

R Ichthyol, gr. iii;
Ung. paraffini, 3xxv;
Cumarini, gr. viii to gr. xv.

In burns and frost-bites a one per cent. salve of ichthyol and vaseline speedily relieves the burning pain and furthers cicatrization. In severe burns a watery solution, from two to ten per cent., is useful in allaying pain. In acute coryza, inflammations of all kinds upon the mucous membrane or skin of the nose, and in furuncles in the nostrils, a mixture of one to ten per cent. of ichthyol and vaseline may be applied, and gives great relief. In facial erysipelas the writer had the most satisfactory results with the continued use, at hourly intervals, of

Ichthyol, 3v;
Ether,
Glycerin, aa 3iiss;

which was applied with a camel's-hair pencil. While the remedy is not a specific, still it exercised a prompt and potent influence. Nussbaum reports five cases of erysipelas which were promptly cured by ichthyol and vaseline. There is as yet no ground for believing that ichthyol possesses antiseptic properties. If a wound be perfectly aseptic the application of pure ichthyol can introduce no element of danger, and will greatly hasten healing. It seems probable, however, that it may be combined with an antiseptic in such a manner as to be applicable to wounds as an immediate dressing. It would be an excellent prophylactic dressing against erysipelas, and in this respect an important field may be open for it. It should not be applied to wounds secreting freely with cotton, as the secretions of the wound become matted into the cotton, and drainage and disinfection are greatly hindered. It is best used in solution or in ointments, or, when indicated, in ichthyol plaster, the last but rarely. The preparation best adapted for general use is the combination of ichthyol with paraffine ointment, 1 to 70.

THE INFLUENCE OF MYDRIATICS AND MYOTICS UPON INTRAOCULAR TENSION IN NORMAL CONDITION.

STOCKER, in the *Archiv für Ophthal.*, xxxiii. 1, 1887, reports his recent observations with a manometer on the influence of the mydriatics and myotics in rabbits' eyes. His results differ from those given in text-books not only in the statement that the action of the pupil stands in a relation of cause and effect with the intraocular tension, but also that atropine increases the internal tension of the eye, that eserine lowers it, etc. His conclusions briefly stated are as follows:

1. Atropine, with animals curarized but not narcotized, slowly reduces intraocular tension (six millimetres).
2. Cocaine (two to three millimetres) lessens intraocular tension.
3. Both of these mydriatics do not influence the curvature of the cornea.
4. Eserine increases primarily the tension in an eye in physiological condition (three millimetres). Secondly, the tension is lessened: this secondary lessening is greater than the primary increase (four millimetres).
5. Pilocarpine increases considerably at first the intraocular tension; afterwards it is slowly lessened.
6. Both of these myotics shorten the corneal curvature.

THE TREATMENT OF PRURITUS OF THE VULVA.

DR. H. VON CAMPE, of Hanover, reports in the *Centralblatt für Gynäkologie*, No. 33, 1887, the following case, which illustrates the value of electricity in this most troublesome affection. Two years ago the patient, aged 53, came under the observation of the writer complaining of obstinate itching about the genitalia and anus. She had borne four children, and had aborted twice at three months. Some years previous the uterus had been curetted for disease of the endometrium, which caused frequent menorrhagia. Since this was done she had been annoyed by a persistent discharge, which had so irritated the parts that an eruption attended by intense itching had followed. The patient had tried all methods of treatment, even allowing the excision of a portion of mucous membrane which itched most severely, but without avail. When she came into the care of the writer she had not been treated for some time, having exhausted her resources and patience. Treatment by Unna's method, of salicylic-

acid salve and cocaine, gave only temporary relief. The vulva and adjacent parts remained a livid red, the elasticity of the skin was greatly diminished, and lesions caused by scratching were present. The discharge from the vagina was not great in quantity, and of a feeble acid reaction. The uterus was atrophic. The urine contained no sugar and no albumen. No signs of syphilis were present. The failure of other procedures led the writer to try electricity, and accordingly the galvanic current from six elements was used, the anode being placed in the vulva and the cathode upon diseased portions of the integument; the current was continuous. The applications lasted ten minutes. In addition, vaginal injections of weak, lukewarm carbolyzed solutions were made morning and evening. The result of the first application was cessation of the itching for several hours. The treatment was continued daily, intermitting at times, and increasing the number of elements to ten, for over a month, when the patient's condition was sufficiently good to warrant a cessation of the treatment. At this time only a sensation of slight itching and burning was present. The patient was able to sleep nearly all night, and to refrain from scratching and irritating the parts. The success in this case proved permanent after two years' time, and the writer felt himself justified in calling attention to this mode of treatment as one rational, uninjurious, and likely to prove of benefit in these intractable cases. It is at least worthy of a further and more extended trial.

ANTIFEBRIN IN THE TREATMENT OF LANCINATING PAIN.

FISCHER, of the Hospital for Nervous Diseases at Cannstatt, reports his observations in the use of antifebrin in the treatment of lancinating pain, in the *Münchener Medicinische Wochenschrift*, No. 23, 1887, as follows: Following the suggestion of Lépine, the writer treated ten cases of tabes dorsalis, on whom eighty or ninety observations were made. In general the results were most satisfactory, and corroborated the statements of Lépine fully. Among the ten patients the remedy failed in its effect only once; in the other cases its effects were prompt and powerful. Untoward effects in the eighty observations made for the relief of pain by antifebrin were present in only two instances, and these were exceptional among patients who formerly and afterwards were benefited by the drug. The writer felt justified in concluding that anti-

febrin is a specific remedy for the lancinating pains of tabes, whose effect, however, is not always uniform, nor constant, with the same patient at different times; the painful crises of tabes were generally favorably influenced by the drug. In long-continued use of the drug ill after-effects were not observed. A mild grade of cyanosis was observed in one case. All reported that very shortly after taking the remedy a pleasant, comfortable sensation of warmth pervaded the entire body. As many of the patients were ambulatory cases, it was impossible to make systematized observations on the pulse. The fact that the cases treated were not suffering from fever, and were without disease of the circulatory organs, explained the absence of ill after-effects with comparatively large doses. It is considered best to give to tabetic patients larger doses than would be indicated for those suffering from pyrexias: Lépine regards 30 grains as permissible. The effect of the drug was manifest, as a rule, from thirty to ninety minutes after the administration of the first dose ($\frac{3}{4}$ grain). If no effect follows this dose, a second small dose is given. The remedy resulted best in cases in which it was given to relieve a well-marked paroxysm. The results obtained in the treatment of neuralgias and migraine seem to indicate that all paroxysmal pain is especially susceptible to treatment by this remedy. Patients whose pains were like lightning from a clear sky, disappearing in a few moments as suddenly as they came, were not benefited by the drug: the point of influence for antifebrin seems to be wanting in these cases. The writer does not hesitate to use the remedy in broken doses in the treatment of chronic neuralgias, especially those of spinal origin, and the girdle sensation of tabes, especially as its effect is not lessened by an acquired tolerance. He gives his patients powders containing three and three-fourths grains, instructing them to take two powders when an attack of pain threatens, and, if needed, more. It is best to drink wine or cognac after the powder is taken. In other diseases characterized by paroxysmal pain, as in hemicrania, the drug has a positive influence. In addition to the treatment of tabes, the writer has given it as a nervous stimulant in fourteen cases. He obtained good results in (1) a case of syphilitic occipital neuralgia, which had resisted a persistent course of treatment by inunction. (2) In a case of specific dementia paralytica, with very severe nocturnal pains in the bones. (3) In three cases of headache

complicating severe anæmia. (4) In four cases of hemicrania or vaso-motor cephalalgia. In two of the cases typical migraine was present, and the patients, who were not hysterical, recognized the prodromata, and calculated the course of the attack sufficiently accurately to use the remedy as a prophylactic and also aborting remedy, with remarkably successful results. Negative results were obtained in five cases: 1. In a severe sciatica through disease of the veins; 2. In hysteria; 3. In dental neuralgia from caries; 4. In brachio-intercostal neuralgia in old men; 5. In a case of rheumatic neuralgia. Fischer repeats the account of Cahn's cases in the clinic at Strassburg. In two cases of gastric crises in tabes one was observed, after long-continued use of the drug in large doses, to suffer from cyanosis, and in the blood the presence of methæmoglobin. The urine contained an abundance of free SO_4H_2 . The blood-changes, however, occasioned the patient no inconvenience.

In a third case of gastric crisis the remedy had very little effect. Two cases of migraine were cured. A long series of headaches from various causes were promptly relieved by antifebrin. A good result was obtained in a phthisical patient who suffered from acute multiplex neuritis. In a case of obstinate pruritus, complicating carcinoma of the liver, the drug was useful in long-continued large doses. In pruritus senilis it had a limited value only.

*A CASE OF CHRONIC PERITONITIS
HEALED BY SPONTANEOUS
PERFORATION.*

HOCHHAUS reports in the *Deutsche Medicinische Wochenschrift*, No. 20, 1887, the following case: A little girl, $5\frac{1}{2}$ years old, had lost appetite for two months; digestion was painful, accompanied by regurgitation, and often by vomiting; the borders of the abdomen were sharply outlined; diarrhœa and constipation alternated. The child lost weight steadily, while the abdomen was excessively distended. On admission to the hospital, the abdomen was found painful on palpation; the percussion-note dulled to the umbilicus, and fluctuation evidently present. In the days immediately following admission intense fever, with evening exacerbations, vomiting, and diarrhœa, followed. A diagnosis of tubercular peritonitis was made. After several days the swelling evidently pointed near the

umbilicus; the abdomen retracted in several directions, the point of greatest prominence at the umbilicus became red, and changes in the areas of dulness indicated that perforation was imminent. Surgical intervention was abstained from, and about eight days after admission to the hospital perforation occurred, and the discharge of half a pint of purulent liquid. The opening was enlarged, an additional pint of pus evacuated, and drainage and an antiseptic dressing were instituted. The temperature fell at once; dulness disappeared, and cure followed. Such cases are extremely rare; but examples of cure after spontaneous rupture of the abdomen have been reported by Galvagni, Rehn, Bauer, Henoch, Leyden, and recently by Fiedler and Rossi.—*Revue Mensuelle des Maladies de l'Enfance*, September, 1887.

THE DIURETIC EFFECT OF SALICYLIC ACID.

The following is an abstract of a full paper on this subject by DR. ARMIN HUBER, of the medical clinic at Zürich, contained in the *Deutsches Archiv für Klinische Medizin*, Band 41, 1 u. 2 Heft. The diuretic effect of salicylic acid was noticed in Professor Eichhorst's clinic, where it was given for rheumatism, and where it is the custom of the clinic to observe the amount of urine passed by each patient. Fleischer, Baelz, Gubler, Robin, Sassitzky, Bauer, Künstte, Von Maurel, and Currier have observed and reported this property of the drug. The writer conducted a series of observations upon rheumatic patients who were taking salicylic acid. In twenty-five cases whose histories he carefully analyzed, twenty-one, or eighty-four per cent., showed an increase in the secretion of urine immediately on taking salicylic acid, which promptly ceased as soon as the drug was withheld. In four cases, or sixteen per cent., the diuresis continued during the days when no medicine was given. The drug was given in doses of from 45 grains to 2 drachms in twenty-four hours, and the connection between the drug and the diuresis was very evident. In a subsequent series of nineteen cases of pleurisy and other non-rheumatic affections, diuresis was increased in 89.41 per cent.; in 8.23 per cent. lessened; in 2.35 per cent. it was uninfluenced. The average increase in diuresis with those patients so affected was more than a pint. Regarding the influence of the remedy

upon losses by perspiration and expiration, in fourteen cases on whom such observations were made nine showed diminished loss by these avenues, while five lost more weight by perspiration and expiration on the days when no salicylic acid was taken. The total loss of weight from all causes was greatest under the use of the drug, and hence it is claimed as a diuretic. The doses were generally 15 grains hourly, beginning at 9 A.M.; 60 grains were often given in four doses each quarter of an hour. A series of observations on the effect of the remedy in typhus abdominalis showed that the quantity of urine was increased in 57.1 per cent. of the cases, lessened in 35.7 per cent., and uninfluenced in 7.1 per cent. A comparison of these results with the nineteen cases which preceded indicates that in typhus abdominalis the diuretic effect is much less than in other diseases: this result is not a lessening in the quantity of urine secreted, but the absence of the usual diuretic effect which follows the use of the remedy. In chronic pulmonary tuberculosis a series of five observations and twenty-three single tests showed an increased secretion of urine of 65.2 per cent. To determine the effect upon the solid constituents of the urine observations were made on cases of articular rheumatism, pleuritis, and typhus abdominalis, in nearly all of which the quantity of solid matter excreted was increased. In regard to the specific gravity, the increase in the amount of urine passed was attended by a lowering of the specific gravity. Observations made with Marey's sphygmograph upon those who were taking the salicylates showed that the pulse-rate was slowed during the use of the drug. In cases of pleuritic effusion the effect of the salicylic acid was especially marked as a useful diuretic, and the result obtained in lessening the exudate was so marked that its further use was indicated as a diuretic. In all conditions in which obstruction to the circulation exists the salicylates were found most efficacious. In connection with the treatment proposed by Oertel, in one case a gain of fifty per cent. in the quantity of urine passed was observed after the use of the remedy. It was found best to give it intermittingly, pausing for one or two days; and in this way on the day following administration the characteristic diuresis was produced. In combination with decreased consumption of fluid and other hygienic measures the administration of salicylates as diuretics promises results of value, and is certainly worthy a more extended and thorough trial as a diuretic.

COCAINE IN THE TREATMENT OF SKIN-DISEASES AND SYPHILIS.

DR. S. LUSTGARTEN, of Professor Kaposi's clinic in Vienna, writes as follows on this subject in the *Wiener Medicinische Wochenschrift*, No. 12, 1887: The effect of the external application of cocaine to the normal skin is almost nothing; but if the external horny layer is excessively thinned or removed, cocaine comes in contact with the nerves of the skin and produces its characteristic effects. From these facts he derives three indications for the use of cocaine:

1. In eczema. In this disease we can consider only the acute and subacute forms with abundant vesicular, strongly-itching pustules. In such cases the application of a two per cent. solution, once or twice in twenty-four hours, produces a great remission in the itching. An especially valuable part is given to cocaine in the treatment of eczema of the genitals and anal region where the epidermis has become macerated by long-continued perspiration and secretion. In such cases the subjective symptoms, itching, burning, etc., often reach a great degree of severity. Cocaine, with the employment of lukewarm sitz-baths and ablutions with pure soaps once daily, generally produces great relief. Lustgarten prescribes,—

R Cocaini aleinici, gr. vi to xv;
Lanolini, ʒiv ½;
Olei olivar., ℥xxx. M. f. ungt.

Sig.—To be rubbed thoroughly into the affected parts twice in twenty-four hours for several minutes; apply powder afterwards.

In pruritus ani, in addition to the above, suppositories of three-fourths of a grain of cocaine may be used with excellent effects.

2. Ordinary salves or lanolin ointments with one per cent. of cocaine are recommended in skin-diseases attended by considerable loss of substance with great pain. This treatment is especially useful in the effects produced by escharotics containing pyrogallic acid or arsenic, in gangrenous herpes zoster, etc.

3. In the form of a two per cent. watery solution frequently applied, the external use of cocaine muriate is very useful in rendering the application of nitrate of silver to granulations otherwise painful devoid of suffering. The granulations become pale very rapidly, and the silver nitrate when applied over them is not felt. In a great number of cases cocaine may also be used with advantage subcutaneously. An injection of the following solution has been found most useful:

R Cocain muriat., gr. viii;
Acid. carbol., gr. iii;
Aq. destill., ʒii ½,

and this may be given in several points into the rete mucosum, or may be given in one single injection. The addition of carbolic acid makes the cocaine solution permanent. In fifty cases so treated, on whom minor surgical operations were made (circumcision, extirpation of epithelioma of the lip, athe-roma, etc.), the results were most satisfactory. It may be useful in this connection to mention that two applications of this solution, applied by a brush, are sufficient to anæsthetize a circular area of two centimetres (about one-sixth of an inch) in diameter. A further occasion for the application of cocaine is to render painless the subcutaneous use of mercury and arsenic. This is especially applicable in the injection once weekly of calomel and tannate of mercury. To render this painless, half of the contents of an ordinary syringe is sufficient. After the cocaine injection has been made the canula remains *in situ*, and through this canula the calomel suspension is injected. When cocaine is added to the preparation of mercury before injection, the compound is decomposed. Although three-fourths of a grain of cocaine by subcutaneous injection is generally well borne, yet a sufficient number of cases in which untoward results followed have been observed to render the exercise of caution necessary. Lustgarten reports three cases in which after such injections very noticeable ill after-effects were observed.

ANTIFEBRIN AS A NERVINE.

According to the Paris correspondent of the *British Medical Journal*, August 20, 1887, at a recent meeting of the Société Vaudoise de Médecine, DR. PAUL DEMIÉVILLE, of Lausanne, read a paper on "Antifebrin as a Nervine Remedy." He had used the drug in eleven cases of sciatica, eight of lumbago, seven of intercostal and mammary neuralgia, eight of trigeminal neuralgia, eleven of headache (megrim, dyspeptic and chlorotic cephalalgia, etc.), three of neuralgia of the forearm and hand (probably identical with "ulnar neuralgia," described by Dr. McNaught, of Rossendale, in the *Journal* of April 30, 1887, p. 933), seven of painful menstruation, two of senile gangrene, three of tabes, six of epilepsy, cancer, nettle-rash, hepatic colic, etc. The remedy was given (in adults), as a rule,

in $\frac{1}{2}$ -gramme doses, from one to four times daily; if that failed, $\frac{3}{4}$ of a gramme, and even 1-gramme doses were given once, twice, or thrice a day. On the whole, Dr. Demiéville is satisfied that antifebrin is invaluable as an anodyne. In painful affections the drug scarcely ever fails to give marked relief, the pain disappearing within a period varying from a quarter of an hour to two hours. Its sedative action is very often accompanied by a decided hypnotic effect, which is extremely welcome in cases in which pain is associated with obstinate sleeplessness. In a certain proportion of cases the anodyne effects are only temporary. In other cases relief lasts for a more or less prolonged space of time, a new attack yielding to another course of the drug. But in many cases a complete cure is effected within a couple of days or so. As an anodyne, antifebrin is recommended by the author especially for the relief of the agonizing pain of senile gangrene and cancer. The drug seems to diminish the frequency of fits in epilepsy; at any rate, it had this effect in five out of six such cases in which it was tried by Dr. Demiéville. He recommends it also in hysterical fits and in infantile convulsions. When used for a considerable period, as, for instance, in incurable cases of organic disease, the drug loses its effect somewhat in time; on being discontinued, however, for some days, it seems to recover its activity. With regard to secondary effects, Dr. Demiéville states that he has never known it to produce rigors or noises in the ears; but he has sometimes observed diaphoresis and slight giddiness, and once (in a drunken epileptic, aged 51) delirium and hallucinations resembling those of salicylism. As a rule the drug is well borne by healthy digestive organs, but in certain cases of gastric disturbance it may give rise to temporary loss of appetite and dyspepsia, more rarely to nausea and vomiting, and possibly to diarrhœa. In one case lachrymation and a pricking sensation about the eyes were complained of after several 1-gramme doses had been taken.

ETIOLOGY OF DYSENTERY.

PROFESSOR JAROSLAV HLAVA, of Prague, has examined (*Pizeglad Lebarski*, February 12, 1887) the stools and the intestines, with their contents, in sixty fatal cases of epidemic dysentery, two of sporadic and ten in which the disease occurred as a complication of other affections. Recent stools from dysenteric patients were injected into the rectum or

duodenum in seventeen dogs, six cats, eight rabbits, and in hens and guinea-pigs. In addition to this, seventy injections of pure cultivations of various bacteria which had been found in stools and intestinal contents were made. From those extensive observations Professor Hlava was led to the following conclusions: 1. Bacteria are not the cause of dysentery, since the disease cannot be produced in animals by introducing into them any microbes found in persons suffering from the affection. A simple passing intestinal catarrh is all that can be induced in that manner. 2. The injection of stools gives rise to dysentery only in cats. 3. There is no specific anatomical difference between epidemic and sporadic dysentery. 4. There are present in the stools (and sometimes in the mucous and submucous coats of the bowel) long or oval amœbæ with a granular protoplasm, which move about under the objective glass for ten hours. In sixty-five cases the amœbæ were very numerous. Dr. Hlava is now studying the question of their relation to the disease.—*Brit. Med. Journ.*, August 20, 1887.

THE TREATMENT OF WHOOPING-COUGH WITH RESORCIN AND THE PNEUMATIC CABINET.

DR. ARNTZENIUS reports in a recent number of a Holland journal (*Weekbl. van het Nederl. Tijdschr. voor Geneesk.*, No. 67, 1887) his experience in the treatment of whooping-cough by resorcin. The number of remedies for this disease he admits to be legion; but, encouraged by the results obtained with this method by Moncarvo, of Rio de Janeiro, he undertook the treatment. He applied a watery one per cent. solution to the fauces and nares, and had excellent results in seventy cases. Arntzenius had been surprised that the use of compressed air and the pneumatic cabinet had not been combined with treatment by drugs. The reason was that in so few cases is a cabinet accessible. In eleven cases which he treated by the combined method, a cure followed after sixteen sittings. It was noticeable that after the first application the general condition was greatly improved, the anorexia was much lessened, sleep was more quiet, the paroxysms of coughing became less frequent and less severe. When a paroxysm occurred, the child's condition was soon restored again. All exhibition of drugs internally was discontinued during this treatment. The sequelæ which so often occur and are so injurious were never seen to follow

this treatment. The writer considers the influence of the compressed air, by reducing contraction by mechanical means, is more important than any effect on the micro-organisms of the disease.

ANTIFEBRIN.

DR. HERCZEL, of Heidelberg, writes as follows on this subject in the *Centralblatt für die Medicinischen Wissenschaften*, No. 30, 1887: The experiments of the writer have shown that the influence of antifebrin is not only upon temperature but also upon the circulation of the blood and the nervous system, and that it is in these directions that the evil effects of the drug are manifested when the dose is too high. It was found that rabbits behaved very differently to the same doses given hypodermically or by the gastric tube, and at different times. By the first experiments animals given doses of 15 to 25 grains showed little effect of the drug, probably because it was given on a full stomach. When the same dose was given in a warm watery solution subcutaneously, the symptoms produced were much more pronounced. It was found that antifebrin dissolved in the proportion of fifteen grains to two ounces of water at a temperature of 102.2° F.; and in twenty or thirty minutes after this quantity was injected under the skin of the back the reflexes of the lower extremities were impaired, tremors began which in the course of the next half-hour became periodic convulsive movements, which extended over the whole body. The blood-vessels of the ear were markedly contracted; the retinal vessels were not hyperæmic; the respiration was superficial and frequent. In ninety minutes after the intoxication was established all reflexes were abolished, the last being the corneal reflex. The bodily temperature sank, in spite of all possible means to maintain it, to 84° F.; respiratory movements only persisted. In spite of these profound disturbances the rabbit recovered in ten to twelve hours; the temperature remained several degrees below the normal for several days. If the subcutaneous dose was raised above 12 grains for each two and one-half pounds of body-weight, the reflexes were abolished in five or ten minutes. Respiration was at first very frequent, then irregular, superficial, at times ceasing entirely. Motor reflexes were entirely wanting; retention of urine occurred; in from sixty to ninety minutes coma, a marked fall of temperature, and general paralysis preceded death. Arti-

ficial respiration could not prevent the paralysis of the respiratory centre. Post-mortem examination showed the bladder distended with urine; the heart had ceased to beat in diastole. If the animals lived longer and continued to take the drug, fatty degeneration of the heart, liver, and kidneys occurred. Sections of the liver, treated by ammonium sulphate, or by ferrocyanide of potassium and hydrochloric acid, showed no reaction for iron.

The blood of the animals experimented on appeared, after one or two hours, to be greatly altered. Macroscopically it was reddish black; spectroscopically it gave a doubtful methæmoglobin line. With the symptoms which preceded death there went hand in hand a marked diminution in the oxygen of the blood. Under the microscope the red corpuscles were seen not in their usual *rouleaux* form, but thinned, somewhat granular, not adhering as normally. Their number was not greatly altered. The number of white corpuscles was somewhat reduced in the first stages of the effects of the drug; in the later stages increased. The hæmoglobin contained in the blood of animals experimented on was reduced from ten to eighteen per cent., and even more when the use of the drug was continued. In the blood of dogs especially, to which antifebrin was given continuously in large doses, a variable quantity of dissolved coloring-matter was found in the blood serum. A test of the reaction of the blood showed a diminution in its alkalescence. The first urine voided after the intoxication was established was acid, neutral, or rarely alkaline, dark brownish yellow, with a yellowish foam. In three cases a small amount of albumen, which could not be ascribed to the drug, was present. Teichmann's crystals were produced by salt and acetic acid, showing the presence of coloring-matter from the blood. Aniline and fuchsine tests were negative. Spectroscopic and chemical tests showed an abundance of bile coloring-matter. A minute quantity only of sugar was present. These experiments showed a profound alteration of the blood, which deranged the normal automatism of the medulla and depressed the functional activity of the spinal cord. The peripheral nerves were also affected, and aniline was doubtless separated in the organism. It is thus proven that the symptoms of aniline-poisoning and those of antifebrin (acetanilide) are identical, except in the fact that by the direct exhibition of large amounts of aniline a greater or less number of red corpuscles

are destroyed, while antifebrin produces much less alteration in the blood. Experiments have shown that an alkaline aniline solution of six-tenths per cent. destroys red blood-corpuscles in dilution of 1 to 7000 or 8000 blood, leaving only the stroma. An experiment upon an animal tetanized by strychnine showed the paralyzing power of aniline. Antifebrin produces no more marked convulsions, while aniline, in large doses, has this effect. Electrical examination of sensibility showed a less diminution after antifebrin than aniline, but the same effect produced by both. As an anodyne, the writer has used antifebrin in fifty-one cases, in thirty-nine of which satisfactory effects were produced; in twelve no result was obtained. In neuralgias of various nerves, central and peripheral, and produced by different causes, the results were excellent. Among the cases were four of facial, three of muscular, one of intercostal, and one of otalgic neuralgia. In severe pain produced by powerful irritation of sensitive nerves, as by cutaneous or subcutaneous inflammation (as ostitis, periostitis, operation wounds, caries, etc.), where the pain radiated in various directions, antifebrin was an excellent anodyne. In hemicrania and headache whose cause was intra-cranial, the drug was especially successful. This was seen in cases where bromides, caffeine, quinine, and antipyrin had failed of effect. In insomnia, general nervous irritation occurring after operations, or long continued, severely painful illness, antifebrin was an excellent sedative; its effect was to lessen markedly the general irritability of the nervous system. This influence was generally manifested in twenty or thirty minutes after taking the drug, sometimes in an hour: the duration of the effect varied according to circumstances. Individual idiosyncrasy was often observed; in anæmic persons the effects were produced by small doses. In giving the drug it is best to begin with small doses,—with women from 5 to 6 grains, with men from 6 to 8 grains, and repeat these doses in an hour. In anæmic patients not more than thirty to thirty-eight grains in twenty-four hours should be given, and the administration should be discontinued at intervals. In healthy individuals the effect of the drug is very marked. Its continued administration results in an aniline cachexia, and after continued administration for four or six weeks of thirty to forty-five grains daily the decomposition and dissolution of the coloring-matter of the blood was markedly felt. Aniline and its salts have a powerful effect upon temperature. In seven

cases of erysipelas, phlegmon, and septicæmia, with small doses, increasing to doses of 2 grains of aniline, a fall of temperature of from 2° to 3° C. was observed, and generally without cyanosis and other ill effects. As after antifebrin, the lowest temperature, pulse, and respiration rate was observed in three or four hours after administration, while the following rise of temperature, without chill, occurred in five or six hours. The doses which produced these effects in fever patients produced no effect on the temperature, pulse, or respiration of healthy persons. Sulphate of aniline and camphorated aniline also possess antipyretic power, and have also been used in doses of 3 and 4 grains in convulsions.

THE ACTION OF QUININE AND ALLIED SUBSTANCES ON CONTRACTILE TISSUE.

The following is a summary of an elaborate article with the above title, published by DR. R. B. WILD in the *British Medical Journal* for September 3, 1887:

Quinine acts essentially in the same manner on all forms of contractile tissue. In small doses it stimulates, as shown in the heart, the increased height of contraction of voluntary muscle, and the initial contraction of the vessels.

In larger doses, or after longer action of small doses, it completely paralyzes the contractile power of the tissue; this is seen in the arrest of amœboid movement, the cessation of response to stimuli in voluntary muscle, the stopping of the heart in diastole, and the dilatation of the vessels.

In very large doses, or after very prolonged action, quinine causes contractile tissues to pass into a state of rigor mortis, as shown by the small spherical condition of leucocytes, the rigidity of voluntary muscle, the contracted state of the heart, the secondary contraction of the vessels after long exposure to the poison, and the contracted state of the œsophagus.

Voluntary muscle (that is, the tissue in which contractility is developed to its greatest extent) was most susceptible to the action of quinine, and was thrown into rigor mortis by solutions which produce paralysis only of the less specialized tissues; with strong solutions (for example, 1 to 1000) voluntary muscle passes into rigor mortis so rapidly that the period of paralysis is abolished, and the tissue, after a short period of increased contraction, passes directly into a rigid and contracted condition.

Dr. Wild has found cinchonine to act like

weaker solutions of quinine; cinchonidine had a similar but more powerful action on voluntary muscle than quinine; quinidine, on the other hand, acted as a direct depressant, the muscle dying with great rapidity.

THE EARLY SIGNS OF LOCOMOTOR ATAXY.

DR. MAX KARGER has published as a graduation dissertation in the University of Berlin an account of a number of observations made on one hundred and seventeen cases of locomotor ataxy in Professor Mendel's clinic, with the view of detecting the early symptoms of this disease; for, as he says, the great hope of a really rational and satisfactory method of treatment lies in the recognition of the existence of the disease in its earliest stages. The history given by the patients established a connection between syphilis and locomotor ataxy in fifty-three per cent. of the cases. In the earlier stages he found symptoms affecting sensation, lancinating pains, numbness, especially of the lower extremities, cord-like sensation round the waist, retardation of the rate of conduction of sensations, and, what he looks upon as especially important, being almost always present, the so-called Romberg's symptom,—i.e., the inability or great difficulty of balancing the body when the feet are placed parallel and close together, the eyes being shut,—which, however, he does not consider is due to the ataxy, but thinks it is an abnormal condition of sensation. With regard to ophthalmic symptoms, he finds that at the commencement of locomotor ataxy there is a diminution in the acuteness of vision and a concentric contraction of the field, amblyopia and amaurosis, which were due in thirty-five per cent. of the cases to atrophy of the optic nerve. Then there were slight and transitory paralyses of the eye-muscles. Insensibility of the pupil to light was found in sixty-six per cent. of the cases, and was due sometimes to a paralyzed condition of the sphincter and sometimes to disturbances of reflex action. With reference to the patellar reflex, the author thinks it has been considered to be absent rather too universally. He found it in eight of his one hundred and seventeen cases. The bladder reflex was often diminished, so that chronic vesical disease, the cause of which is not to be made out, ought to lead a medical man to think of tabes. Impotence was much more common than any increased sexual reflex. Very rarely gastric and cephalic "crises" and joint-affections were noted.

The author suggests that complaints of a vague nature, such as nervous pains, eye- or bladder-troubles, should lead the physician to make a thorough examination with special reference to the want of patellar reflex, Romberg's symptom, and the want of reaction of the pupil, as these objective signs do not necessarily give rise to any subjective symptoms.—*Lancet*, August 20, 1887.

ANTIPYRIN IN LUMBAGO.

The Paris correspondent of the *British Medical Journal* for September 3, 1887, relates a remarkable case of cure of lumbago by subcutaneous injection of antipyrin, observed in a man, aged 42, a patient at the Hôtel Dieu. He could not sit down, and once in bed could not sit up. The lumbago was rheumatismal, for his fingers and toes were also swollen. After a first subcutaneous injection of 50 centigrammes ($7\frac{1}{2}$ grs.) of antipyrin, the lumbago completely disappeared. The injection of 50 centigrammes of antipyrin was continued every morning and evening, and at the same time 3 grammes (45 grs.) were administered by the stomach. The action upon the fingers and toes, although not immediate, was very rapid. The man is now perfectly cured.

THERAPEUTICAL VALUE OF THE MORE RECENT ADDITIONS TO THE GENITO-URINARY PHARMACOPŒIA.

MR. E. HURRY FENWICK gives the following summary of the action of a number of new drugs in the treatment of genito-urinary diseases (*Lancet*, September 24, 1887).

Kola (*Sterculia acuminata*).—A powerful stimulant; contains 2.3 per cent. of caffeine, also theobromine. In the form of chocolate this drug promises to be of great value in tertiary syphilis, where large doses of potassium iodide have to be administered. The cases of syphilis in which the chocolate was first tried were often of the worst and most neglected type, being drawn from the neighborhood of the London Docks. Later work has proved its value in the well-fed. Patients were able to take doses of 30 grains to 60 grains of the iodide without inconvenience as long as the kola was administered with it. It is now prepared in the form of a paste,—“kolatina,”—like cocoa paste, as it is found more effective in the liquid form. From 1 drachm to 2 drachms makes a breakfastcupful; where this is inconvenient, the stick

kola-chocolate is eaten. Dose, 1 drachm to 2 drachms.

Salix niger (Black Willow).—A sexual sedative of decided value; useful in ovarian hyperæsthesia, also in prostaticorrhœa, spermatorrhœa, excessive seminal emissions, and enforced continence. In the latter disorders its action is good, but inferior to potassium bromide. This is, however, somewhat counterbalanced by its non-depressant qualities. Dose, $\frac{1}{2}$ drachm to 1 drachm. Finding it of value in those wearisome cases of urethral neuralgias following gonorrhœa, Mr. Fenwick began to substitute sodium salicylate for it, and was impressed by the relief the latter afforded. In cases of urethral pain in the adult, he first eliminates stone, stricture, urethral granulations, and over-acid urine, and then prescribes sodium salicylate (5 grains to 8 grains), with a gratifying result.

Lycopodium clavatum.—The tincture is of real value in frequent micturition, irritable bladder, and cystospasmus, where such is not dependent upon actual disease or foreign body. It has been found useful in spasmodic retention of children. Dose, 15 minims to 1 drachm. Note: White lycopodium is an inferior substitute, but still of some value. Dose, $\frac{1}{2}$ drachm to 1 drachm, between bread and butter. Yellow lycopodium is useless.

Kava Kava (Piper methysticum).—This drug is of benefit in pyelitis, cystitis (acute or chronic), and urethritis. It is inferior to copaiba and sandal oil, but much more pleasant to take. It is of value when the oils are not tolerated. The inflammation seems to be increased at first. Fluid extract, $\frac{1}{2}$ drachm to 1 drachm on a full stomach.

Stigmata maidis (Corn Silk).—Difficult to obtain at certain seasons, but of great value in pyelitis and renal colic. One case is especially worthy of notice. A patient who had suffered from renal colic and pyelitis for seventeen years was admitted into the hospital for exploration of the kidney. The patient was so relieved with corn silk that he refused operative interference. It is also of value in chronic or subacute cystitis, but in the writer's hands it has failed in acute cystitis. Note: The fresh infusion is the best; dose, a wineglassful. Failing this, use the extract; dose, $\frac{1}{2}$ drachm to 1 drachm.

Papaw, Papyotin, Papaine (Carica papaya).—Of marked benefit in syphilitic ulcers of the tongue and throat, especially when mixed with cocaine. The surface of the ulcers and the white patches (secondary syphilis) rapidly clean and begin to skin over. Loz-

enges have been made which are most useful (papaine, $\frac{1}{8}$ gr.; cocaine, $\frac{1}{8}$ gr.; potass. bicarb., $\frac{1}{4}$ gr.). In a girl of 7, with severe syphilis of the mouth (after direct inoculation), the ulceration had resisted all applications for eight or nine months, and the child had wasted considerably. A few of these lozenges produced a marked effect, the ulcers healed, and the child rapidly fattened. Mix papaine with a small quantity of glycerin and water, so as to form a thin paste, add a little bicarbonate of potassium, and brush ulcers with the same thrice daily. Whatever its position may be as a digestive ferment, papaine is worthy of trial as a preventive and reducer (?) of renal calculi. Dose for renal stone, 1 grain to 3 grains, or more, in pill or powder; to be taken with meals.

Picht (Fabiana imbricata).—Of undoubted value in lithiasis and renal stone. One patient obtained so much relief from the hæmaturia and pain that he obtained the plant direct from Peru every mail, and made the infusion himself. In Mr. Fenwick's hands it has failed in chronic cystitis. Dose, fluid extract, $\frac{1}{2}$ drachm to 1 drachm; infusion, a wineglassful.

Cocaine.—The fresh work with this drug is to be brought before the Medical Society. Routine work: Lithotripsy in the feeble was performed with a four per cent. solution; small stones in the adult with a twenty per cent. solution. Internal urethrotomy needs a solution of twenty per cent., and any vesico-urethral instrumentation one of from four to twenty per cent.

Naphthaline (C₁₀H₈).—A derivative of benzol and allied to phenol. Given with benefit in fetid urine. The micrococci speedily disappear, and the urine becomes sweet. The large doses recommended (15 grains) are unnecessary, and produce vomiting and abdominal pain. Dose, 3 grains, cautiously increased. Note: Urine of patients taking naphthaline smells of phenol, and may remain exposed for some days without change.

Pine or Spruce Extract (Abies excelsa).—Has a slight diuretic action, and relieves renal pain unconnected with calculus. It is of use also in a bath, and as a liniment in gonorrhœal rheumatism. It is a pleasant vehicle for drugs in pyelitis and cystitis. Has proved of benefit in gleet. Dose, 1 drachm in water.

Ulexine (Ulex Europæus).—"A more powerful diuretic than sparteine or preparations of *Sarothamnus scoparius*" (Gerrard). This is to be employed with caution in stricture. One patient with stricture of old standing, after taking a pill containing $\frac{1}{16}$ grain, had

temporary suppression of urine, vomiting, and fever.

Strophanthus (Kombé).—Mr. Fenwick believes there is a distinct future before caffeine, digitaline, and strophanthus as adjuvants to operations upon the vesico-urethral tract. We have sometimes to deal with partial or complete temporary suppression, and sometimes with rigors after operative interference or even instrumentation. Caffeine seems indicated to avert the former; strophanthus the latter. Again, if we have reason to anticipate sudden flooding of the renal vessels, and consequent urinary fever as the result of an operation, then digitaline, from its power of controlling the renal circulation, is indicated. Our treatment, however, on these lines must go *pari passu* with our oncometric knowledge of drugs which affect the kidney circulation or the abdominal blood-pressure. The author believes strophanthus has power, worthy of further investigation, in controlling rigors. He employed it on the theoretical grounds that it increases cardiac power and general blood-pressure. Five in-patients, suffering from violent rigors after instrumentation, were treated with the tincture in doses of 5 minims after catheterization. In no instance were rigors induced.

Chaulmoogra Oil (Oleum gynocardiæ).—Of value as a liniment in gonorrhœal rheumatism, osteocopic pain of syphilis. Its power is increased if it is mixed with lanoline. It has great influence upon some forms of adenitis, also in secondary syphilis. Dose, 5 minims to 10 minims, on a full stomach.

Hydrastis Canadensis (Golden Seal).—Of some use as an astringent vesico-urethral injection, checking mucous discharge; worthy of trial in some forms of prostatic engorgement and enlargement. Dose, 10 minims.

Damiana (Turnera aphrodisiaca).—Good in some cases of diminished sexual power, where such does not depend upon organic disease. Often of use in melancholia and depression, if of genito-urinary origin.

Caroba (Jacaranda tomentosa).—Of some value in secondary and tertiary stages of syphilis. Dose, 1 drachm.

ANEMONIN.

Anemonin, the active principle of *Anemone pulsatilla*, is stated by M. P. VIGIER (*Journ. de Pharm.*, p. 99) not to possess the active properties of the fresh plant, which he believes are due to an essential oil, since the distilled water made from the fresh plant is extremely acrid,

causing symptoms of severe coryza, but in a short time becomes turbid, loses its acidity, and deposits anemonin. The anemonin, $C_{11}H_{11}O_6$, therefore, he believes to be formed by the oxidation of the essential oil. Anemonic acid, which contains one equivalent more of oxygen, is formed when anemonin is dissolved in an alkaline solution. It may be remarked that M. Vigier does not appear to be acquainted with the paper on this subject by Dr. Beckurts (*Pharm. Journ.*, 3, xvi. 365), in which the acidity of a freshly-prepared distillate is attributed to "anemone camphor," an unstable compound, which, in contact with water, undergoes decomposition into anemonin and anemonic acid. M. Vigier attributes the ready absorption of anemonin by the stomach to the fact that it is really soluble without alteration in hydrochloric acid (although it is rapidly destroyed by nitric and sulphuric acids). He does not think it is so poisonous as is generally supposed, having himself frequently taken 10 centigrammes without any poisonous effects. Yet, in doses of 2 to 4 centigrammes per day, its anti-catarrhal effects and its action on the nervous system are manifested. In consequence of the high price of anemonin he recommends the tincture of the fresh root to be used, made of equal weights of the fresh root and alcohol of ninety per cent., the dose being 2 to 4 grammes per day. If a tincture of the leaves be preferred, it is made of the same strength, but the leaves being less active than the root, the dose is given from 5 to 10 grammes daily. —*The Pharmaceutical Journal and Transactions*, August 27, 1887.

SCLEROSIS OF THE HEART.

According to HUCHARD the causes of sclerosis of the arteries of the heart may be divided into three groups: the first being due to intoxications, or rather toxæmia, by alcohol, tobacco, malaria, and lead; the second group is formed of causes such as the diathetic states of arthritism, gout, and syphilis; while the last group, and one to which exception may with at least some reason be taken, is composed of causes such as physical, moral, and intellectual over-pressure. The sclerosed heart may be either hypertrophied or dilated, but most often dilatation and hypertrophy are associated. Modifications of the form and size of the heart are the direct consequences of the initial vascular lesion and not of the ensuing sclerosis. The common lesion is obliterating arteritis of the

small coronary vessels, and it takes place slowly, so as to allow of time for compensating hypertrophy and for sclerotic lesions to develop. If the arteritis is of more rapid progress, dilatation of the heart and alterations of the heart-muscle fibres are the preponderant changes. Three histological varieties of cardiac sclerosis may be differentiated, following Weber: (1) peri-vascular sclerosis due to the propagation of inflammation; (2) the dystrophic sclerosis from regional ischæmia; and (3) mixed sclerosis. The changes in the muscle fibres are but imperfectly known. Two of the principal alterations are simple atrophy and the vitreous degeneration of Zenker. Nosographically, cardiac sclerosis is one of the anatomical expressions of arteriosclerosis of the heart. Weber regards arteriosclerosis as the outcome of certain etiological conditions, among which must be ranged heredity, certain hygienic habits, and various chronic intoxications.—*Lancet*, September 24, 1887.

ANDROMEDOTOXIN.

The investigation of Professor Plugge, to which reference has been made on more than one occasion, has shown that andromedotoxin is not only the toxic principle of the *Andromeda*s, but probably also of all the poisonous ericaceous plants. This compound has now been prepared in considerable quantity from the *Rhododendron ponticum* by HERR DE ZAAVER, who has further investigated its properties (*Chem. Zeit.*, July 31, p. 183). He reports that pure andromedotoxin occurs in white, delicate, crystalline needles, melting at 228° to 229° C., with signs of incipient decomposition, but bearing a temperature of 100° C. for a long time without alteration. The compound is soluble in alcohol, amylic alcohol, chloroform, ether, and benzol, and three times more soluble in cold than in boiling water. It shows the peculiarity that its solutions in water, alcohol, and amylic alcohol are lævogyre, whilst a chloroformic solution is dextrogyre. Andromedotoxin belongs to the class of indifferent bodies; its solutions in different liquids have an alkaline reaction, but it is not precipitated by any of the alkaloidal reagents, nor by the solutions of metallic salts, neither does it reduce Fehling's solution. Strong sulphuric acid gradually dissolves it with a brown color, but if heated on a water-bath with dilute sulphuric acid it assumes a beautiful rose color. Dilute hydrochloric and dilute phosphoric acid affect it similarly, the color being more violet-red with

the former, and mulberry-red with the latter; the reaction taking place in each case with a very minute quantity. The composition of the pure substance is most simply expressed by the formula $C_{61}H_{51}O_{10}$.—*The Pharmaceutical Journal and Transactions*, August 27, 1887.

THIRIAR ON WOUNDS OF THE PALMAR ARCHES.

DR. THIRIAR, taking as his text the case of a man who had been unsuccessfully treated both by a pharmacist and a surgeon for a wound in the hand, which, when he was brought into hospital, was both bleeding and suppurating, gave recently an instructive clinical lecture to the Brussels students on the management of wounds of the palmar arches. He pointed out that there is, from a clinical point of view, a distinction to be drawn between these and other wounds of the palm which implicate only the collateral branches, a distinction which is not clearly stated in surgical works which students read. The latter class of wounds present no difficulty, and the hemorrhage from them can be easily arrested. Not so, however, with the wounds of the palmar arches. Here, of course, the obvious indication is to search for the two ends and tie them. In consequence, however, of the tendency of the artery to retract, it is frequently impossible to find these ends without an amount of dissection which is undesirable. Perchloride of iron and other styptics hardly ever succeed, and they are to be avoided on account of the effect they produce on the surrounding tissues. The actual cautery is somewhat better, if not too highly heated, but even this very frequently fails. Even if success results, it is usually only temporary, for the muscular coat of the artery is apt, as Dolbeau pointed out, to relax after a time, and permit hemorrhage to break out afresh, in spite of any clots which may have formed. Similarly direct compression is seldom permanently successful. Compression of the ulnar and radial, forced flexion, and forced extension may be used as temporary expedients, for example, on the field of battle. Vanzetti's method of keeping the lips of the wound widely apart by means of hooks and that of forcipressure is not satisfactory, and Dr. Thiriard recommends that no time should be lost in trying cones of charpie and starch, elastic balls or sponges. The safest and best plan is to ligature in the wound if possible;

if not, above it. In recent cases it can usually be done in the wound. Where it is necessary to tie higher up, it is of no use to tie the ulnar and radial; and if the wound is not very recent, and there has been time for a considerable amount of collateral circulation to have developed, even the brachial must be tied above the profunda. It is necessary to remember that the axillary artery sometimes gives off two brachial branches as high as the axilla itself. M. Thiriar examined a large number of arms in the dead-house when he was in charge of the post-mortems, and found this anomaly present in twelve per cent. of the cases. However, he has always succeeded in arresting hemorrhage in wounds of the palmar arches, even when the tissues were suppurating, by a modification of Sir J. Simpson's plan of acupressure. He uses needles curved to a semicircle, and, passing them under the artery, brings the edges of the wound together and occludes the vessel by the application of a twisted suture, which there is no need to draw very tightly. He summarizes his advice thus: 1. Direct ligature. If impossible,—2. Twisted suture and acupressure. If unsuccessful,—3. Ligature of humeral in the middle, if the collateral circulation has not had time to develop; above the profunda if it has. 4. Employment of compression, direct or indirect, forced flexion, forcipressure, styptics, etc., only as temporary expedients.—*Lancet*, October 1, 1887.

AMMONIUM BORATE AND ZINC CYANIDE.

The latest remedy in vogue for the treatment of phthisis appears to be borate of ammonium, which has been found by PROFESSOR LASHKEVICH of great value, producing a marked effect on the expectoration, and in some cases diminishing pyrexia in the early stages of disease. The dose given was 5 grains three times a day, combined with codeine, henbane, or other sedatives.

The same authority has found in cyanide of zinc a remedy which exerts a beneficial effect on some cardiac cases, such as cannot be obtained by other means, particularly in cardiac neuroses, in which it acts quickly and certainly. Palpitation, want of rhythm, and pain in the region of the heart are quickly relieved and sometimes cured. The dose given varies from $\frac{1}{10}$ to $\frac{1}{2}$ of a grain three times a day.—*The Pharmaceutical Journal and Transactions*, August 27, 1887.

ETHER INHALATION IN TETANUS NEONATORUM.

DR. DEGHILAGE, of Mons, in Belgium, having a case of trismus neonatorum, and having repeatedly given chloral and ether per rectum without producing any effect, the child rapidly becoming worse and seeming in imminent danger of death by asphyxia, determined to administer ether by inhalation. In addition to this, artificial respiration was employed from time to time by means of a tube inserted into the nostrils. Some pieces of Rigollot's mustard-leaves were also applied to the chest. The child was laid on its side, according to a suggestion made by Marion Sims. The result of this treatment was that in a few hours the little patient's condition had improved to a very marked degree. The next day profuse perspiration occurred and the spasms entirely ceased. Shortly after this the child was convalescent.—*Lancet*, September 24, 1887.

TREATMENT OF GALL-STONES.

DR. SAMUEL MORALES PEREIRA, of Puebla, Mexico, gives an account in a Mexican medical journal of a case of "biliary calculus diathesis," with enlargement of the gall-bladder, in which he found a decoction of a well-known fern, *Asplenium ceterach* (or *doradilla*, as it is called in Spanish), of great value. The patient was a gentleman of good general constitution, who had suffered for a long time from pain of a more or less periodical character in the hepatic region. His digestion and his temper were considerably affected. He had applied to a number of medical men, but had never derived any benefit from their treatment. On examination the right hypochondrium was found to measure six centimetres more than the left, the region of the gall-bladder being distinctly enlarged and tender to the touch. The hepatic dulness in the axillary line was of normal breadth, but it extended five or six centimetres beyond the normal in a downward direction in the mammary line. On changing the patient's position, no alteration in the situation of this abnormal dulness could be detected. The patient, on being asked, said that his urine deposited a red sediment, and that he had at times passed calculi with his stools. Dr. Pereira, having had experience of the good effects of *ceterach* in gravel and urinary calculus, and believing that it exerts an influence

in "calculous diathesis," decided to employ it in this case. A decoction of half a drachm of the plant in five ounces of water was ordered four times a day. During the first twenty days no effect was observed. By the end of another twenty days the symptoms of mental irritability had disappeared, and the pain in the hepatic region had very greatly diminished. In fifteen days more the tumor in the region of the gall-bladder had become much less perceptible. The patient had been kept on milk and broth, which he did not at all like. He had passed three gall-stones and some gravelly matter with his stools, there having been some severe hepatic pain.

After this the patient continued to improve, though it was not easy to convince him that he was doing so. The amount of ceterach was diminished, and capsules of taurin prescribed, belladonna frictions being also applied to the hepatic region. He passed a succession of gall-stones, and the whole of the abnormal physical signs as well as the subjective symptoms passed away. Dr. Pereira hazards a suggestion that ceterach may have some effect on calculi already formed, as well as on the "calculous diathesis." He remembers being struck with the appearance of a stone—he does not say of what kind—which he saw removed from a young man's bladder, and which, though hard in some parts, was so friable in others that it could be broken down with the fingers. On questioning the patient, it was found that he had for some time taken ceterach by the advice of an old native medicine-man, and that while he was doing so he had remarked that he passed more urine, and that it contained gravel. The pain, however, did not diminish, and so he lost faith in the treatment and gave it up. It is to be remarked that the use of ceterach in urinary calculi is by no means new. Dr. Pereira does not explain what relationship he supposes to exist between the "calculous diathesis" which leads to urinary calculi and that which produces gall-stones, or why a remedy which is useful in one case should be prescribed in the other; still his facts, such as they are, are worth noting, and they seem to have interested the members of the Mexican Academy of Medicine, before whom they were brought, and who had the opportunity of examining the various gall-stones and gravelly matter passed with the fæces, as well as the partly friable vesical calculus upon which Dr. Pereira's suggestions were in part based.—*Lancet*, October 1, 1887.

COLD AFFUSION IN APPARENT DEATH FROM LIGHTNING.

DR. HIDALGO, of Mexico, brought before the Academy of Medicine of that city, at a recent meeting, the case of a man who was struck by lightning, and was at first thought to be dead, but who, after having had, at the suggestion of a passer-by, a large quantity of cold water thrown over him, began to show signs of vitality. He did not at first receive any medical treatment, so that the early history of the case had to be obtained from the relatives. After being brought home, water was still poured over him until he spoke for the first time, saying he was cold, and begging that this treatment might be stopped. He was then put to bed. During the night he did not sleep, but kept talking in a delirious manner, and complaining of pain, especially in the head. When asked what was the matter, he said at one time that he had something the matter with his chest, and at another that he had rheumatism all over, but he made no reference to the lightning. Dr. Hidalgo saw him the next day and found him in a semi-comatose state. The pulse was 75, full and compressible, the temperature normal, the respiration rather rapid. He was so deaf that he could only be made to open his eyes by shouting close to his ear. The pupils were contracted. He complained of pain all over, but especially in the head and arms. He had passed three badly-smelling liquid stools during the night. He was neither hungry nor thirsty. The electric spark had entered the upper part of the right parietal region just behind the auricle. The scalp was burned over a surface of about four by five centimetres, and a spot of dried blood was seen on the upper part of the auricle. The right side of the neck was reddened as by a burn of the first degree; below this, as far as the umbilicus, the effects were equal to those of a burn of the second degree, of the width of about fifteen centimetres at most, but very irregular in its dimensions. The electric fluid had passed down the inner aspect of the right leg, producing a burn of the second degree. It had then passed down to the foot, where the burn was of the first degree, and the strip of skin affected much narrower than above. The hat, coat, and trousers were injured—as if torn—all along the course of the current, but they were not burnt in any part. The patient was treated with sedatives and some clysters, and in sixteen days was perfectly well. Dr. Hidalgo supposes that the pneumogastric was affected by the shock, which paralyzed the respiration, and subse-

quently the heart's action, similarly to the behavior of an overdose of chloroform. The indication, therefore, was to re-establish the respiration, and this was admirably fulfilled by the cold affusion, which fortunately was administered quickly, before the paralysis of the heart had become absolute.—*Lancet*, October 1, 1887.

THE USE OF SALICYLIC ACID IN THE TREATMENT OF SCURVY.

MR. ALEXANDER FAULKNER calls attention, in the *Indian Medical Gazette* for July, 1887, to the efficacy of salicylic acid in the treatment of scurvy, stating that the advantages which resulted from its administration have been so marked as to warrant the hope that others would give this drug a fair trial. In no case in which he employed it were any untoward consequences noted, though the cases in which it was used were free from any renal or hepatic complications,—conditions which, if present, are supposed to be indications for the non-administration of the drug. As the elimination is not rapid, and congestion of the kidney or liver certainly in a great measure retards its excretion, it is evident that caution must be observed in prescribing this drug, and it should not be given in any case suffering from renal or hepatic complications. As a preliminary precaution Mr. Faulkner recommends the analysis of the urine and the avoidance of the use of this drug in the aged or the very young. He reports a case of scurvy in which this treatment was used with success.

CARBOLIZED OIL IN SCARLET FEVER.

In a paper by MR. JOHN BROWN, medical officer of health of the borough of Bacup, testimony is borne as to the prophylactic advantages attending the early and continued inunction of carbolized oil in cases of scarlet fever. The carbolized oil used contains five per cent. of the pure carbolic acid, and, as soon as the rash is out, this is applied over the whole body except the face, for which olive oil is used. The inunction is repeated twice a day, with a warm bath every night, and the treatment is continued until the sixth week, by which time it may be expected that the desquamation of the skin is complete, and the patient therefore no longer capable of conveying the infection.—*The Pharmaceutical Journal and Transactions*, August 27, 1887.

Reviews.

SPINAL IRRITATION (POSTERIOR SPINAL ANÆMIA).

By William A. Hammond, M.D.

Detroit, Mich.: Geo. S. Davis, 1886.

Every practitioner in American cities must have seen large numbers of instances of that group of medical cases which form the subject of the little brochure before us. The acknowledgment of the existence of this class of cases does not, however, of necessity involve the recognition of spinal irritation so called as a distinct disease; and the assertion of Dr. Hammond on page 19 must be set down to ill nature or lack of tolerance rather than to inherent truthfulness. Such persons must necessarily belong to one or the other of the following categories: their experience must have been very limited, and therefore they cannot see, or they must have been endowed either with restricted powers of observation or with minds so constituted as to cause them wilfully to close their eyes to the facts that they did not care to see. The question is, whether this so-called disease is not simply a form of hysterical disorder, belonging to the hyperæsthesia and anæsthesia so common in hysterical persons. The symptoms certainly occur, especially in neurotic, hysterical women, and often develop and disappear with a suddenness so characteristic of hysterical accidents. The writer once had an opportunity to watch a case of so-called spinal irritation of the most severe type. The hyperæsthesia was so excessive that the mere touch of a camel's-hair brush upon the back would cause the patient to fall, and he has frequently seen the unfortunate woman lie in an almost syncopal condition for days as the result of some one having brushed against her in passing; and yet this same case, after being fifteen or twenty years confined to the room, recovered in a few days under the influence of the so-called faith-cure. The well-known views in regard to the pathology of the disorder, viz., that it is the anæmia of the posterior columns of the spinal cord, are reiterated in this little book, and supported with all the ingenuity that the author is capable of. The frame of mind in which he approaches the subject is well set forth in the following sentence, which we take from page 53: "It is better to do this, even if the view we enunciate is not absolutely sufficient to account for all the observed phenomena, than to shut up our opinions in our own minds, or, worse still, form none whatever." It is exactly this frame of mind which,

to our thinking, is one of the great drawbacks to modern medicine. When there are no sufficient grounds for forming a theory, it is much better for the mind to rest, and to acknowledge the truth of the facts of the case, and its inability to account for them, rather than to commit itself to some baseless and implausible theory. Careful consideration of the reasons assigned by Dr. Hammond for his belief that this spinal irritation is due to spinal anæmia does not bring to our mind any conviction whatever of the truth of the theory. Most of these reasons are exceedingly trivial. Some of them, indeed, tell very strongly against his belief. He states very decisively that a large blister applied over the tender part of the spine affords prompt and complete relief. Whatever knowledge we have of the action in blisters, all tends to show they are useful, not in increasing the flow of blood in the distant affected organ, but in withdrawing the excess of blood. The treatment of spinal irritation, as given by Dr. Hammond, is exactly that, of a hysterical state, excepting in regards to counter-irritation, and in the great majority of cases such severe measures seem unnecessary and barbarous. The effect of what we may call the credulous mental condition of physicians is nicely illustrated by a statement made by Dr. Hammond that an application of water as hot as can be borne, as a general thing, increases the flow of blood to the spinal vessels. This bold, absolute assertion rests really upon not a single grain of evidence. Hot applications bring relief in some cases of spinal irritation, spinal irritation being due to anæmia. Therefore hot applications increase the flow of blood in the spinal vessels, therefore spinal irritation is due to anæmia. This reasoning in a circle is an epitome of the whole of the book.

MESSAGE AS A MODE OF TREATMENT. By William Murrell, M.D., F.R.C.P.

Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1887.

This is a well-written plea for massage as a means of treating various diseases. We fear that its influence for good will be marred by the tendency that is shown to overstate the value of the method of treatment. There can be no doubt that massage is a most important remedy in the hands of one who knows how to use it; but, after considerable experience, we are convinced that it will not do all that is claimed for it by Dr. Murrell. Speaking of poliomyelitis he says, "By systematic massage

an improvement is speedily effected," and he continues in such a strain as would lead the unwary reader to the conclusion that almost all cases of poliomyelitis are curable by this means. Assuredly this is not correct. All that massage can do in such cases is to maintain the integrity of the muscles, as far as may be, and, if the cells in the spinal cord have a tendency to recuperate themselves, aid in the final return to health. There is no reason to believe that the massage has any direct influence upon the diseased spinal cells, and in the vast majority of cases its most persistent use must end in failure. Then, again, we are told not only that massage is useful in Landys (*sic*) paralysis, but such language is employed as to lead to the direct inference that if massage be employed recovery will take place; for it is said the paralysis in *untreated* cases usually progresses upwards until it involves the medulla oblongata, and death ensues. In true Landry's paralysis massage is probably about as powerless as are other remedies. Then, again, massage is recommended in acute chloral poisoning by Dr. Murrell as a means of maintaining the temperature of the body; for such purposes, in comparison with the hot baths, the method is absurdly feeble. We would recommend, if the experience of our author is to be confirmed, middle-aged ladies to the use of massage. In fact, we may expect the rooms of the *masseuse* to be crowded with middle-aged spinsters hopeful of marriage. Great must have been the glee of Dr. Murrell when he reduced the waist of a lady whose age was reputed to be thirty-five "from twenty-five to twenty inches," and made for her an excellent marriage.

A serious error into which Dr. Murrell has fallen is a misunderstanding of what he terms the Weir Mitchell treatment of neurasthenia, —*i.e.*, the so-called rest-cure. He affirms that in it the massage employed is no massage but simply rubbing. There is no truth in this. The rest-cure, as practised in Philadelphia, dates back to the times of Professor Jackson. The immense improvements introduced into the method by Dr. S. Weir Mitchell consist largely in the use of massage, and the massage as practised upon his patient is a true massage, conforming in all respects with the rules which Dr. Murrell first derived from the older German and French writers. We must also disagree with Dr. Murrell in regard to anointing the skin before the use of massage. The reasons he assigns for performing dry rubbing are as follows: 1. You get

better contraction of the muscles, and consequently a greater flow of lymph; 2. Electrical currents are more readily developed in the tissues; 3. There is a greater elevation of temperature in the part; 4. You do not make your patient in a mess. In answer to this—we rarely, if ever, see distinct contractions of the muscles produced by massage; there is no proof of the assertion that electrical currents are more readily developed in the tissues, or that there is greater elevation of temperature in the part, if the tissues and part are understood to represent those which lie beneath the skin; and, if the anointing be properly done, the patient is not left in a mess. The objection to dry massage is that the massage is apt to become a rubbing, and irritation of the skin to be produced rather than an effect upon the deeper-seated tissues. A little sweet cocoanut oil or vaseline placed upon the skin before rubbing is very often of advantage, especially when there is a tendency to irritability of the skin. In conclusion, we may say that the forms of massage as described by Dr. Murrell are those which are employed by all well-trained operators and recommended in the standard works on the subject.

Correspondence.

LONDON.

(From our Special Correspondent.)

We are now in the depths of the dull season here. Everybody is out of town, excepting your faithful correspondent. No hospitals, no societies. Physicians, surgeons, professors, have silently disappeared to the coast, to the mountain, to the continent, some of them to the Congress. If you ask me how can they be spared, these guardians of the public health, I must tell you that their clients have disappeared too. Everybody that can afford a change takes it at this season, and many who can't pay for a change have it provided for them. The annual holiday appears to be a necessity in these days of restlessness and haste; whether a necessity or no, it is a settled institution. It is not pleasantly received by some of our seniors in medicine, who remain true to the traditions of their youth, and rail at the idleness, as they call it, of these degenerate days. These ancient philosophers class the annual holiday with the penny post and the daily paper among the curses of

modern civilization, and we are as likely to give up the one as the others.

But, as you know, some of us combine work with pleasure, and spend part of our precious change at the great scientific gatherings of the year. This time twelve months ago I gave you an account of the meeting of the British Medical Association at Brighton. I have now to chronicle some events and to discuss a few questions in connection with this year's meeting in Dublin, which are of prime interest to us as therapists.

The president of the Section of Pharmacology and Therapeutics on the present occasion was Dr. Whitla, of Belfast. Dr. Whitla is one of the most advanced and generally distinguished pharmacologists in Ireland. He is a man of learning and enthusiasm, and possesses especially the precious gift of indomitable energy. He is just the man who might be expected to attack and to solve the practical problem of purifying and popularizing his special subject with the profession. Others might lament the lack of fervor in treatment with us, as I have myself done more than once in these pages. Dr. Whitla is not content with wringing his hands: he raises his voice, and gives forth words of encouragement and counsel. He proposes a remedy for the backwardness of therapeutics. He formulates a definite plan for at once extending a proper interest in the action and uses of drugs, and increasing steadily and rapidly, as he hopes, our knowledge of these. The amount of opportunity and experience wasted now in this direction is deplorable; as Dr. Whitla says, "The indication at present is not for more new remedies, but for a better and more precise knowledge of those already placed in our hands. It seems as if one of our very greatest barriers to progress is to be found in the ever-increasing number of new drugs, which pour in upon us at a rate which prevents that thorough testing of their qualities and actions so necessary before the range of the new weapons can be accurately determined. A vast field of almost virgin soil lies at our feet: pathology, chemistry, physiology, pharmacology, and pharmacy have brought in their discoveries and enriched the domain of therapeutics, and if we are to reap the benefits we must be up and doing." All this is very true, and it is well put. About the need for reform, about the crude material from which the perfect instrument of cure is to be produced, about the direction whence good must be looked for, if it come at all, there can be little doubt or division of opinion.

But when we proceed to the *method* of reform we are in difficulty. Here a conflict of opinion will begin. In discussing the cure of modern therapeutics, we find that the better treatment of treatment is as obscure and difficult as the better treatment of disease! Dr. Whitla would have the British Medical Association come to the rescue of therapeutics in this country. He reminds us, most fittingly, that we have in this great society a powerful machine, ready to be set in motion. He would have the Association take up two great pieces of work,—first, “the encouragement of a better method of stimulating therapeutic research” among its members; and, second, the making its voice heard in improving and perfecting our national pharmacopœia. These ends and aims are obviously so desirable, and apply so unquestionably to your country as well as ours, that you will be interested to learn the details of Dr. Whitla’s scheme.

First, then, for “the stimulation of therapeutic research” with us. He would have “a portion of the space of the *British Medical Journal* wholly set apart and dedicated to the ventilation of questions relating to the treatment of disease by members of the Association. A small committee, with a good secretary, would be an essential part of the scheme;” for “to permit the remedies or methods of treatment to be selected by the contributors at random would be to remain precisely where we are. The committee would select one or more remedies whose actions in disease are but imperfectly known, and would invite a full and free discussion and investigation of their virtues through the *Journal* upon certain definite lines previously laid down. In a short time from numbers of workers an amount of valuable experience would be readily obtained which otherwise could not be procured during many years of patient individual toil. Thus there would be yielded an abundant harvest of carefully observed and recorded facts, clearing up many doubtful or exposing many unsuspected actions of certain selected drugs in certain selected diseases. These results, with proper sifting and supervision, might soon become the most valuable additions made to the science of medicine in our time. Many men would probably be induced to devote themselves to the close observation of a limited number of remedies when these would be selected for them, and many other men would be induced to give to the world results already obtained during years of practice, which otherwise they never would have thought of publishing.”

Now this proposal of our president sounded all very well at the first hearing, but it bristles with practical difficulties when regarded dispassionately. To my mind the chief obstacle to its successful accomplishment is that it will meet with something more than indifference from all but the few of us who are specially interested in drug treatment and have a voice in the councils of the Association. If medicinal treatment is to be favored with a special portion of the space of the *Journal*, wholly set apart to it, what about surgical treatment? And what about gynecology, that grossly prolific section of medical literature? Have not these departments as good a claim as therapeutics to a column in the *Journal*, with their special committees, each of them, and their secretary, and their selected subjects calling for ventilation? And if treatment be thus favored, why not pathology and public health? It is desirable to sift and to test not only treatment of every kind, but all portions of the science and art of medicine. The editorial in the *Journal* on Dr. Whitla’s address gave but a half-hearted reception to his proposal, and no wonder. His proposal practically amounts to the disintegration of the management of the *Journal*, and the distribution of the fragments under the supervision of a number of co-editor specialists. If this practical difficulty arise (and I confess I cannot see a way out of it), Dr. Whitla’s scheme will be crushed in its inception. I believe we have yet to persuade many of our men of greatest influence in the profession of the paramount importance of medicinal therapeutics. Until this desirable end has been attained, I fear it is idle to look for special favor for our subject in the columns of the medical press. But there is no reason why something like the first portion of Dr. Whitla’s proposal should not be carried out. We might have an organizing and marshalling of our therapeutical forces, and go forth on a kind of system to attack the opposing host of ignorance, indifference, despair, and superstition with respect to the value of drugs. This might or might not be done by or through the British Medical Association; but the promoters of the movement had better work quietly, and not claim a weekly presentment of their position and results in the columns of a journal.

If I have ventured to criticise the first of Dr. Whitla’s proposals somewhat freely, I fear I must be even less tender towards his second,—that the British Medical Association should busy itself with improving and perfecting our

national pharmacopœia. Dr. Whittle would have us arrange a *plebiscite* of the medical profession on the subject of the common drugs of the British Pharmacopœia in daily use; and he would further appoint another "small committee, with a good energetic secretary, to select new drugs (not in the British Pharmacopœia) likely to have claims to official recognition, and then to invite, aid, and encourage investigation, and report on their actions and values." . . . "No drug would ever be allowed to find its way into the official list until after the most rigorous and exacting scrutiny of its properties by a large number of independent observers."

The first thought that occurred to one on hearing this suggestion was, Why so much fuss and anxiety about a national pharmacopœia? What is a national pharmacopœia to us, or to the science of therapeutics, that we should trouble ourselves about it? How many of us, having found a valuable drug, care, or even ask ourselves, whether it is "official" or not? Is *isthophanthus* "official"? If cocaine had happened to be introduced to the profession a few months after the publication of the new British Pharmacopœia, instead of (as it happened) a few months before its publication, would it be less valuable, less extensively used at this moment? Of course not. We do not question the many advantages, the necessity, of an official guide; but the advantages do not lie in the direction of perpetually "sifting" our remedies into "official" and "non-official." A good drug establishes itself without the help of a pharmacopœia; a useless drug is dropped and forgotten, even though it be bolstered up by official sanction. The London Pharmacopœia deliberately dropped out bromide of potassium in the 1851 edition as being a useless drug; but I am not aware that this bit of sifting interfered with the rapid adoption of the bromides when their influence in epilepsy had been determined. As for a *plebiscite* on the purgation of the Pharmacopœia, surely nothing could be more useless or more likely to end in general discord and discontent. After all, an intelligent pharmaceutical chemist could tell us more in a few minutes as to the value of any given drug in the eyes of the profession than the most elaborate *plebiscite*. He would be able to say what is "asked for" and what lies as wasteful stock on his hands. Useless drugs, like useless men and useless things in general, die a natural death, and may be safely left to their fate.

The matter is perfectly different as regards

the pharmaceutical part of the Pharmacopœia. A pharmacopœia is a pharmacopœia, which, being interpreted, means a treatise on *how to make* medicines. I have already told you in my letter for April, 1887, that the Pharmacopœia Committee of the General Medical Council have a permanent adviser and reporter at work for them, in the person of Professor Atfield, one of the most distinguished and active pharmacological chemists of the day. It is absolutely essential that there should be such an office, filled by such a man, to follow the rapid advance of this department of science, to scrutinize with the greatest closeness, and to put to practical test the many improvements that are published in pharmaceutical methods. Professor Atfield is perfectly able, as I have already suggested, to ascertain the opinion of the medical profession on the therapeutic value of drugs, old and new, and to recommend to the committee for their consideration and decision which substances might be added to the Pharmacopœia and which removed from it. Nothing could be more sensible, and nothing more in touch with the minds of thoughtful men at this moment, than the remarks on a closely allied subject of Professor Leech, of the Victoria University, at the annual meeting of the British Pharmaceutical Congress in Manchester last week. Professor Leech urged his pharmacist audience to keep science ever before their eyes. The prosperity, the evidence, of their profession would depend on their appreciation of the value of scientific methods. We have entered on a new era in the preparation of medicines, and this advance originates essentially in a more correct knowledge of the composition of drugs and the properties of their active principles. To these wise remarks of Professor Leech I would like to add, let us give our counsel a practical shape. If therapeutics, pure and simple, owes a large part of its recent advance to pharmacological research and pharmaceutical improvement, why drift back from the position we have gained by appealing to a *plebiscite* of general practitioners on the value of drugs founded on an experience of old and worthless preparations,—worthless, I mean, from a strictly scientific point of view? Rather let the pharmacologists and pharmacists know that their work is being faithfully and generously followed by one of their own acknowledged heads, in the interest of the medical profession, and we shall stimulate them to still better and greater results; and, what is more, we shall then hear less of the heart-burnings that pos-

sessed the pharmaceutical chemists in 1885 when denied what they considered their legitimate share in the production of our national Pharmacopœia.

PARIS.

(From our Special Correspondent.)

The dulness of summer has been enlivened by an extraordinary communication read before the Academy of Medicine by Dr. Luys, one of its members for the Section of Anatomy and Physiology. The learned academician appears to have gone very far into the *mysteries of hypnotism*, so far, indeed, as to have nearly lost his way. Having repeated Drs. Bureau and Bourn's experiments, and given them more precision by means of photography, Dr. Luys has come to the conclusion that an hypnotized subject can be influenced by medicinal substances held in stoppered bottles, and simply placed in contact with the back of his head. Morphine, for instance, when applied to the left side of the occiput, will cause intense terror and irritation; but, on shifting the vial to the right side, the sedative and pleasurable effects of the drug will readily be observed. Instantaneous photographs of the subjects while under such influences strikingly illustrate the feelings experienced in the case of morphine, as well as the other drugs experimented with. The photos were circulated among the listening academicians. To proceed with the list,—Dr. Luys spoke of eighty-five drugs,—strychnine on the left side will occasion contractions, convulsive starts, etc.; on the right, exhilaration and great enjoyment. With stimulants, such as cognac, rum, champagne, etc., the subject will become stimulated at first, then very gay, and finally so tipsy as to be hardly able to stand, and all that with half an ounce or so of cognac in a vial only touching the head. Dr. Luys forgot to tell his hearers what difference it would make whether the liquor is placed on the right or on the left side. Valerian, haschisch, and other drugs had effects equally characteristic. But in all cases the subject stopped in the midst of the performance, in *statu quo*, when the inciting tube was removed. The most wonderful, however, is still to come. If, said Dr. Luys, in substance, by means of certain drugs, acting purely physically, hypnotized persons can be made to experience such deep perturbations, have their respiration suspended, their nervous centres congested, their cardiac

action disturbed, the experimenter may possibly run the risk of causing death through some imprudence. And should such experiments be conducted by guilty hands, what series of dark crimes may not be committed with impunity, no material proof of the act remaining to bring home a conviction? The sensation caused among academicians by so startling a communication may well be imagined. Some felt as if they had been brought centuries back into the dark ages, while others uttered mild protests of incredulity. The academy having, after a while, regained its composure, decided to appoint a committee to investigate and scrutinize the facts thus brought to its knowledge, a procedure unusual with a member of the learned body, but warranted by the nature of the communication.

As was to have been expected, the medical world outside have shared the sensation and discussed the paper. Already a physician, well known for his familiarity with nervous phenomena and hospital subjects, having recognized from the photographs the one he calls Dr. Luys's star performer, has declared he knows the woman well as a very nervous, hysterical patient, of keen intelligence, and very apt to deceive both herself and any one taking her for a subject of experiments. In fact, the difference between the effects produced by the same substance, when applied to the right or to the left side of the head, reminds one very much of the well-known phenomena of *suggestion*. The subject guesses one thing is expected of her when the glass tube is on the right and another thing when it is shifted to the left, and, in perfect good faith, she will act accordingly.

But, to pass from the supernatural to the real concerns of this material world, physicians are still discussing the question whether *animal vaccine* should not altogether supersede the *humanized virus*, so as to avoid syphilitic contamination. The arguments for and against are too well known to be here repeated, but in the course of his recent lectures at the Hôpital St. Louis, Professor Fournier thus illustrated the difficulty of ascertaining the soundness of the subject supplying the humanized virus. Some fifteen days ago, he said, a gentleman from a country town, married, and the father of a family, came to consult him about secondary syphilitic accidents in the mouth, the result of an amorous escapade. Husbands will do it, even in virtuous America. Proper treatment was prescribed, and the sores were cauterized, the

recommendation being added to have the same done again by his family physician. "Impossible," said the patient; "I can neither go to his office nor ask him to call at my house. Still less can I go to the pharmacist's to have your prescription dispensed." "But, why?" "Because, should the physician call, my wife would want to know what for. On the other hand, should I go to his office, the whole town would know of it, and place on the step the worst possible interpretation, unfortunately too true in my case. As to the medicines, it would be more awkward still. Your prescription would be lying loose about the pharmacy, to be looked at by all the country folks who step in on market days.* Moreover, it is the pharmacist's wife who writes up the bills and accounts, and she would be sure to tell the whole town of my scrape within twenty-four hours." Thus, added Professor Fournier, the family physician of such a patient, being carefully kept from knowing the gentleman's condition, may take vaccine from a child of the family, well convinced nothing is amiss, and so run the risk of propagating syphilis right and left. What may really be the percentage of danger is a question for others to determine; but certain it is that many American physicians must have had similar experience to that related by Professor Fournier.

The physiological effects of *Cytisus laburnum* have been investigated by Drs. J. L. Prévost and Paul Bruet, whose memoir, just read before the Academy of Sciences, brings out the following facts: The parts of the plant experimented with were the flowers, then the green pods, and finally the dry seeds. One point of pharmacological interest may be incidentally noticed,—namely, that *the aqueous extract of the seeds is more active than the alcoholic*. The animals practised upon were frogs, cats, dogs, rats, guinea-pigs, rabbits, and pigeons. With frogs the drug paralyzes the motor nerves, precisely like curare. The animal dies of heart-paralysis. The warm-blooded animals that can vomit are more affected than the rodents are, especially the rabbits. The last are remarkably proof against the effects of laburnum, an immunity that will astonish no one on the part of an animal which feeds with impunity on hyoscyamus and belladonna-leaves. With animals that can vomit, the emetic action is produced

with very small doses, 5 centigrammes ($\frac{1}{2}$ of a grain) of the aqueous extract being sufficient for a cat. The effect occurs within fifteen or twenty minutes of the administration through the stomach, and within six minutes when the drug is given hypodermically. The vomitings were accompanied with violent efforts, but no other symptoms were observed, and no intestinal trouble or diarrhoea. With larger doses general weakness and prostration are produced, hitherto attributed to a narcotic action, but thought by Drs. Prévost and Bruet to be due to a general paralysis of the motor nerves, which ends in death by asphyxia, unless artificial respiration be resorted to. The bilious secretion, and the pupil and cornea of the eye, remain unaffected by laburnum; the same is true of the heart in the case of warm-blooded animals. The conclusions of the memoir are that (1) laburnum may be considered a good emetic, acting promptly, especially when administered hypodermically; (2) with large doses the emetic effect is accompanied by a paralysis of the motor nerves similar to the action of curare, if not identical with it.

The *history of the mustard-leaves*, now so frequently employed, offers some interest, because it shows how discoveries are gradually evolved, and how the man who really finds out the cardinal principle of an improvement is not always the one to profit by the invention, while another, only adapting to it some known device which facilitates its application, will often reap the benefits and attach his name to the discovery. M. P. Vigier, an old and experienced Paris pharmacist, has related the inside history of the mustard-leaves aforesaid. It seems it was Hurant who found first that when mustard flour has been freed, by either pressure or solvents, of its fixed oils, it becomes unalterable on keeping, and considerably more active. But this important discovery was not taken advantage of until long after, when Boggio, another Paris pharmacist, determined to spread a thin coating of the "lean" mustard flour over a paper painted with a thick solution of gum arabic, and to cover the whole with thin muslin, to keep the composition in place. The mustard-leaf may be said to have been then complete, if not perfect. It answered the purpose well. Some improvements only were needed, and they would have come in time had Boggio understood the value of advertising, and thus obtained the pecuniary means and incentive to perfect his preparation. As it was, the dry sinapism dragged along a melancholy

* A French physician's prescription is often a voluminous document, containing many details and directions, besides the formula proper, and all in French.

existence, when Rigollot conceived the idea of substituting for the gum arabic a solution of india-rubber, such as had long been known in industry for waterproofing fabrics. The improvement was undoubtedly an important one, but the chief merit of Rigollot is to have understood his period and vigorously advertised his preparation. This short story bears its own moral.

As a correspondence from Paris would hardly be complete without some reference to *phthisis*, a new cure for consumption will end the present communication. The treatment this time consists in *inhalations of hydrofluoric acid*. Dr. Garcin, in a memoir read on September 20 before the Academy of Medicine, said that the physicians of the Baccarat and Saint-Louis plate-glass factories have for some time observed the beneficial effects experienced by phthysical workmen from exposure to the fumes of the acid. Hydrofluoric acid, both liquid and gaseous, is largely used in the factories for plate-glass engraving, and notwithstanding all ventilating precautions, the gas more or less permeates the workshops. The treatment, based upon this observation, consists in placing the patient in a closet of six cubic metres capacity (about two hundred and fifty cubic feet), where he is to remain for an hour every day. The air of the closet is impregnated with acid fumes by pumping into it a known volume of air run through a twenty-five per cent. watery solution of hydrofluoric acid. The dose varies according to the case. Consumptives of the first degree easily stand twenty litres of acidified air to the cubic metre, which corresponds to two per cent. in volume; for the second degree, fifteen litres are enough; and for the third, ten litres only, and even then it is advisable to run the medicated air through a washing-flask containing some six ounces of water, so as to moisten the atmosphere of the closet and moderate the effects of the acid. Dr. Garcin reports a good percentage of cures by his treatment,—some thirty-five per cent., which he attributes to the destruction of the tubercle-bacilli by the direct action of the acid. However this may be, it must be admitted Dr. Garcin's method is in accordance with the modern theories respecting tuberculosis.

One word more. French delegates to the Washington Congress are beginning to come home, well pleased with their experience and the cordial welcome they received in the American capital. Some speak highly of

their reception in Philadelphia and their visit to the Philadelphia Hospital, over which they grow quite enthusiastic.

PARIS, September 28, 1887.

THE DANGERS OF SANTONIN.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN :—From time to time I see in the GAZETTE reports on the action of santonin, which, in connection with my own experience, makes me doubtful of its harmlessness as an anthelmintic.

I have been using it upwards of twenty years; many a time when strong symptoms of worms were present have administered santonin, and the signs of worms disappeared and the child became well, and yet no worm was seen. It is true I have nearly always exhibited the drug with the old almost universal calomel.

I have often met with cases of remittent and intermittent fevers in which the positive evidence of worms was present. In such cases have uniformly opened treatment with calomel and santonin in sugar, followed quickly with castor oil and spirits of turpentine. In such cases as the above I often note a marked disposition to convulsions at once, and at last to gastro-enteric or verminous fever. I have several times seen cases of obstruction of the bowel caused by the winding together of the dying worms caused by the use of santonin, and nervous and spasmodic trouble soon supervened. I have thought that the use of santonin for the riddance of worms was more liable to such misfortune than any other vermifuge that I have used. Before I ever used santonin, and in the employment of other worm-destroyers, I have often found a great variety of nervous symptoms and very threatening indications to arise as soon as the worms were disturbed or destroyed. Have not all practitioners, whether in the use of santonin or some other worm-medicine, encountered some strange departures from the usual course of verminous disease? A malady that can cause night-terrors with all its phantasmagoric visions can also produce blindness, and has done so often when the stomach and brain have been long in morbid reciprocity by the presence of worms in the stomach. We may not be surprised at heart-symptoms resembling the action of a powerful heart-depressant, or any other death-symptom which may have direct relation to the stomach or brain.

My first use of santonin was in my own son, 6 years old. He had night-terrors. I exhausted the catalogue of anthelmintics and tonics, mineral and vegetable. He got no better, but worse, until his frights at the sight of familiar friends at times threatened convulsions, and then temporary blindness was increasing in duration. I gave him santonin, per mouth and per rectum, morning and night, 3 grains each way. No worms appeared, and yet his night-terrors stopped to return no more. A young man, 21 years old, clerk in a drug-store, had night-terrors, and consulted me on the subject. I ordered santonin and calomel each night for two nights. He laughed and said he was not wormy, and for a time refused to take the prescription; but at last he did take it, and his terrors ceased, though no worms appeared.

I have had better success with santonin in the treatment for worms than any other vermifuge that I have used; have had as few strange departures from what is common to verminous diseases under its use as under any other worm-medicine that I have used. I do hope its medicinal properties and therapeutics will soon be settled.

THOS. H. STEWART.

TREATMENT OF EPISTAXIS.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—For the past five or six years I have practised exactly the same treatment in epistaxis as that recommended by Dr. J. Robinson, of Manhattan, Kansas, on page 568 of vol. xi. of the GAZETTE. In every instance the treatment has been entirely successful. I am unable to tell at the present time from what source I received the idea.

Yours truly,

F. W. PUTNAM, M.D.

BINGHAMTON, N. Y.

"THE NEW REMEDY FOR NIGHT-SWEATS."

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—I have just read the article of Dr. Fliesburg in the September number of the THERAPEUTIC GAZETTE. It seems that the doctor is highly incensed that I should have occupied a small space in your journal to call the attention of the profession to a

remedy for night-sweats. He should be glad, however, that I did so, because it has given him the opportunity to abuse me and to air his chemical knowledge. Education and politeness should go hand in hand: the doctor seems to possess the first to an eminent degree, Ph.G., M.D. Now, I did not mean to be personal to the doctor in my article: I did not know that Oscar Alf. Fliesburg, Ph.G., M.D., existed. If, however, he has in the course of his practice used medicines discovered by others, and claimed for himself the honor of discovering them, and therefore feels hurt that I said in my article that this had been done by members of the profession, and I thus hit him unawares, why, I am truly sorry. It seems to me, however, that before criticising me and the remedy I proposed he should have at least given it a trial, and if on doing so it had failed to accomplish the end, then he could have said, "I have tried it and it will not do what Dr. Pope claims for it." I have used the cinquofoil in a case since the publication of my article, and it has again proven successful. The profession I hope will give it a trial notwithstanding Dr. Fliesburg's article, and I hope that the doctor will do the same.

Very respectfully,

SAMPSON POPE, M.D.

NEWBURY, S. C., October 1, 1887.

Notes and Queries.

THE THERAPEUTIC VALUE OF OLEUM HYOSCYAMI AND OF OTHER "OLEA COCTA."

As is well known, the oleum hyoscyami and other "oils" of narcotic herbs are merely olive oil (or some other bland fatty oil) which has been impregnated by heat or other means with whatever constituents were soluble in the oil. Generally more stress has been laid upon the appearance of these preparations than upon their alkaloidal contents, a handsome green color being above all highly prized.

MR. DIETERICH has recently examined some of these products, made by himself with all possible care. Having previously analyzed the extract made from the same hyoscyamus which was utilized in the preparation of the "oleum hyoscyami," and having found this to contain at least 0.75 per cent. of hyoscyamine, he ascertained that a corresponding portion of the oil contained only

about one-fifteenth of this quantity of alkaloid. Before describing his *modus operandi* in the assay of the oil, we will give a brief abstract of his method of assay of extract of hyoscyamus and of other extracts :

Triturate 0.2 gm. of powdered lime, made by ignition from marble, with 3 gm. of water, and mix this well with 2 gm. of the extract to be examined (assuming it to be either belladonna, conium, aconite, or hyoscyamus). When it is dissolved, add 10 gm. more of powdered lime, and rub until a dry powder results. By means of a continuous extraction apparatus extract the mass, packed in a little glass cylinder, with ether. In the case of belladonna, aconite, and hyoscyamus the extraction will be completed in about forty-five minutes. In the case of conium, at least two hours will be required. To make sure, the extraction with ether ought to be repeated. Transfer the ethereal solution to a capsule, rinsing the flask in which it has been contained with ether. Add 1 c.c. of distilled water and evaporate the ether carefully on a water-bath at a temperature not exceeding 30° C. (86° F.), taking care that no vapors of any volatile acid (nitric, hydrochloric, acetic, etc., acid) come in contact with it, to prevent even the slightest trace of the respective alkaloids from being neutralized. Dissolve the final residue in 0.5 gm. of diluted alcohol (sp. gr. 0.892), dilute the solution with 10 c.c. of distilled water, add 1 or 2 drops of rosolic acid solution (1 to 100 alcohol), titrate with $\frac{1}{100}$ normal sulphuric acid,—that is, such as contains 0.049 gm. of H_2SO_4 in 1 litre, or of which 1 c.c. contains 0.00049 gm. of H_2SO_4 .

Each cubic centimetre of this acid neutralizes, respectively, according to the author,—
0.00289 gm. of atropine or hyoscyamine.
0.00523 gm. of aconitine.
0.00127 gm. of coniine.

For extract of belladonna, the author had found the results to vary between 1.142 and 1.184 per cent. in alkaloids.

Extract of aconite, between 1.252 and 1.305.

Extract of conium, 0.589 to 0.622.

Extract of hyoscyamus, 0.551 to 0.780 per cent.

Coming back now to the oleum hyoscyami, we will give the process followed by the author in assaying it.

500 gm. of the oil were shaken with four successive portions of 200 gm. of alcohol mixed with 4 drops of diluted sulphuric acid. The united liquors were filtered and evaporated on a tared capsule at a gentle heat (not ex-

ceeding 60° C. = 140° F.) until the residue amounted to 10 gm. This was mixed with 50 gm. of water in a test-tube, the mixture well shaken, filtered through a wetted filter, and the residue left behind once more treated in the same manner. The united acid filtrates were again evaporated below 60° C., triturated with 2 gm. of powdered lime, afterwards with 10 more gm. of the same, and the mixture extracted with ether precisely as described in the preceding process. The ethereal extract was evaporated to 1.5 gm., mixed with 0.5 gm. of diluted alcohol (0.892), and then with 10 gm. of water. Next, 1 drop of solution of rosolic acid was added, and, lastly, enough of the $\frac{1}{100}$ sulphuric acid, of which 3.5 c.c. were consumed, which correspond to 0.010115 gm. of hyoscyamine in the total 500 gm. of the oil.

Diederich states correctly that the process followed in making these oils from narcotic herbs is faulty in this,—that the alkaloids are not set free from their salts so as to enable them to be dissolved by the oil. He therefore proposes to set the alkaloids free by the use of ammonia, which has the further advantage that it greatly increases the brilliancy of the green chlorophyll color upon which so much weight is laid. He found that this use of ammonia increased the quantity of hyoscyamine contained in the oil to triple the amount present in the ordinary preparation. The process he recommends is as follows :

Mix 20 parts of water of ammonia (sp. gr. 0.960) with 750 parts of alcohol, moisten with it 1000 parts of coarsely-powdered hyoscyamus-leaves, firmly press the damp powder in a porcelain vessel, tie parchment-paper over it, and let it stand twelve hours. Next, transfer it to a large porcelain vessel, pour upon it 5000 parts of olive oil, stir well, and heat it, under occasional stirring, upon a steam bath, at a temperature of 50° to 60° C. (122° to 140° F.). Then express and filter. A higher temperature results in loss of alkaloid.—After *Rundschau* (Prag), No. 17; *American Druggist*, July, 1887.

PAPAYOTIN IN FISSURES OF THE TONGUE.

SCHWIMMER (*Wiener Med. Woch. ; Nouv. Remèdes*) has succeeded in the treatment of fissures of the tongue with papayotin after failure with chromic acid, iodoform, and nitrate of silver. He used a solution of from 1 to 2 parts of papayotin in 10 parts each of

glycerin and distilled water, applied five or six times a day, the fissure being previously well dried. No maceration takes place, but the pain is stopped and the epithelium renewed. The treatment was used in twenty-five cases, all of which were completely cured, except one, which was of a syphilitic nature, and in that case, although antisyphilitic treatment had failed, amelioration followed the use of papayotin.—*New York Med. Journ.*

THE DIGESTION OF CARBOHYDRATES.

The paper of Ellenberger and Hofmeister, recently published in *Biedermann's Centralblatt*, contains a summary of their long-continued researches on this subject. They have experimented upon the horse, and their conclusions are by no means identical with those that have hitherto been received. An abstract, by MR. J. FLETCHER, of this important paper appears in the current number of the journal of the Chemical Society; and it is so lucid and concise that we reproduce it almost *in extenso*.

"The action of saliva in the process of mastication is shown to be more mechanical than chemical. The quantity of saliva used depends on the dryness and roughness of the food rather than its contents in starch; and the authors think that the chemical activity of saliva owes much to spores, which, floating in the atmosphere, mix with the food and assist in the fermentation process. A digestive action of the mixed food takes place in the stomach when the acidity due to hydrochloric or lactic acid does not exceed 0.03 to 0.04 per cent. The left section of the stomach of the horse does not secrete a gastric juice; this is the function of the right portion. The pure gastric juice of the horse contains lactic, fatty, and amylaceous ferments,—the latter in small quantities. Cellulose is not digested in the stomach of the horse, but muscle, fat, gelatin, and flesh generally are easily digested, bone and elastic tissues more slowly. Pepsin operates actively only when acids are present, about two per cent. of lactic acid or 0.2 per cent. of hydrochloric acid being necessary. The activity of pepsin does not increase in proportion to its quantity after reaching a certain point, but it rather becomes injurious. The acid which appears first in the digestive process is lactic acid, and later hydrochloric; at the time of greatest activity lactic acid is present in the upper and

lower extremities of the digestive tract, hydrochloric acid being found in the intervening part. The digestion of starch in the stomach of the horse lasts for about two hours; that of albuminous matter takes place later, and occupies three or four hours after the eating of the food. The drinking of water immediately after food does not appear to hinder digestion. The secretions of the intestinal canal unite in themselves all the properties of the gastric juice, and can act as a substitute for it, and are particularly energetic in the decomposition of fats. The duration of the digestive process in the horse is long, lasting almost three days. A very active lactic fermentation of sugar takes place in the stomach and intestines, but the authors do not say that all the sugar which is lost in the course of passage is lost in that way; it is more probably reabsorbed."—*Lancet*, August 27, 1887.

CHANGES IN MILK PRODUCED BY FREEZING.

KAISER and SCHMIEDER experimented with two samples of milk, freezing one slowly, the other quickly, and afterwards partially thawing them. In the former case the ice contained the greater part of the fat, and the fluid portion most of the casein, milk-sugar, and salts. In the quickly-frozen and partially-thawed sample the fat was equally distributed between the solid and fluid portions; the author explains this by the fat-globules rising to the top when the process of freezing is gradual; they thus become embedded in the flakes of ice, whilst in quickly-frozen samples this cannot take place, and the fat is more evenly distributed. If a dealer whose milk has been frozen pours off the clear fluid which underlies the ice, he is liable to the suspicion of adulteration on the one hand, or will deliver milk above the standard on the other. Milk which has been frozen should be well thawed and shaken up, and not sold whilst any ice is visible.—*The Pharmaceutical Journal and Transactions*, September 10, 1887.

ACETANILIDE.

In an interesting article in the *Centralblatt für Gesamte Therapie*, by DR. GABRIEL PAVAI-VAJNA, concerning the use of acetanilide, or antifebrin, the author asserts the superiority of antipyrin over antifebrin, and also speaks of the importance of giving the

drug in small doses. He sums up his experiences with antifebrin as follows :

1. Antifebrin in small doses will be found to actively reduce the temperature. A dose of 0.25 to 0.50 centigramme ($3\frac{3}{4}$ or $7\frac{1}{2}$ grains) will reduce a high temperature from 1° to 4° C. Care, however, should be exercised, as in some weak patients 0.25 centigramme has been known to cause collapse, and, again, in other cases, 1 gramme has had no effect.

2. The fall of temperature will begin in one to three hours after taking the drug, and will remain down for two to four hours, and in most consumptives from eight to ten hours. The temperature will then rise quickly, without, however, any accompanying chills.

3. In nearly all cases slight perspiration occurs, rarely collapse or cyanosis.

4. Antifebrin has no effect on the respiration. The pulse usually decreases with the temperature, although not always proportionately.

As antifebrin, even when given in large doses, has no effect on the heart's action, it can, therefore, be given to those fever cases who have heart-failure or the like, when antipyrin or salicylic acid would be dangerous.

5. Antifebrin seemingly affects but slightly the digestive organs. Even when thirty to forty doses were given daily no nausea, vomiting, pain, purging, or dizziness was experienced.

6. Antifebrin is given with the greatest certainty and best results in articular rheumatism and phthisis pulmonaris. In rheumatism it is of equal value with salicylic acid, and in phthisis it is superior to quinine, and in some cases superior to antipyrin.

CARBOLIC ACID AS A SAFEGUARD AGAINST INSECTS.

Many people do not know how easily they can protect themselves and their children against the bites of gnats and other insects. Weak carbolic acid sponged on the skin and hair, and in some cases the clothing, will drive away the whole tribe. A great many children and not a few adults are tormented throughout the whole summer by minute enemies. We know persons who are afraid of picnics, and even of their own gardens, on this account. Clothing is an imperfect protection, for we have seen a child whose foot and ankle had been stung through the stocking so seriously that for days she could not wear a leather shoe. All this can be averted accord-

ing to our experience, and that we believe of many others, by carbolic acid judiciously used. The safest plan is to keep a saturated solution of the acid. The solution cannot contain more than six or seven per cent., and it may be added to water until the latter smells strongly. This may readily, and with perfect safety, be applied with a sponge. We have no doubt that horses and cattle could be protected in the same way from the flies, which sometimes nearly madden them, and it even seems possible that that terrible scourge, the African Tsetse fly, might be kept off in the same manner.—*The Lancet*, June 25, 1887.

TWO NEW ALKALOIDS OBTAINED FROM THE BARK OF THE ARTAR-ROOT.

GIACOSA and MONARI, who have examined the bark of this plant, which inhabits the eastern coast of Africa, gave the following as the result of the examination: If a small piece of the bark is retained in the mouth it produces a sensation similar to that occasioned by the application of the poles of a constant current. By extracting with petroleum ether they separated a heavy, fatty oil, not crystallizable, with the taste above described, and a cholesterin which melts at 120° to 130° . By suitable treatment of the alcoholic and ethereal extract they obtained two entirely different alkaloids. One occurs in greater quantity, soluble in ether, insoluble in water, non-crystallizable, forming yellow salts with sulphuric, nitric, and hydrochloric acids, and does not show the reactions of berberine. It was critically examined in some of its combinations, and isolated, but its formula has not yet been determined. The second alkaloid exists in small quantity, crystallizes in beautiful red tablets, is soluble in water, and also yields yellow salts with acids. It was not subjected to further analysis. The physiological effect of the first alkaloid is not unlike that of veratrine. Its action upon the heart manifests itself in reducing the rapidity of the contractions with apparent increase of the force. The heart resists the action of this alkaloid for some time. Nothing is said of the action of the second alkaloid.—*Intern. Klin. Rundsh.*, 1887, 27; *Pharm. Record*, August, 1887.

THE DANGERS OF ANTIPYRIN.

Our remarks in the preceding number of the GAZETTE as to the dangers of antipyrin have received confirmation in a note published by the Paris correspondent of the *British Medi-*

cal Journal (August 20, 1887). The instance he refers to occurred in the practice of Dr. BERNOUILLE, of Basle. The patient was a strong, well-nourished woman, aged 52, suffering from chronic rheumatic arthritis of about three months' standing. During the first week of the antipyrin treatment she took 15 grammes, the daily dose varying from 2.5 to 4.0 grammes ($37\frac{1}{2}$ to 60 grs.). This was well borne. Subsequently, however, on three different occasions, the administration of a 1-gramme dose of antipyrin was followed in three or four minutes by severe pain in the chest and abdomen, mental anxiety, cold perspiration, followed by rapid rise of temperature, reaching to 39.2° and 40.2° C. The pulse was 120 and full; there was vomiting, with swelling and redness of the face, and an erythematous rash all over the body. These symptoms gradually disappeared a few days after discontinuing the remedy. Similar cases have been reported by Drs. S. Laache in the *Centralbl. f. Klin. Med.*, vol. vii., 1886, p. 32, and A. Fraenkel in the *Deutsche Med. Wochenschr.*, No. 49, 1886.

ALKALINE MERCURIAL SOAP AS AN ABSORBENT.

DR. SVETUKHIN, chief of Professor Lashkevich's clinic in St. Petersburg, in some therapeutic notes contributed to the *Russkaya Meditsina*, mentions that various preparations have been recently employed in the wards for the purpose of promoting absorption of pleuritic effusion. Iodine ointment is too mild and too slow in its action to answer the purpose, and the odor of iodoform ointment is so strong that it interferes too much with the comfort of the other patients, and so is found to be unsuitable for hospital practice. It was found that iodine ointment could be advantageously supplemented by soft soap (*sapo kalinus viridis*) inunctions, or by rubbing in unguentum hydrargyri. The most valuable of all applications for this purpose was, however, found to be a preparation called *sapo kalinus hydrargyrosus*, which is made by mixing in certain proportions metallic mercury, unguentum hydrargyri, caustic potash, and olive oil, so that the resulting soap contains a third of its weight of mercury, the unguentum hydrargyri of the Russian Pharmacopœia containing half its weight of mercury. This is agitated with hot water so as to form a good froth and lightly rubbed into the skin. It has the advantage over unguentum hydrargyri in being much more easily rubbed in, in not ir-

ritating the skin, and thus causing eruptions, and, lastly, in not so rapidly setting up stomatitis or salivation. From half a drachm to a drachm of this mercurial soap is used for each inunction. After from six to ten applications some diminution may be detected in the effusion, and after twenty inunctions the whole is usually found to have disappeared. Of course, favorable results can only be looked for in cases of simple effusion; they cannot be obtained in empyema.—*Lancet*, August 6, 1887.

CYANIDE OF ZINC IN CARDIAC AFFECTIONS.

Cyanide of zinc exerts, according to PROFESSOR LASHKEVICH, a beneficial effect on some cardiac cases which cannot be obtained by other means. In cardiac neuroses it acts quickly and certainly. Palpitation, want of rhythm, and pain in the region of the heart are quickly affected, sometimes indeed cured, by this drug. The dose is from $\frac{1}{16}$ to $\frac{1}{4}$ of a grain three times a day. Similar beneficial effects are produced when there is organic cardiac disease. The regulating action of cyanide of zinc in valvular insufficiency is less marked than its effect on cardiac neurosis; nevertheless, there were cases in the wards where it acted better than other cardiac remedies, as digitalis, convallaria majalis, adonis vernalis, etc. In this respect it acted particularly satisfactorily in cases where other remedies could not be given without producing derangement of the gastro-intestinal system. Here it improved the action of the heart, thus increasing the secretion of urine, moderating the pulse, and diminishing the dropsy due to irritation of the gastro-intestinal canal. In a case of nervous palpitation with hysterical anuria, cyanide of zinc diminished the palpitation, and at the same time caused the secretion of urine to recommence.—*Lancet*, August 6, 1887.

A CONVENIENT PRESCRIPTION FOR THE ADMINISTRATION OF PHOSPHORUS.

SALTMANN has found oil of almonds an especially good medium for the use of phosphorus, and prescribes as follows:

R Phosphori, gr. $\frac{1}{4}$;
Ol. amygdalar., \mathfrak{z} iiss;
Aque dest., \mathfrak{z} iiss;
Gummi arab., \mathfrak{z} iiss. M.
Ft. emul.
Sig.—Dose, 1 teaspoonful.

NEW ANTISEPTIC METHODS OF TREATING PULMONARY DISEASES.*

BY PROFESSOR DUJARDIN-BEAUMETZ, Paris, France.

GENTLEMEN:—In a series of lectures on "New Medications," which I had the honor to deliver before you a couple of years ago, I endeavored to show you that although the method of antiseptics, in its application to pulmonary diseases, was still in its infancy, yet there was every reason to expect from such antiseptic medication, when

founded on the rational observation of the causes of diseases, brilliant results in the future. It must, indeed, be confessed that we have not made as rapid progress in this direction as we could have wished; but this is not at all surprising, considering the difficulties which we have at every step to encounter in adapting the principles of antiseptics to the treatment of pulmonary affections.

In fact, to state the matter plainly, the rational application of antiseptic methods implies several conditions: first, the perfect knowledge of the microbe itself, and the conditions in which it develops, reproduces itself, and dies. We must know, too, its degree of resistance, and especially its degree of vitality,

* A lecture delivered in Cochin Hospital.

as contrasted with that of the organ where it vegetates; and this last condition is practically the most important of all. In fact, the lung is an organ pre-eminently essential to life; and if, in attempting to effect destruction of the germ of the disease you injure the organ which is its habitat, you will have left the subject in a worse state than before.

Antiseptic inhalations—a subject to which we shall shortly return—have not given all the results that they promised. For this there are several reasons,—first, a number of these antiseptics are irritant substances, whose use cannot be prolonged with impunity, and which soon determine in the larynx, trachea, bronchi, and even in the lungs, symptoms of irritation and inflammation which cannot but be prejudicial to the patient. Moreover, the lungs are an effective channel for absorption into the blood, and, as many of the best antiseptics are toxic, and the patient in carrying out the treatment would necessarily inhale considerable quantities, there would be more or less danger of systemic poisoning. Lastly, there is another difficulty in the way, owing to the fact that recent experiments have proved that in inhalation atomized saline or other substances penetrate with difficulty to the last bronchial ramifications, and that the greater part of these sprays are retained in the upper air-passages. The physiological experiments on animals undertaken by Professor Jacobelli, of Naples, with his ingenious atmimeter, before the Commission appointed by the Academy, have shown us how questionable a matter is this penetration of vaporized solutions to the ultimate bronchi; and my colleagues of this Commission—Marey and Brouardel—have shared my doubts on the subject.*

You are well aware, gentlemen, that the pulmonary diseases of microbic origin are not numerous, and that it is to the treatment of tuberculosis especially that clinical investigators are now directing their energies. The discovery of the bacillus tuberculosis has opened up a new line of experimentation, and, I may add, a rational and scientific one, for those who are seeking for more radical therapeutic methods in this formidable disease, which makes such ravages among our civic populations, and especially among the poorer

classes, who, by reason of want of hygiene, bad alimentation, alcoholic excesses, offer an excellent culture-field to the parasite.

Unfortunately, the tubercle-bacillus is a micro-organism characterized by great resistance and difficult to overcome, considering its vitality and its ability to tolerate very energetic treatment. For this reason, and for those which I have just mentioned, it has been thought prudent to cease attacking it from the front, and to seek other and safer methods of getting at the enemy. It is these new methods which I am going to make the subject of my present lecture,—methods which, I believe, indicate a real advance in the antiseptic treatment of pulmonary diseases.

All these antiseptic measures, without exception, attempt to realize this fundamental intent: to bring in immediate contact with the pulmonary mucosa and the air-cells the antiseptic substances. Of the three procedures which have been proposed to attain this end, the first is that of parenchymatous injections made directly into the pulmonary tissue. This method, advocated by Lépine, Truc, and Gouguenheim, has been abandoned for reasons which I have before given you. By another process, we seek to avail ourselves of a property possessed by the pulmonary textures, of elimination by exhalation through the air-cells of substances introduced into the blood. The third method is, in principle, the older one, of direct inhalation by the buccal passage of antiseptic medicines. It remains for me to speak of these two procedures, that of exhalation and that of inhalation. I will begin with the former.

Instead of directly introducing the medicinal substance into the lungs by the air of respiration, we first cause it to enter the circulation by some process; then, in being eliminated at the surface of the lungs, it comes in contact with the diseased parts, and thus enters into conflict with the morbid germ. As absorption by the lungs is left out of the case, there remains only absorption by the subcutaneous tissues, or by the digestive tube; in other words, the medicament must be introduced hypodermically, or by the stomach or rectum. In phthisical patients the stomach is often not in a good condition for the reception and absorption of medicaments; and by reason of the facility with which vomiting may be induced, or the stomach otherwise irritated, and of the necessity of keeping this organ in a sound con-

* "On the Atmimeter of Professor Jacobelli." Report presented in the name of a Commission composed of MM. Brouardel, Marey, and Dujardin-Beaumetz. (Academy of Medicine, session of August 2, 1887.)

dition in order to nourish the patient, we are obliged to choose the hypodermic method, or avail ourselves of the property of absorption possessed by the rectum, in order to carry out our intent.

You know the inestimable service rendered by phenic acid to surgical antiseptics. It is not surprising, therefore, that, considering the volatility of phenic acid, and its elimination by the pulmonary passages, it should have occurred to clinicians to utilize this agent in the treatment of pulmonary tuberculosis. A number of experimenters, among whom should be mentioned Dr. Filleau and my former pupil, Dr. Leon Petit, have attempted to practise subcutaneous injections of phenic acid in phthisis. I have myself made trials of this method in my hospital service, and my interne, Sapelier, has put on record a series of interesting observations pertaining to this subject.

The phenic acid injections may be made directly under the skin, or the needle may be plunged deeply into the soft parts, and even to the seat of the lesion when the injection is made in the region of the thorax.

Professor Lépine and his pupil Truc were among the first to venture intra-pulmonary injections in tuberculous patients. They made use of creasote, a two per cent. solution in alcohol, preceding this injection by one of morphine to prevent pain. They also advised iodoform injections in tuberculous cavities, as these injections had given brilliant results in abscesses of a tuberculous nature.

An ordinary hypodermic syringe is inadequate for these deep injections of phenic acid, and it would be necessary for you to make use of a larger kind, a specimen of which I here show you, and which holds five grammes of liquid. You can employ a two per cent. solution, having care to use only the pure phenic acid, previously dissolved in glycerin, which is less irritant than alcohol.

You will choose as the place for the injection the anterior part of the chest under the clavicle. The punctures should be made more or less often, according to circumstances, and their number should vary, according to the gravity and course of the disease, from two each week to two each day. Under no circumstances should they be too often repeated, for in exceeding a certain dose of the medicament you run the risk of seeing all the symptoms of carbolic-poisoning make their appearance,—coldness, cyanosis, collapsus, vomiting, black coloration of the urine.

Moreover, some persons are particularly intolerant of this medicinal agent, and cannot with safety be subjected to this treatment.

In spite of some disasters, the injections of phenic acid have given quite favorable results in a certain number of cases. Almost always the appetite is improved; patients that previously were bedridden are able to get up and go out and take the air,—a great advantage in consumption, as you know. The cough and expectoration have diminished, and, what is also very gratifying, we have often seen the night-sweats, so painful to poor consumptives, disappear.

At the same time the injections of phenic acid are, as I before intimated, not without danger. Besides the risk of poisoning which you run if you resort to them, they are often irritant, and they have not entered into current practice. They ought, however, to be retained for exceptional cases, where they will afford real relief to patients. I shall return farther on to the subcutaneous method, and you will then see what progress has been accomplished by the discovery of new vehicles capable of rendering perfectly innocuous substances otherwise very irritating.

We come now to the method of gaseous rectal injections, first brought before the profession by Dr. Bergeon, of Lyons, a method founded on the labors of Cornil and Chantemesse, who had shown that among the gases capable of hindering the development of the bacillus tuberculosis the first place should be accorded to sulphide of carbon and sulphide of hydrogen. These gases are both toxic when respired in vapor, therefore it would not do to think of utilizing them by inhalation. Bergeon, inspired by a happy idea, showed how to introduce them into the economy by the rectum, and this is the really new feature of his method.

We knew already from Claude Bernard's remarkable discoveries, that, in order that a toxic substance may produce its characteristic effects, it must enter the arterial system and be thence disseminated through the organism; and, if it can be eliminated before being taken up by the arteries, it fails to produce its noxious results.

Such being the case, the introduction of toxic and antiseptic gases should be made by the intestinal canal, and as we have seen that we must respect the stomach, the rectum is the only available channel. In fact, by using the rectum as a medium of absorption, we can introduce into the economy a great quantity of hydrogen sulphide without causing

toxic symptoms. The gas after being absorbed traverses the portal system, and consequently the liver, the first emunctory for the elimination of poisons; then it reaches the lungs, where the greater part passes through the parenchyma and escapes by exhalation.

The quantity of gas administered (or the dose, if I may so call it) must not be too large, for you would run the risk of an incomplete elimination, and a part, passing into the arterial system, might determine symptoms of poisoning. Moreover, the sulphuretted hydrogen, which is so toxic, cannot be used in a state of purity; it must be diluted with some other gas. Air being too irritating, Bergeon made his choice of carbon dioxide, which is not irritant, is readily eliminated by the respiratory passages, and, besides, possesses anæsthetic properties well known to you.

He thus exhumed from the past, as Maurice Dupont has shown,* a method counselled at the close of the last century by Priestley, who recommended to the physicians of the period to employ *fixed air*—i.e., carbonic acid—in lavement in the treatment of certain diseases.

The method of Bergeon became known by the various communications made by him to the Academy of Sciences and the Academy of Medicine. I immediately made application of it in my hospital service, and one of my pupils, Dr. Lecomte, has analyzed the results obtained, and made this the subject of his inaugural thesis.†

Let us now take a survey of the apparatuses employed for these gaseous rectal injections. The one employed by Bergeon was the invention of Dr. Morel, of Lyons; the one which I have used in my hospital was constructed by Dr. Bardet, chief of my therapeutic laboratory. There is another which I shall describe presently, which was contrived by Dr. Faucher and was presented to the Academy by Professor Cornil. Lastly, Constantin Paul has also devised a gazogenous apparatus, furnished with a manometer, which enables one to measure

the pressure of the carbonic acid which penetrates the rectum.

In the apparatus of Morel, the carbonic acid is generated by pouring sulphuric acid on bicarbonate of sodium in a flask. The complete apparatus consists of a flask in which the carbonic acid is generated, of a rubber bag capable of holding six litres of carbonic acid, of a large, wide-mouthed bottle to contain the medicinal substance, and of a rubber-ball injector, which acts the part of a suction- and force-pump. The rubber bag having been filled with carbon dioxide, is adapted to the bottle, which is itself connected with the injector. It is necessary to take care before introducing the canula into the rectum to get rid of all the air contained in the apparatus by making a few pressures on the rubber ball.

This apparatus presents certain inconveniences: first, the use of sulphuric acid is an objection, for some of it is sure to come over with the carbonic acid during the effervescence and vitiate the result by the irritation which its presence causes. Then again, it is too cumbersome, and is not sufficiently portable, which is a serious inconvenience in private practice; therefore, at my request, Dr. Bardet has constructed another model in which all the parts are brought together in a convenient, portable box, and in which the carbonic acid is produced by the action of tartaric acid on the sodium bicarbonate.

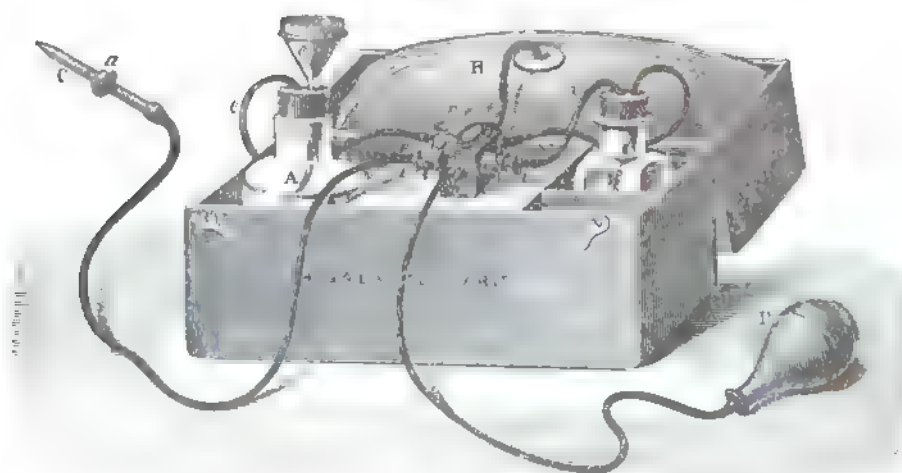

The apparatus (Fig. 1) is composed of a box with compartments occupied by (1) a carbonic acid generator, A; a wide-mouthed bottle resembling a wash-bottle, B (the *barboteur*, or mixing-bottle), and (3) an injector, I, a pear-shaped rubber ball, P, and a canula, C, etc. The canula C, with its tube, are the only parts which are outside of the box during the working of the apparatus. The injector I, whose operation depends on a play of valves, *i* and *i'*, is a solidly-fixed metallic box, connected with all parts of the apparatus by means of tubes, *r*, *r'*, *t*, with their faucets and stop-cocks.

The gas furnished by the generator A escapes by the tube *a*, which is connected by the faucet *r* with the central metallic piece I, whence it issues by the tube *t* to enter the reservoir R. Here it is retained by the resistance of the liquid in the wash-bottle B. When once the bag R is filled, the apparatus is ready to work. The operator squeezes the ball P, forcing out the air which it contains, and which escapes by the valve *i'* and canula. Then the ball expands by its elasticity, exercises its suction-power, and fills

FIG. 1.

itself with gas from the reservoir R. This gas first passes out of the reservoir, and under suction influence enters the receptacle B by the tube *v*, which dips down to the bottom of the vessel, where it becomes charged with medicinal vapors; then it escapes by the exit-pipe *v'* to enter the injector, which it then fills, as well as the rubber ball P; the operator now presses the ball and forces the gas out through the valve *r'* and the canula C, and continues so to do till the rubber bag, which holds just four litres, is emptied, which event makes itself known by the rubber ball remaining collapsed after being squeezed. To prepare the apparatus for use, you proceed in the following way:

1. Pour into the receptacle B enough to fill it half full of the medicinal solution which you propose to use (sulphur waters, carbon bisulphide water, warm water holding in suspension iodoform, terpinol, eucalyptol), then put in the stopper.

2. Place in the generator A the contents of a package consisting of sixteen grammes of tartaric acid with twenty grammes of bicarbonate of sodium,—a quantity necessary to generate four litres of carbon dioxide. Fill the generator half full of water by means of the funnel *c*, and shake the flask.

3. Have care to drive all the air out of the apparatus by four or five squeezes of the rubber ball before introducing the canula.

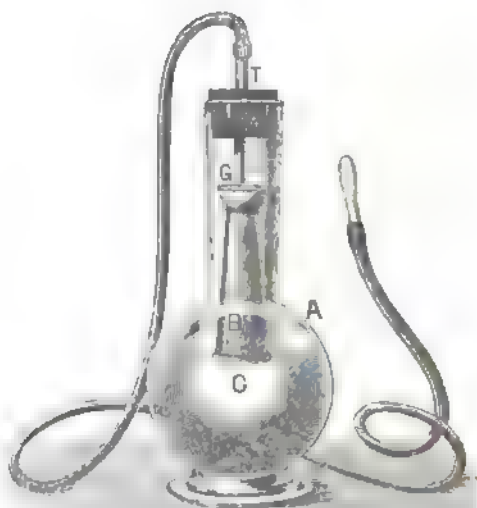

4. The injection should be made slowly and without force; there ought to be an interval of from ten to fifteen seconds between the successive pressures made on the injector, and the entire operation should last from twenty minutes to half an hour.

As for the apparatus of Faucher, it is com-

posed (1) of a flask, A (see Fig. 2), which receives the sulphuretted water and a package of sodium bicarbonate; (2) of a reservoir, B, which is filled with bisulphate of sodium; this reservoir is connected with an escape-pipe, which traverses the rubber cork which closes the flask; (3) of a rubber tube ending in a canula.

To work the apparatus you plunge the lower part of the reservoir B into the alkaline water by pressing on the, pipe T. The

FIG. 2.

gas escapes slowly and penetrates the intestine when the pressure is sufficient. If you wish to stop the liberation of gas, you raise the reservoir out of the water by drawing on the pipe T.

The working of the apparatus is then automatic; the liberation of gas is slow enough

not to cause distention ; the quantity is regulated by the amount of salts employed, and patients can manage this apparatus very well themselves.

Whatever be the apparatus or method employed the principle is the same, and it now remains for us to study the application and uses of the various substances introduced into the economy by the means above described.

Bergeon, in a recent communication to the Academy of Sciences (June 25, 1887), insists on the necessity of operating with carbonic acid gas which is absolutely pure ; for if it is impure, or if it has remained a long time in the rubber bag, it loses the property of passing out by the lungs, and, accumulating in the intestine, causes meteorism and colic. As it is very difficult to purify carbonic acid, it is desirable to contrive some way of obtaining it pure at first by making use only of substances that will produce gas of a good quality.

I have already referred to sulphuretted hydrogen, and told you that since Claude Bernard's discovery we find ourselves able with impunity to introduce quite large quantities of this gas per rectum without determining toxic symptoms ; we have just repeated Bernard's experiment in our laboratory in the following way :

Taking a middling-sized dog, we injected one hundred and thirty cubic centimetres of the gas by the rectum. Test-paper moistened with acetate of lead and placed before the nostrils of the animal blackened at the end of fifty seconds, and the dog, which was not muzzled or tied, remained quiet without appearing to be at all incommoded. The sulphuretted hydrogen, then, seems to have been promptly eliminated, for a few minutes only after the end of the injection the animal's breath no longer blackened the test-paper. It is by such experiments that we have been convinced that we may without danger apply to man the injections of sulphuretted hydrogen, but with the condition that the gas shall be free from air, and that the injection shall be made slowly. Dr. Bergeon advises the use of the natural sulphur waters only, having observed that the artificial sulphur solutions are often irritant. This, however, is not necessarily the case, and the main thing is to see that the sulphuretted hydrogen is pure.

In our hospital service we use the following solutions, and according to the process given below :

I. SULPHUR SOLUTION.

R Pure sulphide of sodium, 10 grammes ;
Distilled water, q. s. to make 100 cub. cent. M.

2. ACID SOLUTION.

R Tartaric acid, 25 grammes ;
Salicylic acid, 1 gramme ;
Distilled water, q. s. to make 100 cub. cent. M.

We introduce into the glass mixing-bottle of our apparatus five cubic centimetres of each solution, a mixture capable of setting free fifty cubic centimetres of perfectly pure hydrogen sulphide ; this is dissolved in two hundred and fifty cubic centimetres of pure water, and it is through this mixture that the carbonic acid is made to pass.

I have employed the bisulphide of carbon in the form of carbon bisulphide water, whose preparation and uses I have pointed out to you in previous lectures, and especially under the head of intestinal antiseptis ;* this water may be put just as it is into the mixing-bottle.

You see that we may vary almost to an unlimited extent the number of substances capable of being absorbed by this process, but I will indicate only the principal : we have, for instance, employed eucalyptol, terpinol, iodoform, this last substance being solid was held in suspension in warm water ; lastly, we have made use of carbonic acid alone.

How has this mode of treatment been borne by our patients ? In a certain number of cases we have seen the cough diminish, the expectoration modified, and the respiratory distress abated ; some have recovered their ability to sleep and their appetite. These happy results, whenever we have obtained them, were due to the union of carbonic acid gas with sulphuretted hydrogen.

Fraentzel, of Berlin, and Statz have published through the Medical Society of Berlin the results of their observations on the efficacy of the method of gaseous rectal injections, and their results agree completely with those which I have observed.

The discussion which took place recently in New York on Bergeon's method, on the occasion when Kinnicut, Bruen, Shattuck, Pepper, Wood, Beverly Robinson, etc., gave an account of the results which they had witnessed from these gaseous injections, eventuated in conclusions which are in harmony with those which I had adopted from trials which I had personally made, and show

the superiority of the combination of carbonic acid with sulphide of hydrogen over all other antiseptic bodies.

Eucalyptol, on the contrary, has given me nothing but bad results in these rectal injections. I have always seen patients grow worse after its employment; there has been an increase of the irritation under which they were suffering, and lessening, if not complete disappearance, of appetite. Terpinol has seemed to me superior to eucalyptol, but yet inferior to hydrogen sulphide.

It has seemed to me, in the conditions in which my trials with this agent were made, that iodoform did not amount to anything, and I judge that it is absorbed in too feeble quantity to have any real antiseptic effect.

You know, moreover, that if the antiseptic action of iodoform is incontestable, its anti-tuberculous action is, on the contrary, disputed by some authorities, and especially by Rovsing, of Copenhagen, who has shown that in giving experimental tuberculosis to animals by intraocular inoculation, the course of the disease is not at all hindered by the combination of considerable quantities of iodoform along with the inoculation material. At the same time these facts have been contested by Bruns, who, in a recent communication to the Congress of German Surgeons, endeavors to show by direct experiments made on tuberculous abscesses that the action of iodoform is both specific and antibacillary. This is, however, a question still unsettled, and to be decided by future study. With regard to the action of carbonic acid when used alone, it has seemed to me to play the part of a sedative of the nervous system.

But before concluding this topic I wish to call your attention to a fact noticed by my colleague, Chantemesse, and which we have verified many times in our practice. Even in patients that manifested a marked improvement, we have not been able to note any change in the approximate number of tubercle-bacilli in the sputum. This is a fact to be remembered, showing, as it does, that if by the employment of gaseous rectal injections we may be able to improve the condition of our patients, the cause and the germ of the disease have escaped the action of the medicament.

It remains for me, gentlemen, before finishing this lecture, to speak to you of a new and very interesting method, which was first employed in pulmonary antiseptis. I refer to hypodermic injections with a mineral-oil basis. I speak of this method here because its first applications were made with a reference to the

subject which especially occupies us at this moment; but it is, as you know, of much more general application, and which has given to hypodermic medication a surprising and unlooked-for extension. One drawback of the hypodermic method, in fact, was its inapplicability the moment we wished to utilize substances little soluble or at all irritant, hence the desideratum of some such vehicle as we have now found; and, thanks to the employment of *liquid vaseline*, we may now inject under the skin substances which are highly irritant, such as eucalyptol, sulphide of carbon, and iodoform.

First pointed out by Pierre Vigier as applicable to hypodermic injections, it was my colleague, Balzer, who, in his service at the hospital Lourcine, was the first to utilize liquid vaseline as an excipient for subcutaneous injections of the salts of mercury, both soluble and insoluble. Shortly afterwards Dr. Albin Meunier, of Lyons, published a series of formulæ for hypodermic injections with a basis of liquid vaseline holding in solution various antiseptic substances, and he announced that these solutions might with impunity be injected under the skin, and without provoking any inflammatory accidents. At my request Dr. Albin Meunier sent me his products, and I was able to note in my practice the reality of his assertions. At the present time this method is actually in vogue, and is a part of current practice. It has already been in my hospital the subject of interesting researches, among which I may cite the studies of De Ley,* and of my pupil Caravais, who has made it the theme of his inaugural thesis.†

Let us inquire into this subject of liquid vaseline, for it is important to have a clear idea of what, in medical usage, we are to understand by the term. The petroleums have a variable composition according to their origin, and those of America are not comparable with those of Caucasus, or even those obtained from Europe. This variable composition explains why the petroleums do not furnish identical products on distillation. In distilling petroleum you obtain, between the temperature of 40° and 200° C., and even higher, variable bodies which are utilized in the arts. At first the petroleum ethers come over, which are so much employed to-day in our laboratories, then the illuminating oils,

* Ley, "On Antiseptic Hypodermic Injections with a Basis of Mineral and Vegetal Oil in the Treatment of Pulmonary Complaints" (*Bull. de Thér.*, t. cxii. p. 246).

† Caravais, "A Study of Liquid Vaseline as a Vehicle in Hypodermic Medicine" (*Thèse de Paris*, 1887).

and lastly, towards the end of the operation, we obtain paraffine and a liquid substance which is employed in the arts for machine oiling. It is this substance, purified and decolorized, which Albin Meunier has employed for subcutaneous injections, and which, according to the quantity of paraffine it contains, has a density between 0.810 and 0.870. This substance, which is liquid, of thin, syrupy consistence, ought, for official uses, to be absolutely neutral in order to be readily tolerated by the tissues. It dissolves a great number of bodies, and in particular, chloroform, bromine, iodine, iodoform, sulphide of carbon, myrthol, eucalyptol, terpinol, hydrogen-sulphide, etc. Bocquillon, moreover, has given us a very complete list of formulæ for hypodermic injections having for their vehicle liquid vaseline, a list which I have reproduced in my "Formulary."*

It was important, for the benefit of medical practice, to decide on a name for this new substance. While recognizing the fact that the word *liquid vaseline* is improper, since the substance recommended under this name by Albin Meunier is not vaseline, it has seemed to me to be best to keep this name, which was given by the discoverer; and if you say in your prescriptions *medicinal liquid vaseline*, you will sufficiently indicate the conditions of purity and of neutrality which the product ought to have. It was necessary to decide this point, for there exist in commerce certain so-called "liquid vaselines" which are only mixtures of petroleum and of vaseline, and which, even when tolerably pure, may give rise to very serious inflammatory accidents, as we have had occasion to find out.

The mineral oils do not alone possess the property of dissolving the different substances of which I have just spoken, and you can use in the same way the oils of earth-almond (*Arachis hypogæa*), and even olive and linseed oils, taking pains first to sterilize them by heating.

It remains now to state the results obtained by means of these new methods of injection in pulmonary antiseptis. I should have told you before that these liquids are admirably borne by the economy, and rapidly diffuse themselves through the organism.

Sulphuretted hydrogen and bisulphide of carbon seemed at first to produce good effects, but this salutary action did not long continue,

and these medicinal agents give much less favorable results when administered in this way than when given in the form of gaseous rectal injections.

Iodine works well in the forms of tuberculosis with abundant bronchial secretion; it rapidly diminishes the cough, expectoration, and oppression. It is especially in the employment of eucalyptol that this method has rendered us real service. This is the formula proposed by Albin Meunier:

R Pure eucalyptol, 5 parts;
Medicinal liquid vaseline, 20 parts. M.

I have modified this formula, and now make use of solutions of equal parts. When the eucalyptol is perfectly pure, injections of a solution of equal parts of eucalyptol in vaseline, in the dose of a syringeful (one cubic centimetre), and repeated night and morning, never cause any local irritation.

Roussel, of Geneva, who is the most ardent advocate of injections of eucalyptol in the treatment of tuberculosis, and Professor Ball, in a communication made this year to the Academy of Medicine, have reported the results of trials made in their respective hospitals with eucalyptol injections. In one case, the bacilli had disappeared from the sputa of a phthisical patient. In the reply which I made to the communication of Professor Ball I showed in this connection that eucalyptol acts only on the bronchial element, and that in certain cases of phthisis, attended by much fever, it is rather dangerous than useful. This view has been confirmed by a great number of my *confrères*, and in particular by Bouveret and Péchadre, of Lyons, Laplane, of Marseilles, and Biot, of Macon, who have come to conclusions absolutely conformable to those which I had laid down, and of which the following is a *résumé*:

Eucalyptol is generally well borne by patients; at the same time it presents certain disadvantages. Some complain of the disagreeable and persistent odor of the breath, a result of the exhalation of eucalyptol by the lungs; in others, the diminution of expectoration brings on dyspnoea. Eucalyptol is, then, chiefly a modifier of the bronchial secretions, and is in no sense a specific against tuberculosis; in fact, in all the researches which we have made, we have never seen disappear from the products of expectoration the characteristic bacilli, and if injections of eucalyptol give relief to patients, they do not cure the disease.

Nevertheless, this way of administering

* Bocquillon, *Mem. et Bull. de la Soc. de Thér.*, 1887; Dujardin-Beaumetz, "Formulaire de Thérapeutique," 1887.

eucalyptol ought to be retained in therapeutics, for when in pulmonary phthisis we can lessen cough and expectoration, and restore to our patients appetite, and with appetite strength, we have done them an inestimable service, and this is a part of our duties as practitioners, which we have no right to make light of in the treatment of a disease whose daily victims are so many.

Continental physicians seem of late to have come back again to the method of inhalations, which had almost been abandoned, and I shall here merely refer to certain new processes, which tend to show that this method may in many cases give good results. Dr. Hue, of Rouen, has experimented in pulmonary phthisis with inhalations of boiling aqueous solutions of picric acid. The results thus far have been encouraging, but too meagre to warrant us in as yet formulating a definite judgment as to the efficacy of these inhalations. I would call your especial attention to the experiments which have this year been going on in our hospital with the atmometer of Professor Jacobelli, of Naples,* and the recent trials with inhalations of sulphurous acid.

Professor Jacobelli, who has before made known to the French medical public his method of caustic inhalations, had the extreme kindness to come from Naples with his new apparatus, which for the past two months has been operated under his direction in our hospital. What has hitherto been lacking was precision in the methods of inhalation, but Dr. Jacobelli has admirably succeeded in meeting this want by his atmometer, which I now show you.

This apparatus is composed essentially of a perfectly tight cubical glass box, whose capacity is accurately gauged; this capacity may be increased or diminished at will by moving back and forth a glass diaphragm, which plays in an air-tight mortise; a scale registers the amount of displacement of this diaphragm. A number of taps afford communication with this cubical box by means of attachments of rubber tubes, some of which end in mouth-pieces, and some simply connect different parts of the apparatus with the central chamber. The whole rests on a flooring, and is light enough to be easily transported from place to place. One quite ingenious feature of the atmometer is the valve placed at the extremity of the inhaling tube; this valve enables the patient to inhale the medicinal substances contained in the atmometer, but obliges him to expire in free air. To this part of the atmometer are adapted a pneumodynamometer, a thermometer, and a pneumetrograph, apparatus which indicate the force of respiration, the

temperature of the inspired air, the quantity of air which enters at each inspiration, and even the number of inspirations.

With the atmometer we may use vapors, medicinal powders, and pulverized liquids. When it is desired to subject the patient to the vapor inhalations, the operator brings into use a closed iron cylinder, which is heated by a spirit lamp, and communicates with the interior of the cubical box of the atmometer. A graduated funnel enables one to gauge exactly the quantity of liquid which is to be vaporized.

In employing medicinal powders a rubber hand-ball on one side of the atmometer is made use of; this, by successive squeezes, forces the medicinal powders into the chamber of the atmometer.

To gauge the quantity of powders thus introduced into the cubical box, Jacobelli has employed an ingenious artifice. On each of the lateral and opposite sides of the atmometer is written the word *Pulvidensimètre*. This word forms fourteen distinct images on the inner (glass) faces of the apparatus, when the chamber is free from the medicinal dust, but as soon as the powder enters the compartment, diffusing itself through the air, it obscures the images reflected on the glass sides, and they become more and more faint and disappear in proportion as the quantity of powder admitted is considerable. One can thus, by the number of images made to disappear during the process of inspiration, estimate the quantity of powder contained in the compartment.

For the atomization of liquids two air-pumps placed on the sides of the atomizer, and worked by peculiar handles, enable the operator to exhaust the air in the atmometer, and bring into use certain rubber-ball injectors of various forms and patterns. By these the atmometer is dosed with any required liquids, which the patient inhales through his breathing-tube.

Such are in brief the principal arrangements of the apparatus of Jacobelli. They have for their end to fulfil the following indications: first, to gauge as far as possible the quantity of medicinal substances in the form of powder and vapor, for inhalation, then to make of a single apparatus a vaporizer, inhaler, and atomizer. Let us now examine the therapeutic applications of this atmometer.

I shall speak here only of the results obtained in our hospital in affections of the lungs. Taken as a whole, these results have been advantageous, as you can judge by the following statement:

Ten patients were affected with pulmonary disorders; four were chlorotic; one presented marked dilatation of the stomach. The ten patients with lung-diseases were affected as follows: two were subjects of hæmoptysis, two had chronic emphysema, one gangrenous bronchitis, and five others were tuberculous.

The patients suffering from hæmoptysis had their bronchorrhagia arrested with extreme rapidity by breathing the air of the atmometer put in communication with a reservoir containing vaporized perchloride of iron. The

* Jacobelli, "On Caustic Inhalations" (*Bull. de Thérap.*, 1887, t. cxii. pp. 105 and 166).

effect of this treatment was so well marked in these two patients, and in particular in one of them whose hæmoptysis was twice arrested under the influence of these inhalations, that we could not but attribute to their use the cessation of the hemorrhage. At the same time, we ought to bear in mind the fact that in our experiments on animals, and in placing ourselves in the same conditions, we have never been able to detect the presence of perchloride of iron in the interior of the air-tubes.

In two patients affected with chronic bronchitis and emphysema, the inhalation of air charged with vapors of turpentine and iodoform dissolved in ether has produced a marked amelioration. This improvement has pertained to the expectoration and dyspnoea, which have both remarkably diminished.

In the case of the tuberculous patients who have been subjected to the inhalations of turpentine and iodoform, the gain pertained chiefly to the expectoration and cough; we noticed no lessening in the number of bacilli in the sputum. As for the fever, if in certain cases it has been allayed by these inhalations, in others it has not been at all influenced.

Lastly, in the case of superficial gangrene of the bronchi we noticed under the influence of these same inhalations a diminution in the quantity and odor of the sputa.

As you see, Professor Jacobelli has given a notable progressive impetus to atomization, enabling us to utilize to better advantage than we have ever done before the method of inhalations. I come now to the experiments made with sulphurous acid.

It is only since the communication made to the Academy of Medicine, March 8, 1887, by Dr. Solland, that the attention of the medical public has been called anew to inhalations of sulphurous acid. In his paper Dr. Solland reports the radical cure of a case of pulmonary phthisis as the result of a prolonged sojourn in a sulphurous atmosphere. The patient was a man, 26 years of age, sergeant in a regiment of marine infantry at Cherbourg; this man was manifestly tuberculous, and his sputa contained a great number of Koch's bacilli. Placed in charge of some workmen commissioned to disinfect the wards of the hospital of Cherbourg by the combustion of sulphur, this sergeant derived so much benefit from the inhalations of sulphurous acid in the lung-troubles from which he was suffering, that he continued to sojourn a long time in rooms where sulphur was burning, and at the end of a certain period he was so far restored that

the bacilli had disappeared from the sputa, and the stethoscopic signs of phthisis no longer existed.

In view of this fact, Dr. Solland has endeavored to make the method of general applicability, and this is his mode of procedure: In a confined apartment he burns a quantity of sublimed sulphur in the proportion of twenty grammes per cubic metre, then he waits twelve hours and causes the patients to enter the room where the sulphur was burned, and remain there for a space of eight hours.

We have reproduced these experiments in our hospital, but under somewhat different conditions, on account of the construction of our barracks, which give a too ready escape to the sulphurous acid. We first burn five grammes per cubic metre, then ten, then fifteen, and finally twenty grammes, and two hours afterwards we introduce into this room our patients, who sojourn there four hours. Under the influence of this treatment we observe a speedy change in the expectoration, the cough diminishes, and the patients sleep much better. These experiments are still too recent for us to be able as yet to pronounce a definite judgment as to the utility of these inhalations; they seem, however, to be perfectly harmless, and not to provoke hæmoptysis, as at first we feared they would. Among the patients under experimentation I have, in fact, chosen certain persons who had been much subject to hæmoptysis, who have not seen their hemorrhages return under the influence of these inhalations.

Dr. Auriol, of Bellegarde du Gard, having noticed in workmen who are constantly exposed to the fumes of burning sulphur the beneficial action of these inhalations in pulmonary affections, has treated seventy tuberculous patients by this method, and has observed several cures, and in every case amelioration.

If you desire in your private practice to repeat these experiments with sulphurous acid inhalations, I advise you to proceed in the following way: Select a room of small size; take its exact cubic dimensions, stop the chimney, and close the windows and doors; then burn a quantity of sulphur, which you can make to ignite by means of alcohol poured over its surface; begin with small quantities, as five grammes per cubic metre, and increase every day by five grammes to twenty grammes. Two hours after the completion of the combustion admit your patients into the room, and let them remain there four hours.

While we were experimenting with these inhalations, one of our licentiates, M. Villi,* found another very ingenious mode of introduction of sulphurous acid. Recalling to mind that medicinal liquid vaseline had already served as a vehicle for sulphuretted hydrogen in subcutaneous injections, he conceived the idea of utilizing this liquid vaseline for the introduction of sulphurous acid. When you shake together sulphurous acid and liquid vaseline, the latter absorbs a variable quantity of the gas, according to the temperature. At 8° C., for example, one hundred grammes of liquid vaseline absorb 1.30 grammes to 1.50 grammes of anhydrous sulphurous acid. It is this solution which we have employed for subcutaneous injections in our tuberculous patients, and we have thus had another series of experiments alongside of those undertaken with the inhalations of sulphurous acid.

Note, first of all, that these injections are scarcely at all painful, and are never accompanied by phlegmons, even when five cubic centimetres of this solution are injected at one time. These injections must be made in the place indicated by Smirnoff,—namely, the hip muscles of the retro-trochanteric fissure.

The results obtained have been the same as those which attended the inhalations of sulphurous acid, but with much diminished intensity; and it is always the change in the expectoration, the lessening of the cough, and the production of more natural sleep, that patients insist upon as a consequence of this treatment.

What becomes of the sulphurous acid thus introduced under the skin, and under what form does it enter the blood? How is it eliminated, and what is its mode of action? These are questions for whose solution we have undertaken a series of physiological experiments, which you will find described in the thesis of my pupil Dr. Darieix.

As for the future of these inhalations, this is quite uncertain, and we shall not be able to pronounce positively on this subject till a sufficient number of facts have been obtained to justify formal conclusions.

I have now completed what I wished to say respecting the new antiseptic methods, and have, I think, sufficiently indicated the promise of future advantage held out to us in this direction, as well as the great extension of therapeutic resources likely to accrue therefrom.

* Villi, "On the Employment of Sulphurous Acid in Hypodermic Injections" (*Bull. de Thérap.*, t. cxiii., 1887, p. 132).

CONTRIBUTION FROM THE LABORATORY OF
EXPERIMENTAL THERAPEUTICS, UNIVERSITY OF PENNSYLVANIA.

THE PHYSIOLOGICAL ACTION OF CIMICIFUGA RACEMOSA.

BY RANDALL HUTCHINSON, A.M., M.D.†

SOME of the preparations of cimicifuga have been more or less extensively used by both regular and eclectic practitioners for the past fifty years; yet no accurate study of the drug has ever been made, save that which clinical experience alone has taught us.

On what its remedial properties depend has never, so far as I can learn, been isolated. Two resins, an acid principle (which is possibly an alkaloid), starch, tannin, gum, and a volatile principle have been found in it. The latter, Dr. George B. Wood thinks, is the active principle, since the drug deteriorates by keeping.

When 90 minims of the officinal fluid extract were hypodermically injected into the side of a healthy male rabbit (weight, 2½ pounds), the chief symptoms noticed, after fifteen or twenty minutes, were those of a sedative and quieting agent, the rabbit manifesting a disposition to sit in one place, being unwilling to move around unless made to do so, and when taken up in the hand did not struggle nor endeavor to free itself, but remained passive and quiet even when laid on its back. There was no motor paralysis. The respirations were noticed to become somewhat slowed, and the pupils slightly dilated.

Turning now from this simple experiment on the rabbit to the frog, we find, when a sufficiently large quantity of the drug (30 minims) is injected into the posterior lymph-sac of a moderate-sized frog, in a few minutes symptoms of apparent motor paralysis come on, so that the frog will lie passively on its back, with its limbs extended and perfectly relaxed. At the same time it is noticed that the batrachian rapidly becomes cyanosed, and that there is a progressive failure of the respiratory movements.

When the frog was fully under the effects of the drug, neither direct irritation with a needle nor burning of its feet elicited any response of pain or motion.

It was proven that this paralysis was not due to an implication of the motor apparatus by the fact that the frog possessed the power

† Resident Physician, Philadelphia Hospital.

of voluntarily drawing up its limbs till the point of death.

When the sciatics of the paralyzed limbs were exposed and galvanized by a current from a single cell of a small battery, we got the usual response in the tributary muscles. It was further shown, by the tying of the artery of a frog's leg close up to the body, thereby protecting that limb from the direct effects of the drug on its nerves and muscles, and injecting the drug as above, that the paralysis came on in that protected leg *pari passu* with the unprotected parts, proving that this paresis was not due to a peripheral or trunkal nerve influence.

That these experiments were correct was also shown by the non-appearance of the above symptoms of loss of reflex action and paralysis when an artery was tied and the drug injected directly into the protected limb. From these experiments, carefully repeated, it would therefore seem that this drug, cimicifuga, is a direct sedative, and in large doses paralyzant, to the frog's spinal cord, exerting its dominant effect on the receptive centres or the afferent nerve apparatus, and perhaps, to a limited degree, on the efferent nerves.

On the circulation the action of cimicifuga is a decided depressant, a fact which was strongly pointed out by the clinical evidence of Dr. N. S. Davis (*Trans. Am. Med. Assoc.*, vol. i. p. 351, 1848), and also by Dr. F. N. Johnson (*Reports N. Y. Hospital*), and confirmed by the following experiments.

When the cut-out frog's heart is thrown directly into the undiluted preparation its beats are decidedly slowed, and after a few contractions it is stopped in diastolic arrest; yet when removed, if it has only remained in the solution for a minute or two, seems capable of responding to direct stimulation.

When the drug is dropped upon the exposed frog's heart *in situ* it seems to act, so far as the eye can discern, in a similar manner, stopping that viscus in diastolic arrest.

From these experiments, carefully repeated, it would seem to be conclusively proven that this drug, cimicifuga, has a direct depressing action on the frog's heart, acting either on the cardiac muscle or on its contained ganglia.

The experiments made on the higher animals,—the dog and rabbit, for example,—which now followed, show that the drug seems to affect the mammalian circulatory system in much the same manner as that of the lower forms of life.

It is evident from the accompanying tables,

taken from the tracings of the kymograph, that when a sufficiently large quantity of this drug is thrown directly into the circulation (jugular vein) it causes the arterial pressure to fall and the force and frequency of the pulse to be diminished.

The following table of tracing, as taken by the kymograph, on dog (weight, 15 pounds), shows fall in blood-pressure and slowing of pulse-rate after injection of drug into jugular vein. Dog afterwards killed.

Time. A.M.	Drug.	Pressure.	Pulse.	Remarks.
11.45	166-176	158	
11.45.10	5 c.c.	164-170	158	Injection begun.
11.45.20	166-130	162	Injection ended.
11.45.30	120-88	130	
11.45.40	84-102	126	
11.45.50	102-140	102	
11.46	140-146	108	
11.46.10	166-176	132	
11.46.20	162-164	126	

That this slowing of the heart's action is not due to inhibitory stimulation, either centric or peripheral, is proven by the fact that it takes place just the same when the vagi nerves are cut, thereby isolating the heart from its inhibitory centres; neither is it due to peripheral influence, for on galvanizing the vagi, before and after injecting the drug, the relative slowing is equally as great at one time as at the other.

The following table of tracing, as taken by the cardiograph, on dog (weight, 8½ pounds), shows fall in pressure and reduction in the pulse-rate after injection of 2 c.c. of drug into jugular vein, and after section of both vagi nerves. Dog afterwards killed.

Time. P.M.	Drug.	Pressure.	Pulse.	Remarks.
4.45	134-108	150	Vagi nerves cut.
4.45.10	2 c.c.	136-104	144	Injection begun.
4.45.20	130-66	120	Injection ended.
4.45.30	76-112	102	Respirations very slow and shallow.
4.45.40	116-144	120	
4.45.50	130-154	120	Dog struggled.
4.46	120-146	138	
4.46.10	104-122	132	
4.46.20	102-116	132	

The slowing must, therefore, be due to a direct action of the drug on the cardiac muscle or its contained ganglia. This fact is also in direct accord with its action on the isolated frog's heart.

To explain the fall in the arterial pressure is not so easily or satisfactorily done.

Here the question arises, Is the fall in

pressure due to the diminished cardiac rapidity and force? Undoubtedly this is a most important factor in the primary fall, but does not, I think, account for the continued low pressure after large doses have been administered.

Indeed, the following experiment would seem to show quite clearly that the depressed heart does not alone account for the lowered arterial pressure, but that the vaso-motor system is depressed or paralyzed by the administration of large doses.

Injected 10 c.c. of the pure fluid extract directly into the circulation (jugular vein) of a small-sized dog (weight, 22½ pounds); almost instantly the pressure fell to within a few millimetres of the abscissa line. After two or three deep respirations the respiratory movements ceased, the pulsations of the heart became slower and slower and more labored, but it continued to pulsate for some seconds after the respirations had ceased. Yet during this period of asphyxia there was no rise in the arterial pressure, proving that the vaso-motor centres must be in a state of paralysis, and not capable of responding to the asphyxial stimulus.

From these experiments it is indicated that the diminished arterial pressure is due, first, to the direct depressing action of the drug on the heart itself; and, secondly, when in large doses, to the combined action on the heart, and a paralyzant to the vaso-motor centres at the base of the brain.

On the respiratory system large doses of *cimicifuga* lessen the number of respirations per minute, causing them to become slow and shallow, altering the rhythm, and finally stopping them completely, while the heart continues to pulsate for some seconds. Since these phenomena occurred equally after section of the vagi, they must be due to the action of the drug exerted upon the respiratory centres at the base of the brain.

When full therapeutic doses of the drug are taken into the human system, it produces a sense of fulness of the head, giddiness, intense frontal headache, dimness of vision, and vertigo, with a feeling of general malaise and aching of the limbs.

The reduction in the force and frequency of the pulse is, according to Dr. N. S. Davis (*Trans. Am. Med. Assoc.*, vol. i., 1848), a constant symptom after the administration of *cimicifuga*.

In some instances it causes nausea and vomiting, some looseness of the bowels, and occasionally purging.

TEREBENE FOR THE RELIEF OF DYSPNŒA.

By D. M. CAMMANN, M.D., NEW YORK.

TEREBENE in a general way may be said to possess properties similar to members of the group of terebenthinates the healing effects of which have so often been vaunted in the treatment of bronchial affections and diseases of the lungs. It is prepared by the action of sulphuric acid upon oil of turpentine. It is less irritating when applied to the skin or taken internally than oil of turpentine. In many cases it at first increases secretion from the bronchial mucous membrane, but almost invariably in a few days, and usually at once, it causes a diminution of bronchial secretion. Dr. Murrell, of London, has proved that in the proportion of one to five hundred it checks, and of one to one thousand prevents, fermentation, and from these experiments he proposes it as a remedy in emphysema, flatulence, etc. Articles by Murrell* and Suckling† speak favorably of its use. In a paper by myself, read before the New York County Medical Society (*N. Y. Medical Record*, October 8, 1887), its use in diseases of the lungs is strongly advocated.

The symptom upon which terebene seems to have the most marked effect is dyspnœa. This is probably due partly to a stimulating action on the heart and to a contraction of the smaller blood-vessels, partly to astringent properties and diminution of the secretion from the bronchial tubes, and partly to the relief which it affords to the flatulence with which so many of the patients suffering from emphysema and other forms of lung-trouble are afflicted, and thus allowing full play to the diaphragm by removing pressure from below. During the past year careful histories of a number of cases have been kept for me by Dr. W. L. Carr in which terebene has been prescribed. Some of the cases have already been published. I give some additional cases below:

CASE I.—Emphysema; George N., æt. 38, cigar-maker; November 23, 1886; his family history is good.

Present History.—From twenty-six years of age had a winter cough; when twenty-eight was coughing, and expectorated about a half-cupful of dark blood; coughed after that, but expectoration was not bloody; after

* Murrell, "Pure Terebene in Treatment of Winter Cough" (*Brit. Med. Journal*, December 12, 1885).

† Suckling, *Ibid.* (*Brit. Med. Journal*, March 20, 1886).

three days spat up a little more blood; no pain in chest; no fever; expectoration was quite free; sputa dirty; did not lose in flesh; thinks that he grew stouter. Since then has coughed more or less, winter and summer; always more in winter; expectoration has sometimes been streaked with blood, but he has never had profuse hæmoptysis; for the past few days has expectorated "lumps of blood"; some soreness on left side.

Present Condition.—Well nourished; no fever or sweats; dyspnœa on exertion, but not otherwise; never at night; coughs most in the morning; expectoration not always easy; sputa generally yellowish-white; some pain on left side, in mammary region; appetite good; bowels not quite regular.

Physical Examination.—Chest well developed, and thickly covered with adipose tissue; pulmonary resonance on percussion; harsh respiration under both clavicles and at both bases behind; expiration a little longer than inspiration over both lungs; respiration feeble at bases of both lungs in front; coarse râles at bases of both lungs in front in axillary and infrascapular regions; right side, in front, cog-wheel respiration. *Rhus aromatica*, ℥ xx q. i. d.

November 27.—Expectoration this morning was blood-stained, afterwards thick with blood. Since last entry expectoration and cough somewhat increased; thinks that he took cold just before beginning the use of the *rhus*; some pain in left side; appetite and bowels good; urine free and more in quantity.

November 30.—Hæmoptysis still continues; urine increased in quantity; appetite improved; cough less frequent. Discontinued above and gave terebene, gtt. xv q. i. d.

December 4.—No blood since Monday (five days); expectoration white; does not cough as much; bowels loose; appetite fair; urine about the same.

December 11.—Bowels loose; urine more free; coughs more than he did; not as much mucus expectorated; sputa dark, not yellow; pain on left side; no hæmoptysis.

December 28.—No blood; expectoration not so free,—only in the morning, not during the day; no pain; appetite fair; bowels open twice a day; urine same; thinks that he has eructations of wind after the terebene; tongue is clean.

January 13, 1887.—Raised a little blood-streaked sputa last week; still coughs in the morning, but not during the day. Terebene continued.

January 25.—Has been coughing more than usual during past two or three days; no blood; hardly any pain. Discontinued terebene; a catarrhal condition of nasal passages. Cough-mixture was ordered, maltine and compound syrup of hypophosphites.

January 29.—Catarrhal condition referred to above is better; has been troubled with catarrh during the winter for a number of years. Stop cough-mixture; R Terebene, gtt. xv q. i. d.

February 19.—Some catarrhal ozæna; coughing some in the morning; expectoration during the day; sputa yellowish and white, sometimes frothy; no blood; appetite good; bowels regular; is working three or four days a week. Maltine and cod-liver oil; terebene.

March 1.—Hæmoptysis last night; blood not very much; no cough in the morning; shooting pains in chest.

CASE II.—Bronchitis and asthma; Margaret M., æt. 45, washerwoman; February 1, 1887.

She has had muscular and subacute articular rheumatism. She is subject in the winter to colds. Began to be short of breath last August; now she is short of breath on exertion and when lying down; cannot sleep except in a chair; coughs most in the morning; expectoration after a long paroxysm of cough; sputa white, sometimes frothy; pain in chest and between shoulders; is feverish and at times has profuse perspiration; appetite fair; bowels not regular. She gives a history of asthmatic attacks, and physical examination shows the presence of bronchitis.

Treatment.—Terebene, gtt. x q. i. d.

March 15.—Much improved; condition generally better; dyspnœa and cough less; expectoration easier; urine free; bowels moved with pills. Terebene increased to ℥ xv, in mucilaginous mixture.

March 22.—Breathing easier; don't cough, except a little early, when waking; expectoration easy, and sputa white; appetite fair; bowels regular; urine clear and free; eructations after taking the medicine.

CASE III.—Phthisis pulmonalis; Carrie W., æt. 25; May 5, 1887; her father died of heart-disease at the age of 28.

Previous History.—Says she had pneumonia five years ago; did not have a doctor, but was examined at a dispensary; had never had any cough before that time. Once in a while after that she would expectorate blood-stained sputa. Used to have a cough almost all the time, but generally most in March. She has had four children; three died in infancy.

Present History.—She had a severe hemorrhage on March 2; cough was severe and expectoration difficult, with bloody sputa; "had pain in chest and around heart;" had fever, but no chills; heavy sweats, diarrhoea, and vomiting. She coughs most in the morning and at night when lying down; cannot rest well on the left side; is short of breath on exertion and in the morning; sputa thick and yellow; pain in right side; no night-sweats or fever; feels exhausted; has lost in flesh; appetite poor; bowels regular; menses irregular and scanty. R Terebene, ℞ xv q. d. in mixture.

Physical Examination.—On percussion, dullness under right clavicle. On auscultation, bronchial breathing and bronchophony under right clavicle; harsh respiration over both lungs in front, most marked under left clavicle; feeble respiration at both apices behind; harsh below; coarse râles at right base behind.

May 7.—Cough is easier; sputa are thin and watery; breathing is easier, and she can sleep much better; little pain in right side; bowels regular; urine about the same.

CASE IV.—Phthisis pulmonalis; Elizabeth K., æt. 36; May 12, 1887. Her family history is good. Last May she had a cold, and the doctor told her she had trouble in the lung; had cough and fever; no pain in chest; no hæmoptysis; had laryngitis, which began in November, 1886; night-sweats; emaciated; now she has some cough, with yellow expectoration; sometimes has night-sweats; has lost in flesh; appetite fair; sometimes has pain in left lung; yesterday for first time had hæmoptysis; lost quite a good deal of blood. R Terebene, ℞ xv q. i. d. in mixture. She was also given the compound syrup of the hypophosphites and cod-liver oil.

Physical Examination shows consolidation at the left apex and a good deal of pleuritic exudation in the left side; some fluid in left pleural cavity.

May 21.—Less dyspnœa; cough less; sputa diminished and yellow; urine same; sputa bacillated.

June 2.—Dyspnœa and cough less, and sputa diminished in quantity. She coughs, however, at night about as much as formerly.

Terebene is not disagreeable to take, and I have not found any difficulty in having my patients continue it for several weeks or even months.

Only after a considerable time and its use by a number of observers should a drug be received as a useful member of the Pharma-

copœia. Terebene bids fair at present to earn its right to occupy such a place.

19 EAST THIRTY-THIRD STREET, NEW YORK.

CURIOSITIES OF THERAPEUTICS.

BY G. ARCHIE STOCKWELL, M.D., F.Z.S.,
PORT HURON, MICH.

(Concluded from page 669.)

V. PSYCHO-PHYSICAL EVOLUTION OF MEDICINE.

FROM the stand-point of the vulgar masses essences that "walked not in the light"—that is, were unresolved—were supposed to seek opportunities to re-enter upon mundane existence, even in inferior station or capacity, in order to work out the expiation that would permit permanent unity, or *Perfection*, with the Supreme. From this, with the Buddhistic branch of Veda-Brahmism, arose the doctrine of Transmigration,—an exoteric explanation wrested from the priesthood in the same manner as the purgatorial confession of the Romish Church was obtained from Gregory the Great.* This was a matter of state polity, and subsequently elaborated in order to perpetuate esoteric tradition, and to embrace the so-called metempsychosis of Gautama,† to which was added the conceptions of the vulgar of future places of reward and punishment as derived from esoteric references to the ordeals and initiations of the Colleges.‡ A wandering unresolved spirit of

* In the popular belief of Middle-Age Christianity, St. Peter sat as a doorkeeper at the gate of Heaven: to him it had been given to "bind or loose," consequently he denied or admitted the spirits of men in consonance with his own pleasure. This, however, was a power many (even among the priesthood) were disposed to deny, as being anticipatory of the "Judgment," which would thus be rendered nugatory or needless. Soon arose a demand similar to that now agitating one of the orthodox sects of the religious world,—a demand for a period of probation, and resting-place for departed spirits,—which was met in the latter part of the thirteenth century by Pope Gregory granting a "place of purgation,"—*Purgatory*.

† According to tradition, Buddha has appeared, or eventually will appear, upon earth twenty-two times, in some mundane form: and this metempsychosis, by vulgarism, has been extended and multiplied to one thousand, of which more than six hundred have been accomplished.

‡ It must be remembered, like all religions, Christianity was *Mystical* in its early days. Primarily *Mystery* had a different signification from that now attached to the word: it was equivalent to *Instruction*. Baptism,

evil, chancing to encounter another and weaker in possession of a mundane economy, *might* usurp the place of the latter, and thus obtain temporary relief, the latter being forced to accept the burdens of the former. As a sequel of such belief and teaching,—a teaching perfectly in consonance with the primitive condition of the uneducated mind,—the ill, insane, feeble-minded, epileptic, etc., exactly as is true among savage and Oriental races of to-day, were deemed holy,* and regarded with superstitious awe as being invested with emanations from the supernatural world. Syncope, like ecstasia and delirium, was in some measure separation of the soul from the body, or the overthrow of the material essence by contending spirits, or perhaps a temporary summoning thereof into the "Awful Presence" for purposes known to the latter alone: and by the *Koran*, and unwritten laws of barbarism, those stricken with any form of mental insensibility or rapture are not to be interfered with, lest the act tempt the displeasure of the spirits or Supreme to the

sacrament, confirmation, eucharist, "The Lord's Supper," all are acts and formulæ derived from the *Mystikos Sekos*, or Colleges of antiquity, and all, even as late as the fourth and fifth centuries, were termed *Mysterries* by Christians. So, too, the passion plays, intended for popular instruction, bore like name. (See McClintock and Strong's "Biblical, Theological, and Ecclesiastical Cyclopædia," vol. vi. p. 785.) From the scenes exhibited in celebrating the *Mysterries*, and in their initiations, were copied the anthropomorphic ideas that even yet obtain regarding heaven and hell. During the ordeals a candidate yielding, was suddenly plunged into deep and dark subterranean chambers, from which, if he issued alive, it was at the expense of his reason. An excellent and vivid description of these "dark abodes," and of the tortures of probation, occurs in an old French romance of the last century, entitled "The Life of Sethos." These chambers, in partial state of preservation, have been discovered by modern explorers: and at Uxmal, in Yucatan, in an artificial mound of peculiar construction, known as the "House of the Dwarf," such exist in their almost original perfection, their ceilings forming triangular arches, a shape adopted undoubtedly in accordance with certain Mystical teaching (esoteric), since circular arches exist elsewhere. These arches are the counterpart of those described by Enoch, the apices of which are stones engraved with mirific characters. (See THERAPEUTIC GAZETTE, August, 1887, p. 541, Appendix N.) The same arch is found in the Chaldean tombs at Mughier; in the centre of the great pyramid of Ghizeh, in Egypt; in the most ancient monuments of Greece (the treasure-room at Mikene, and in the tombs of Etruria, etc.), Persia, and Petra.

* Everywhere in the Orient the mentally afflicted are deemed *sacred*. Epileptics, like those from whom Jesus of Nazareth "cast out devils," are frequently inclined to claim for themselves holiness. See Ireland's "Blot on the Brain," p. 40.

detriment and undoing of those meddling.† Such is the origin in part of various orders of religious mendicants and devotees; and in this also we see a yielding on the part of knowledge to meet the demands of primitivism, which assigns spirits to all things, and requires an essence for the inert and inorganic as well as the vital and organic.‡ Among other esotericisms, some of which yet obtain in various guises in the midst of the highest civilization, we find various spirits permitted to serve as attendant sprites for the warning, torment, and torture of the embodied evil of earth, whereby they work out their own expiation:§ this is the original doctrine of familiars, ghosts, *lares*, *manes*, etc. But for the most part, essences, whether temporarily or permanently separated from the mortal clay, if not within the pale of Perfection, are condemned to walk in "outer darkness," tortured by inability to return or Perfect,|| until such a time as they shall have attained the purity that will enable them to encompass one or the other of the desired ends. Ultimately, however, Perfection will result, at the period of final restitution that must overtake all things, when they will be merged into that whence they were derived,—the Infinite.

The usurpation of the corporeal form was *prima facie* evidence of imperfection and inharmony on the part of the individual body and its vivifying essence,—an inharmony that by the Masters of the *Mystai* was recognized as amenable to influences developed from or through the Infinite Intelligence—biologic force—in proportion to the ability of the operator, and faith upon the part of the operated. Knowledge of this force, as had through Mystical education, was prompt, certain, and sure in its phenomena, though not perhaps in its effects; but when such power was derived from inharmony, or interrupted

† See p. 233, THERAPEUTIC GAZETTE for April, 1887; also Conjunction of *Pou-ni-ka-ma-ta* in the same for May, 1887, p. 308.

‡ Ibid., April, 1887, p. 229.

§ Says Mr. Brainerd in "Historic Incidents in India," speaking of the primitive race of *Shanars*: "Their religious ceremonials have reference to the influences disembodied spirits exert over the condition of the living. . . . These spirits are supposed not only to take up their abodes in dwellings, but also in the bodies of the living, whereby the individual consciousness and responsibility of the person possessed is supposed to be suspended." Note, too, the incident in the *New Testament* related by Luke, chap. viii. 27-30, and Mark v. 2-8; also Draper's "Conflict of Religion and Science," p. 120.

|| Matthew xii. 43-45.

through lack of familiarity with the laws governing its production and application, it was uncertain.* Familiarity with these laws could be obtained only by the long and arduous education that had for its graduation the "new birth,"—an education which even Bishop Warburton admits to have been the "nature of the phenomena concerning the secrets of the world." Hence the Nazarene, confident in his Perfected superiority as obtained through the Colleges of Egypt, familiar with the laws whereby prompt obedience is demanded of the nerve-centres, "cast out demons," healed the epileptic, relieved the palsied, and restored the afflicted to their "right minds."† That such were by no means uncommon phenomena among the *Mystai*, and deemed the reverse of miraculous save perhaps in the eyes of the vulgar, we have frequent evidences in the Old Testament and the doings of Prophets, or *Mac*, and also the testimony of Christ himself as reported in the "*Gospels*":‡

* Matthew vii. 13-24.

† Ibid., xii. 24-28.

‡ In quoting the above I have availed myself of the Greek, which, as will be seen, compares favorably with the New Version by employing the optional (marginal) notes. That the mind can make contact with other minds, and with objects we are pleased to term inanimate and inorganic, through *other* channels than the five senses, is now becoming slowly recognized. It must be remembered that of the many thousands of years of man's residence upon this earth, but a very brief period of existence, so far as our knowledge and history extends, can be claimed for inductive science; and it is somewhat absurd, though in perfect consonance with human egoism, to claim the mystery of the universe has been probed to the bottom. Professor Crookes truly remarks, "We live in a world of marvels, of which not one-millionth part has ever been guessed, much less discovered, roughly giving the title of supernatural to everything beyond our comprehension." Why mental impression—call it biologic force, or whatever you will—may be manifested at considerable distances, as yet is a problem beyond the capabilities of the human mind; but these very manifestations give evidence not only of being the reverse of the miraculous or supernatural, but of being controlled by fixed laws. Having not even mastered the alphabet of these laws, we are accustomed to judge by visual *effects* without knowledge of *cause*. That cause may have its origin in the subtle fluid man has harnessed to the electrical machine, and that is developed by the decomposition of chemical agents, is surmised. Is Life merely a factor of such decomposition obtaining generally throughout the universe? Is corporeal existence a storage-battery, so to speak, or one of many cell-factors? It cannot be denied that, under certain conditions and surroundings, individuals and animals can and do develop a force superior and entirely unlike to their muscular abilities, and that this force may be

"And if by Beelzebub I cast out demons, *by whom do your sons cast them out?*"—sons in this instance referring to the Jewish *Mystai*, for he was speaking to the Pharisees, who were all men of the Mysteries, and who sought to array the rabble against him by the assertion his power was illegitimately obtained through a mythically esoteric personage. "Therefore shall *they* (the Hebrew Colleges) be your judges. But if I in the Spirit of God cast out demons, then is the kingdom of God come among you. How can one enter the dwelling of *the strong* (of power) except he first find the *strong*? . . . Every sin and blasphemy shall be forgiven *you* men: but the blasphemy of the Spirit shall not be forgiven . . . neither in this age, nor that which is to come. Either make the tree good, and the fruit is good; or make the tree corrupt, and its fruit is corrupt: for the tree is known by its fruit. Ye offspring of

called into play through nervous inharmony and mental effort. Whence this power is derived, and where it may—or rather where it may *not*—be found, is beyond surmise, since it often, and suddenly, manifests itself in most unexpected situations. Those who have observed so-called mesmeritic and hypnotic phenomena, know that these are not obtained save at the expense of the nervous system and a waste of gray nerve-substance. May not the *Perfection* of the Mysteries, then, have been in part the means of restoring to the human battery—the nervous system—the waste expended, just as the *electrical ray* or *eel* recovers its power? If the evidence of such candid observers as Messrs. Hare, Crookes, Hallet, Stewart, Wallace, etc., may be received,—gentlemen who have no end to accomplish but scientific truth, and no interest or belief in modern Spiritualism as popularly enunciated and taught,—the removal of the bonds to a distance, as narrated in the conjurings of *Wa-ah-poos* (THERAPEUTIC GAZETTE, May, 1887, p. 311, Supplement G), is within the range of possibility, independent of trickery, though in this instance the latter was undoubtedly resorted to. It involves no phenomena that we may not see manifested in the broad glare of day by the moving of heavy articles of furniture at a distance from the operator. I have personally known a gate to be opened by lifting the latch, again closed, opened again and swung in the opposite direction, and this repeated half a dozen times in succession, the individual procuring this phenomenon meantime seated four rods away; and though muscularly the superior of the operator, my strength was insufficient to control this movement. This undesired power was a great source of annoyance to the individual in question, whose stanch orthodoxy abhorred such involuntary "coquetting with the agents of evil." He could not explain it; it came and went abruptly, and without warning, merely manifesting its return by a "peculiar tense feeling about the head," as he expressed it; and the worry resultant therefrom eventually brought him within the four walls of an insane retreat. (See THERAPEUTIC GAZETTE, May, 1887, p. 310, Appendix E.)

Vipers,* how can ye, being evil (not yet Perfected), speak good things (the truth)? For out of the abundance of the heart (knowledge) the mouth speaketh."†

Observe in the foregoing, as also in the paragraph following, a beautiful example of esoteric language, conveying reproof as well as indignation; and that the speaker not only makes his claim good to rank as an exponent of the Higher Mysteries, but wrings an acknowledgment of the fact in part from his accusers, is shown in that a moment later they concede and address him by the title of *Master*, which only accrued to those who had obtained the first of the three final degrees leading to *Perfection*! There is nothing strange that this man of foreign education should incite the enmity and opposition of the *Lab-Mac* (Chief Priests) of Jerusalem, since he was a living reproach upon their Mysteries, which had become prostituted to the most base of purposes. Listen to what he says under examination and trial for his life: "*To this end have I been born, and to this end came I into the world,—that I should bear witness of the Truth.*" Every one that is of the *Truth* heareth my voice,"—i.e., understood the meaning this esotericism was intended to convey. "Pilate saith unto him, 'What is Truth?'"‡

The Supreme being an *Æther* permeant and permeable of space, and Life and Matter alike, emanations or rather proliferations of that Ether, it was but natural the *Mystai* should hold that change in one portion of the Fluid could not take place without influencing in greater or less degree the other two, in accordance with the law of dispersion of fluids. This was the primary physiology of the ills of animality we are accustomed to denominate *Disease*, a term that etymologically expresses disturbance or inharmony; or, in other words, disease is a sequel of impression whereby are disturbed the relations existing between the corporeal and essential, or between both and the Universal Intellect. Thus the movements of planets, such as their

cycles, conjunctions, apogees, and perigees, could not be without influence upon the earth, and through it its inhabitants, in proportion to its distance therefrom,—exactly as the concentric wave-circles made by the pebble dropped into the pool disturb the equilibrium of the leaves strewn upon the surface, in proportion to the intervals,—just as the steamer ploughing through the lake washes with waves the distant beach in consonance with the law of equalization, which causes the waters to rush to supply the vacancies made by the obstructing and moving hull. Here we see another evidence of *recorded impression*. Here was the foundation of astrology, astronomy, and mathematics; and from like source was derived all scientific nomenclature,—therapeutical, nosographical, etc., besides providing titles for the various productions of earth, including the metallic bases defined by a science that itself received its baptism from the land of *Chemi* and Colleges of the Delta.§ It was discovered that the seasons depended upon solar influence,—the solstices; that other planetary movements coincided with certain arrangements of waters, growth of plants, and kindred physiographical phenomena; that the rise, fastigium, and decline of epidemics, plagues, storms, drouths, etc., etc., corresponded to certain celestial phenomena; that all things exhibited a tendency to move in cycles, even to pestilences and the artificial emanations of the human mind. Planets derived their names from those of the *Mystai* who devoted their days to the solving of problems connected with or propounded by such celestial bodies. An imperfect and empirical form of knowledge accrued to the priesthood through esotericism, whence was derived divination,|| sor-

§ Words in general employment in our own day are survivals, such as "sunstroke," "moon blindness," lunacy, saturnine, mercurial, venery, venereal, aphrodisia, urea, adonis, May, etc. Indeed, it is almost impossible to utter a sentence without some word that philologically owes its origin to the Mysteries.

|| Divination was the study of *impression* upon animals and other objects of nature, whence arose *sacrifice*, and whereby men were led to anticipate changes in the Universe by the most subtle of such impressions. It was the foundation of pathology and modern physiology. We to-day smile at the "goose-bone" and "chicken offal" predictions of old women, weather-wise men, and their ilk, and justly so, because they are mere lingering superstitions. We term them *coincidences*, but as nothing is without law, there must be a law for coincidence, which, in our era at least, escapes the human understanding. We admit, however, that animals receive impressions that are forerunners of great cataclysms or convulsions, like earthquakes, tornadoes,

* "*Vipers*," or serpents in this instance has not reference to the creature: it was a Mystical term for the lower degree of *Mystai*. It will be remembered the serpent was a symbol of Nature and of the Universe.

† Note how the Pharisees, convinced in their own minds of the authenticity of Jesus' claims, yet endeavor to weaken his influence, first by demanding a sign, then by calling attention to his supposed ignoble origin: "Behold thy mother and brethren stand without." To which he substantially replies that all seekers after *Truth* and followers of *Pathr* are brethren.—Matthew xii. 22-50.

‡ John xviii. 38.

cery, and the astrology of our history which (manifestly) is but a shadow of the real. The secrets of the *Mac* were so sacred but few, even of the sacerdotal orders, were admitted thereto,*—only those deserving of the honor; they put in practice the principle "It is necessary to keep the discoveries of the philosophers in the works of art or nature from those unworthy of knowing them," as enunciated by Roger Bacon, who was confined during many years in a prison cell by his ignorant brethren because of his erudition. The *Mac*, however, possessed of the Truth, were alike revered for their knowledge and feared for their power, and with the vulgar, as a sequel to exoteric explanations offered by the lesser priesthood, obtained a supernatural halo by reason of their supposed connection and familiarity with the Supreme. Naturally in time they came to be revered as deities; and thus arose the apotheosis, that, coming to us from vulgar sources, has been mistakenly accepted as the religion of all classes, ranks, and conditions alike. The apotheotized *Mac*, "the gods," by rea-

etc., which for lack of better reason we term *Instinct*, but which undoubtedly is due to interrupted harmony. The *Mystai* professedly understood these things, and the means whereby such evidences were recorded.

* Clement of Alexandria writes: "The Egyptians neither intrusted their Mysteries to every one, nor degraded the secrets of Divine matters by disclosing them to the profane, reserving them for the heir-apparent to the throne, and for such of the priests as excelled in virtue and wisdom." Again, if we go to Hindustan, there we will learn of a secret society of wise and learned men, whose object is the study of philosophy in all its branches, but particularly the spiritual development of man. The leading fraternity is established in Thibet; and the high pontiff and other dignitaries of the Lamaistic faith belong to it. They are known throughout India by the name of *Mahatmas*, or "Brothers." To obtain this title it is necessary to suffer a long and weary probation, and pass through ordeals of terrible severity. Many of the *Chelas*, as the aspirants are called, have spent twenty, even thirty years of blameless and arduous devotion to their task, and still are in their earlier degrees, looking forward to the happy day when they may be judged worthy to have the title of Brother conferred upon them. These *Mahatmas* are the successors of those secret societies of learned Brahmins, so celebrated for their wisdom, from very remote ages, even in India, and of whose Colleges, always built on the summit of high mounds, either natural or artificial, Alexander the Great, when he achieved the conquest of that country, was never able to take possession. Philostratus informs us that their mode of defence consisted in surrounding themselves with clouds, by means of which they could at will render themselves visible or not, and hurling from their midst tempests, fire, and thunder on their enemies. Evidently in those early times they were familiar with gunpowder or explosives of kindred nature, and made use of these to explode mines and destroy their assailants.

son of their studies of certain planets which subsequently bore their names or titles, became confounded with these bodies, and as investigators they were supposed to be familiar with all the phenomena accruing to the changes and movements in the heavens. In this way thirty-six diseases with their titles (some of the latter now obsolete) have been directly handed down to us, that philologically or otherwise are of celestial or planetary extraction (and indirectly and by combination twice as many more); and an equal number of pagan gods are found associated therewith, that to-day, rebaptized as *saints* into the Romish Church, perform for the vulgar the same offices as of yore.† It is not becoming in us to sneer at these facts, however, since our own history and tradition is for the most part made up of esotericisms and exoteric explanations thereof; and we perpetuate the same in our daily‡ relations, being driven thereto to satisfy the queries of ignorance, infancy, and childhood; and every religious body in its confession of faith, its creed, or its catechism, deals in esotericisms,§ which as explained to the vulgar, inculcate doctrines oftentimes, that are wholly at variance with those of its founders or more educated followers. It is impossible for any two minds to see or reason precisely alike, and a trifle of divergence here, as in mathematics, by prolongation may eventually secure an impassable gulf of separation. In the Latin Church we find an educated priesthood controlled by a high pontiff, but the vulgar herd that constitute the bulk of its following receive such exoteric explanations of the doc-

† "The vulgar believed there were thirty-six demons or spirits who bore the names of the planets, and who were instrumental in procuring disease." (Origen.) The Latin Church has a like number of saints, with like properties and abilities. (See McClintock's "Cyclopædia.")

‡ Almost invariably the logical mind of the child, when instructed that "God made the world" and is a general conservator, inquires, "Who made God?" when the parents are forced to take refuge in esotericisms that are esoteric even to themselves.

§ "Jesus Christ is *God*, being the Logos. Jesus Christ is *man*, possessing the normal characteristics of humanity. Jesus Christ is *God-man*, being the union of God and man in one person. Therefore Jesus Christ is the product of an incarnation; that is, according to the plan of the Father and by the agency of the Holy Ghost, the Logos took a physical body in a virgin mother." (Dr. Townsend's "Outline of Christian Theology.") It may be seen how Perfection was deemed the union of the Supreme and man in the same person, and that the Perfected, like Christ, were elevated to the rank of Divinities.

trines of the faith as are found to be best adapted to their comprehension. Truly it is folly to "Cast pearls before swine, lest haply they trample them under their feet." Yet, social polity demands the linking of humanity by bonds, in order to insure its preservation and to secure general unity of purpose. Marriage, for instance, has as its ultimate object the perpetuation of the human race; but so far as the sequel is concerned the form of the administered rite is immaterial, and but an esotericism and mystical survival. But look behind the veil into the mysterious laws of heredity, and here will be found paramount physiological reasons for the binding of the two sexes by law,—the same reasons that originally led to the high estimate placed upon virginity and female continence,—a reason that would suppress the hostile heritage of imperfection as a sequel to physically-perfected conjunction.* Superstition has made a psychical and physiological necessity of a form that, originally a true sacrament, has now lost its original significance; but its value to the world at large is none the less manifest in spite of repeated violations and lack of higher understanding.

I have endeavored in a cursory manner to show that the Mysteries, wherever found, were established for the cultivation of science, the acquirement of knowledge, the improvement of man's moral and physical nature, the development of his intellectual and mental faculties, and a general understanding and study of the laws that govern the Universe,—all of which are immediately linked with Therapeutics. The *Mystai* made of their learning and discoveries a profound secret, surrounding with mysterious and enigmatical allegories and symbols, because, says Strabo, "To surround the things that are sacred with a mysterious obscurity is to make divinity venerable,—is to imitate its nature that escapes man's senses;" or, as Gregory of Nazianze wrote to Jerome, "The *less* ignorant men understand, the *more* they admire." And so the intermediates between knowledge and vulgarity, the priests, desired to be regarded as mediators between the Perfected and man, as were the Perfected between the priesthood and the Supreme Intelligence.

The similarity of rites practised, the identity of symbols, prove that all had their origin from a common source,—a source that is a mat-

ter chiefly of conjecture. The Brahmins claim to have taught the Egyptians and Chaldeans, and it is well known that in many of their religious ceremonies they employ words that are older than the Sanskrit, and that are said to be derived from a language known as *Akkadian*, originally spoken by the peoples of the countries contiguous to the lower Euphrates.† "This," says Dr. Le Plongeon,‡ "strange as it may appear, presents many affinities with the Maya dialect, which is still the vernacular of the aborigines of Yucatan and other countries south of the Peninsula." Valmiki, in the *Ramāyana*, tells us colonists from Mayax in very remote ages settled in the Orient; it is well known there were Magi in Babylon at the time of Daniel, people possessed of special learning, speaking a strange tongue, and deeply versed in the art of prophesying, explaining dreams and prodigies, and the omens derived from the entrails of victims offered as sacrifices; and elsewhere it has been shown that *Ma-gi* and *Ma-yi* are cognate, if not identical words.§ We also know the apartment in the temples sacred to the higher initiations, whether in Mayax, India, Egypt, Arabia, Chaldea, or Judea, had the form of a rectangle,|| the form preserved for temples of worship to this day. A rectangle in the hieratic alphabet of Egypt and Mayax—and so in the ancient Chinese—is the letter M, pronounced *Ma*, a word that means not only *first*, but *place*, *country*, and by extension the *Universe*.¶ The *Mystai* adopted it, not, as has been suggested, because they believed the earth to be square or oblong, for they well understood its sphericity, but as the sign of the word *Ma*, which conveyed to their minds the precise idea that is expressed by our word *Earth*.

Undoubtedly Osiris, Horus, Isis, Apollo, Saturn, Vulcan, Mercury, Mars, and the host of other pagan deities appearing in different countries under different names, were originally real personages admitted to the Higher Mysteries, the same as Menu, Hercules, Chiron, Esculapius, etc. The history whence we derive our information is esoteric by the confessions of its authors. Allegory was the language of the Mysteries, of the books, of the

|| Exodus xvii. 18.

¶ Modern Masonry derives its word *lodge* from the Sanskrit *logia*, "Universe." This is why the lodges of M. possess their present form.

* It is a physiological fact that the first (voluntary, at least) sexual congress leaves the impress of the male upon all subsequent offspring of the female.

priesthood, of the founder of Christianity; it was employed by the Prophets and the Oracles; it is the language of the Orient to this hour, and is markedly assertive in the speech of all barbarians and primitives. It is a form of poesy, and poetic license, permissible in all ages, made more obscure by philological changes accruing to Time. There is nothing strange in the fact that the lines of Homer as handed down to us lack the fire and deep meaning of the period at which they were composed. Even older are the Psalms of David, and other Hebrew poets. The Vedic hymns are yet all but sealed books to the ablest scholars. The poems of Ossian, and Norse *sagas* recording historical incidents, are so interwoven with allegory as to meet little sympathy or favor save from a few, so little that they are often stamped as fables! Think, then, upon the difficulty of obtaining the true meaning of ancient words, doubly handicapped by esotericism and the subtleties of languages that are now obsolete; and remember also the dialect of the Canadian *Habitan*, which represents the Galic speech of only two centuries ago, is practically unrecognizable by the modern Parisian.

Science in every age and era demands support, hence in all times tithes and offerings have been required as a tribute from ignorance to knowledge; hence the system of sacrifices whereby the vulgar were accustomed to reward the erudite for instruction received,—instruction that was rendered in proportion to their capacity to receive and comprehend. If that instruction was esoteric, or exoterically rendered esotericism, it at least had the merit of corresponding to the law of demand and supply, exactly as the modern clergyman is retained or dismissed from his pulpit accordingly as his labors meet the pleasure of his parishioners. From tithes and offerings the transition to amulets, especially among the more vulgar, was simple; and even amulets are not without value from a psychophysiological stand-point, oftentimes. So, too, the therapy of the modern medical man is often, more often than is commonly surmised even by the prescriber, psychical and consequently amuletical, and that, too, in spite of supposed direct application and action. But is therapy to be abandoned because it is a source of frequent error? Who has not discovered that the same drug, in like doses, in palatable form was practically inert with certain individuals, but speedily asserted itself when administered in all its crude nauseousness? In all the masses of error there must

still be an element of truth hidden, else the error could not exist. Causes give rise to effects, yet a combination of effects may also tend to modify the cause. Physiologically and inherently we are all superstitious and affected by superstitions, only in varying degrees. We all seek to fathom the secrets of nature, yet stand in awe thereof. "Too great familiarity breeds contempt," hence from a sociological view it is well we cannot all grasp the same idea alike, and that the one great secret of life, term it perfection, future unity, or what you will, is in some measure esoteric.

Unfortunately, as we delve among the musty and forgotten records of the Past, our mental vision is dimmed and warped by association with the present, sometimes even obliterated. We see merely that our civilization is a survival and a reculture of the forgotten. The little that comes to us of the realities of the Mysteries is far from being clear, since it is impossible to separate it from modern superstition. Medicine, in some of its branches at least, has been equally if not further advanced than in our own decade. Turning to the "Flowery Kingdom," a country whose literature and history have been so little explored as to be practically unknown, we discover among the occasional liftings of the veil of obscurity the fragments of intellectual monuments of stupendous grandeur, no way behind those of Mayax, India, and Egypt.

There are abundant reasons for surmising the Celestials were anciently possessed of greater knowledge of physical, mental, and medical sciences, including pathology, than at any period of their history familiar to our civilization. Thirty-one centuries before the Christian era the emperor Chen-nong was the author of an extensive treatise that embraced Therapeutics, Materia Medica, Pharmacy, Anatomy, Physiology, Histology, and Biology. In this work remedies were classified according to their action and properties, and in accordance with a primary division into pyretics, antipyretics, and febrile neutrals. The same distinguished author is also said to have discovered the counterpoise of the earth, which by some is supposed to have reference to the action of gravity.* Four centuries later, in the reign of Hoangti, sometimes denominated the "Yellow Emperor," the phenomenon of the circulation of the blood attracted the attention of the learned, becoming a subject of exhaustive investigation

* Probably this is esoteric, and refers to certain doctrines of the Mysteries.

and experiment, carried on in part by the aid of condemned criminals, and partly by researches in comparative physiology. The results are to be found in the surviving remnants of the *Soo-Wan*, or "Disquisitions upon Health and Disease." The John Hunters of this era appear to have been the emperor himself,* and three members of the Imperial household, designated as Ky-pe, Yen-fou, and Ley-king, and it is affirmed that science was in such an advanced stage of perfection that "the remedy requisite to the relief of every ill and condition of humanity was known, and men lived out their allotted days in consonance with the intent of Nature."

From 2207 to 248 B.C., a period embracing the *Hya*, *Shang*, and *Chen* dynasties, a vast number of medical works were published, some of which, or fragments thereof, are still extant, and religiously preserved among the archives of the Chinese Empire. One of these fragments, known as *Nan-king*, and accredited to the eleventh century, B.C., is frequently cited as being a most complete compend of the opinions, practice, and prescriptions of the most eminent authors of this and preceding ages, the information embodied being further enhanced by succinct and definitely arranged psychological, physiological, and pathological annotations. Voluminous publications devoted to Therapy and Jurisprudence also characterized this period, and in certain departments of medical law, the Celestial physicians, as they do to-day, enjoyed an exalted reputation. "Among other instances of superiority in this respect," remarks Surgeon Gordon,† "to which, with or without reason, they pretend, is the method by which they affect to discover whether a man found dead by strangulation had been his own executioner, or been strangled by others; whether, in the case of a body being found in the water, death preceded, or followed, the immersion; and whether in other cases death had been the result of natural causes, or felonious violence."

According to generally conceived and accepted opinion, smallpox first made its appearance in the Orient somewhere about A.D. 317-420, but a comparatively recently discovered work entitled *Tao-u-tchin-fu*, a copy of which is in possession of the British Museum, speaks of it definitely and specifically, as known to the Chinese at least twelve cen-

turies prior to the Christian era; and presumably it is of much greater antiquity, but confused with other epidemics because of the term translated *plague* or *leprosy*, which was indiscriminately applied to all infectious and contagious maladies. Inoculation was a common practice in the earlier years of the *Chow* dynasty, somewhere about 1122 B.C. Yet the Celestials, then and now, placed less confidence therein than do Caucasians in vaccination at the present day; ‡ they assert that not only is the inoculation of variola virus oftentimes a failure so far as procuring immunity to subsequent attacks of the malady, but that the natural process of infection is equally untrustworthy,§—a fact that modern pathologists have been very reluctant to acknowledge.

Nearly four thousand years since, Chinese physicians definitely and correctly described Asiatic cholera, along with its pathological lesions; employing the same name as that which at present accrues to the malady in the Flowery Kingdom,—viz., *hwo-luan*. Also characteristic descriptions of intermittent and remittent fevers, the former accurately and minutely portrayed in works of at least six centuries' greater antiquity. Tuberculosis—*phthisis*—likewise was taught as an acute infectious disorder, the disease being conveyed by means of a minute "worm" found in the pulmonary exhalations of the patient. Evidently the *bacillus tuberculi* is not of modern origin. Crises in disease, and the natural tendency of the economy to relieve itself by

† Hamilton's "History of Medicine," vol. i. p. 30.

‡ Inoculation, as practised in the Orient,—the Indies, China, and the Levant,—was formerly doubtless well understood in all its pathological relations. It is now generally alluded to under the somewhat poetical expression of "cultivating Heaven's flowers," but manifestly invoked more as a *fetich* to conciliate the demon of the disorder, for other materials than variola virus are often added. The allusion, however, implies in former times the object was really "the development of a natural disease, the poison of which is latent in the system, exactly as fire is concealed in the flint" (Hamilton). If this be a true interpretation, the inference is that with the decadence of scientific knowledge the real object of the operation has been forgotten; there remains only an esotericism, and *prevention* has usurped the place of *cultivation*. Such particulars have a most important bearing upon the general system of "inoculation" for various diseases as now practised. They indicate, moreover, the importance of research in works referring to times past; and they point to similar results from the new system of "inoculation" as those which characterized the old. ("History of Medicine and Medical Opinion," by Surgeon-General Charles A. Gordon, M.D., C.B.)

* This emperor is supposed by some to have been the Esculapius of the Greeks.

† "History of Medicine and Medical Opinion."

spontaneous or critical evacuations at certain periods, were eulogized at the time of Ho-angti; and those suffering from febrile disorders were observed to exhibit marked change every seventh day.

"There are six sorts of distempers," wrote Chun-yu-y. "The first of the presumptive or haughty; the second of the covetous; the third of the poor; the fourth of those who have the *yin* and the *yang* inharmonious; the fifth those who from weakness are unable to accept remedies; the sixth those who credit impostors." And again, "Regard must be had to the age and constitution of the patient,—to his constitution, whether of plethora or inanition. It is necessary, likewise, to inquire into the various degrees of toxicity of poisonous remedies. . . . In short, we must not obstinately adhere to the letter of a rule on all occasions, but vary as circumstances may require."

Says Dr. Gordon, "Vital heat and radical moisture by the ancient Chinese medical writers constituted the two natural principles of life, of which the *blood* and the *spirits* are the vehicles. According to their physiology the body, with its *nerves, muscles, veins, and arteries*, resembled a stringed instrument, whose various parts have each its proper temperament or tone, suited to its particular conformation, situation, and uses. In the same manner as the string gives a different sound according to where it is touched, or the force employed, so, too, the *strings* of the body reveal whether they are too much *stretched* or *relaxed*. Herein we meet with the original ideas which at a date long subsequent were to assume a Western garb, and under such garb have their influence in medical science even down to our own day. For example, the idea of 'the spirits' and the blood being independent of each other, though united in life. . . . The theory of 'localization of function,' although discussed as a subject altogether new, is but shown in its proportions as compared with the corresponding theory expressed by the learned men of ancient China. Here, also, we find anticipated the doctrine of *strictum* and *laxum* to be long subsequently enunciated by 'classical' teachers, and brought down to the present day, for do we not still prescribe for 'nerves too highly strung,' and for 'systems relaxed' order 'bracing' air and tonics?"*

During the *Chow* dynasty, 1122 B.C., maladies were classified in accordance with their prevalence at particular seasons of the year :

headaches and neuralgias under *spring*; skin-affections under *summer*; fevers and agues under *autumn*; bronchial and pulmonary affections under *winter*,—a classification that in the main holds good in our own time. Great stress also was laid upon the value of the pulse as a factor in diagnosis, and in this modern Celestial physicians are remarkably clever, and they count twenty-four different styles of beats, besides various subdivisions. In the *Wang-Shua-ho*, issued about 500 B.C., occurs a special treatise entitled "The Doctrine of the Pulse," which refers to a still more ancient work devoted to the same subject, and it declares, "There are in the pulse a thousand differences, according to differences of age, sex, stature, and seasons."

In the sixth century B.C., *Chou-kwei*, a celebrated surgeon, flourished, and so skilful in his art, that he is said to have "cut open the abdomen, removed diseased viscera, and neatly sewed it up again without the patient having suffered anything." Here we have evidence of early employment of anæsthetics, which, both general and local, were known to India much earlier. An operation, surmised to have been an ovariectomy, is also referred to the second century B.C., and at the same time it is written: "If the sick man is suffering from some internal complaint, and medicines produce no satisfactory result . . . the surgeon now takes a sharp knife, and opens the abdomen, proceeding to wash the viscera with medicinal liquids, but without causing him the slightest pain.† The washing finished, he sews up the wound with *medicated* thread, puts over it a plaster, and at the end of twenty days or a month the place is healed up!"

We also read that *Hwa-to* in the third century B.C. enjoyed especial eminence on account of the wonderful cures effected by his skill, and that he met his death by decapitation for refusing to *trepan* a famous military despot. From this time medicine steadily declined in the Flowery Kingdom, and some-

† We are necessarily involved in doubt as to the character of the anæsthesia produced. Now and then the employment of *hascish* is alluded to; we know local anæsthesia has been a Chinese practice for centuries,—or it may have been hypnotism. In many instances hypnotism is specified, the manipulators and operators on several occasions being women. General Gordon notes that the juice of monk's-hood (aconite) is employed to procure local anæsthesia, also several species of fungi, and an exudation procured from frogs and other reptiles. Also that the doctrine of "blood-poisoning" meets with general favor, to the manifest advantage of nostrum venders and charlatans, who on every hand vaunt the virtues of "blood-purifiers."

where between B.C. 238 and 210, during the reign of Chi-Hoang-Ti of the vandal *Tsin* dynasty, the greater part of Chinese literature was destroyed, save works devoted to architecture and astronomy. Formerly with high claims for consideration, and notably superior to that of the Greeks, Chinese medicine has now so degenerated as to present a strange jumble of fetichism, astrology, and superstition, with here and there a few really valuable observations.

Lamaism possesses a voluminous literature, sacred, philosophical, scientific, theological, psychic, and historical, in all several hundreds of volumes classified as *Bkah-hgyur*, *Bstan-hgyur* (derived from India as supposed), and *Mani-Kambum* (of local origin). The first is made up of books of discipline, philosophy, metaphysics, doctrines, Buddhistical transmutations, incarnations, and the *Sutras*,—"collections of precious things," "liberations from pain," and "incantations." Between two and three hundred volumes are enumerated in the *Bstan-hgyur*, some few poetical and epical, some devoted to dogmas, but the greater part devoted to philology, medicine, therapeutics, physiology, psychology, and natural science. The *Mani-Kambum* contains the legends of the propagation of Buddhism, a description of the *Sukhavati*, or region of *perfected bliss*, ethics and religious ordinances, dissertations upon the mystical sentence *Kum om Padma* (Maya, *Con-exomon pan-ex*), including its "meaning, irresistible power," etc. As may be imagined, all are esoteric and mystical, and but little known outside of the sacred monasteries of Lhasa and Pekin. The three grades of priesthood also exhibit a mystical origin. The highest is *Chang-Chhub*, "the Perfected," or "True Intelligence." This may be reached only through the *Chang-Chhub-Sempali*, or "Perfected Strength of Mind,"—the analogue of the Sanskrit *Bodhisatwas* and Chinese *Pusas*. Lastly, the *Pratyeka*, or "Individual Intelligence," whose ranks are recruited from the acolytes or "Listeners,"—*Seavaka*.

In his translations of the cuneiform records of ancient Assyria, Mr. Sayce affords us some further insight into the status of Therapeutics in Nineveh and Babylon. He declares the medical profession to have been in a much more advanced state than the world has generally surmised. All the known diseases were classified, their symptoms described, the medical mixtures considered appropriate to each case being compounded and prescribed in quite the nineteenth century fashion. "Dis-

orders of bile" then, as now, had much to answer for. A prescription given in fever calls for "cypress extract, goat's milk, palm wine, barley, the flesh of the ox or bear, and the wine of the cellarer." In this we see a hot, stimulating, carminative draught not very dissimilar to what is often prescribed in like cases in our own day. Dr. Gordon remarks thereupon, "This method of treatment obtains significance if we refer to certain prescriptions in our own country (Great Britain) as recently as A.D. 1737,—namely, 'Make a decoction of the root of English or Flemish cypress bruised in white wine, and, after it is strained, drink the wine as hot as possible; 'tis an approved remedy for the colic.'"
Here is another, of a plant called *cypress Indicus*, but which is more properly *curcuma longa*,—namely, "the fruit is good to eat when it is boiled with meat (the modern *curry*). This *turmeric* is aperient, detersive, proper to relieve obstructions of the spleen," etc.* At the present time, instead of goat's milk and the flesh of the ox or bear, we substitute beef essence with stimulants, including the "wine of the cellarer."

In rules laid down for arriving at a correct diagnosis, the Assyrian physician was enjoined to "observe the sick man's countenance. If it shows a white appearance, his heart is cured; if it shows a dark appearance, his heart is still devoured by fever; if it shows a yellow appearance during the day, the patient's recovery is assured; if it shows a black appearance, he will grow worse, and will not live."†

APPENDIX.

O.

"Among the upper classes of citizens there was one . . . who . . . bore the Greek name Nicodemus, and was a ruler, a foremost man, in the religious world of Jerusalem, a member of its governing class, and in sentiment and party a Pharisee. . . . He was a man of advanced years and high position, and might, no doubt, have done good service to Christ's worldly interests among the influential classes, and have even helped toward a coalition of the priests and Pharisees with Him, had his aim been national and religio-political like theirs. There was, inevitably, a strong prejudice in Jerusalem against a movement which had begun in Galilee, and was supported by Galileans, and Nicodemus might have helped to counteract it. . . .

"As a *Rabbi*, Nicodemus was necessarily skilled in the subtle expositions of the Law for which his order was famous, and must have been familiar with the Scriptures throughout, but he had been trained to the *artificial* (i.e., esoteric) explanations of the Schools, and was *profoundly unconscious of their deeper meaning*.

* Pomet, p. 35.

† Vide Chas. A. Gordon.

Like others, he supposed that a Messiah would set up a theocracy distinguished by zealous fulfilment of the Law; every Israelite, as such, forming a member of it. Greeting Jesus as one whom he and others in his position acknowledge to be a 'Master' (one of the *Mystai*) . . . any question as to his own admission to the kingdom (Perfection) had not crossed his mind. . . . Israel as such would be saved (Perfected) . . . God had sanctified Israel to Himself forever, and made every Jew as such, on a footing. . . . Trusting implicitly in his being a Jew as a divine title to citizenship in the new theocracy, and thinking only of formal acts by which he might show his devotion and increase his claim to the favor of God, here and hereafter, he is met by an announcement that neither national descent nor the utmost exactness of Pharisaic observance, nor any good works however great, as such, availed at all to secure entrance into the kingdom. . . . Jesus broadly told him that his whole conceptions were fundamentally wrong. Every man, whatever his legal standing, must be *born again* if he would see the kingdom of God. To do so is not a question of acts, legal or moral, but of their motive. The idea of being born again should not have been incomprehensible to a Jewish *Rabbi*, for . . . '*creating a clean heart and renewing a right spirit*' are expressions that must have been familiar to him in the Law, and the Prophets, and the Psalms. But the full meaning of such terms had been lost in the prevailing externalisms (esotericisms). He took the words in their literal sense. In his perplexity he supposed that what was demanded was in some way connected with his nationality, which he assumed already opened an unquestioned entrance for him into the theocracy." (Geikie's "Life of Christ," chap. xxx.)

P.

Such an illustration shows how trivial an impression may be recorded and preserved; and if, on such an inorganic surface, an impression may thus be indelibly marked, how much more likely in the purposely constructed ganglion! A shadow never falls upon a wall without leaving thereupon a permanent trace,—a trace which might be rendered visible by resorting to proper processes.

Dr. Draper, commenting upon such fact, adds, "Photographic operations are cases in point. The portraits of our friends, or landscape views, may be hidden on the sensitive surface from the eye, but they are ready to make their appearance as soon as the proper developers are resorted to. A spectre is concealed on a silver or glassy surface until, by our necromancy, we make it come forth into the visible world. Upon the walls of our most private apartments, where we think the eye of intrusion is altogether shut out and our retirement never profaned, there exist the vestiges of all our acts, silhouettes of whatever we have done.

"If, after the eyelids have been closed for some time, as when we first awake in the morning, we suddenly and steadfastly gaze at a brightly-illuminated object and then quickly close the lids again, a phantom image is perceived in the indefinite darkness beyond us. We may satisfy ourselves that this is not a fiction, but a reality, for many details we had not time to identify in the momentary glance may be contemplated at our leisure in the phantom. We may thus make out the pattern of such an object as a lace curtain hanging in the window, or the branches of a tree beyond. By degrees the image becomes less and less distinct: in a minute or two it has

disappeared. It seems to have a tendency to float away in vacancy before us. If we attempt to follow it by moving the eyeball, it suddenly vanishes. Such a duration of the retina proves that the effect of external influences on nerve-vesicles is not necessarily transitory. In this there is a correspondence to the duration, the emergence, the extinction of impression on photographic preparations. Thus I have seen landscapes and architectural views taken in Mexico developed, as artists say, months subsequently in New York, the images coming out after the long voyage, in all their proper forms and in all their proper contrast of light and shade. The photograph had forgotten nothing: it had equally preserved the contour of the everlasting mountain and the passing smoke of the bandit fire.

"Are there then contained in the brain more permanently, as in the retina more transiently, the vestiges of impressions that have been gathered by the sensory organs? Is this the explanation of memory,—the Mind contemplating such pictures of past things and events as have been committed to her custody? In her silent galleries are there hung micrographs of the living and the dead, of scenes that we have visited, of incidents of which we have borne a part? Are these abiding impressions signal-marks, like the letters of a book, which impart ideas to the mind; or are they actual picture-images, inconceivably smaller than those made for us by artists in which, by the aid of a microscope, we can see in a space not bigger than a pin-hole a whole family group at a glance?

"The phantom images of the retina are not perceptible in the light of the day. Those that exist in the sensorium in like manner do not attract our attention so long as the sensory organs are in vigorous operation, and occupied in bringing new impressions in. But when these organs become weary or dull, or when we experience hours of great anxiety, or are in twilight reveries, or are asleep, the latent apparitions have their vividness increased by the contrast, and obtrude themselves upon the mind. For the same reason they occupy us in the delirium of fevers, and doubtless also in the solemn moments of death. During a third part of our life, in sleep, we are withdrawn from external influences: hearing and sight and the other senses are inactive, but the never-sleeping Mind, that pensive, that veiled enchantress, in her mysterious retirement, looks over the ambrotypes she has collected,—ambrotypes, for they are truly unfading impressions,—and, combining them together, as they chance to occur, constructs from them the panorama of a dream. Nature has thus implanted in the organization of every man means which impressively suggest to him the immortality of the soul and a future life. Even the benighted savage thus sees in his visions the fading form of landscapes, which are, perhaps, connected with some of his most pleasant recollections; and what other conclusion can we possibly extract from those unreal pictures than that they are the foreshadowings of another land beyond that in which his lot is cast? At intervals he is visited in his dreams by the resemblances of those whom he has loved or hated while they were alive; and these manifestations are to him incontrovertible proofs of the existence and immortality of the soul. In our most refined social conditions we are never able to shake off the impressions of these occurrences, and are perpetually drawing from them the same conclusions our uncivilized ancestors did. Our more elevated condition of life in no respect relieves us from the inevitable operation of our own organiza-

tion, any more than it relieves us from infirmities and disease. In these respects, all over the globe, men are on an equality! Savage or civilized, we carry within us a mechanism which presents us with mementos of the most solemn facts with which we can be concerned. It wants only a moment of repose or sickness, when the influence of external things is diminished, to come into full play, and these are precisely the moments when we are best prepared for the truths it is going to suggest. That mechanism is no respecter of persons. It neither permits the haughtiest to be free from the monitions, nor leaves the humblest without the consolation of the knowledge of another life. Open to no opportunities of being tampered with by the designing or interested, requiring no extraneous human agency for its effect, but always present with every man wherever he may go, it marvellously extracts from vestiges of the impressions of the past, overwhelming proofs of the realities of the future, and, gathering its power from what would seem to be the most unlikely source, it insensibly leads us, no matter who or where we may be, to a profound belief in the immortal and imperishable, from phantoms which have scarcely made their appearance before they are ready to vanish away." (Abstract of views presented by Dr. Draper in his work on "Human Physiology," and in the chapters devoted to "Inverse Vision or Cerebral Sight.")

"The only path to scientific human psychology," the author further remarks, "is through comparative psychology." It is a long and wearisome path, but it leads to Truth. Is there, then, a vast spiritual existence pervading the universe, even as there is a vast existence of matter pervading it,—a spirit which, as Kant tells us, sleeps in the stone, dreams in the animal, awakens in man? Does the soul arise from the one as the body arises from the other? Do they in like manner return, each to the source from which it has come? If so, we can interpret human existence, and our ideas may still be in unison with scientific truth, and in accord with our conception of the stability of the unchangeability of the Universe. (See "Conflict of Science." p. 138.)

Q.

EVIL SPIRITS.—In connection with the doctrine of Evil Spirits, let me call attention to an article appearing in the *Galaxy* of January, 1885. Here is given the character of Mr. Home, widely known as the "Great Apostle of Modern Spiritism," but he confesses himself a firm believer in Christianity.

"Mr. Home declares that belief in spiritualism is by no means a religious belief, and has nothing to do with man's religious faith. . . . He says they (the spirits) are not allowed to teach us . . . because we would depend too much on them. . . . An old gentleman . . . asked, 'Mr. Home, do you believe that Jesus Christ died for sinners, and that by faith in him alone we are to be saved?' 'I do, sir!' he answered. . . . 'Well, I've heard a great many spiritualists talk, but I never yet saw one that acknowledged . . . the Saviour.' . . . 'Then look at me,' emphatically answered Mr. Home. He does not pretend to explain this power of mediumship; it is like the gift of a fine voice or a talent for painting. . . . The science of spiritual manifestation is subject to certain natural laws as yet not understood. Much depends upon the atmosphere. . . . Mr. Home charges those who would investigate the subject to exercise the greatest care in the choice of a medium. He says every human being attracts to him or herself

. . . sympathetic companions; that we are invisibly surrounded by those who are like ourselves, and mediums therefore are under the influence of those who are drawn to them by likeness of character. In this way he accounts for the much injury done spiritualism through the communications of lying spirits, and the immoral social influence of many mediums."

It is needless to remark, perhaps, that Mr. Home is wholly unfamiliar with the doctrines of the Mysteries.

EXPERIMENTAL SCIENCE.—For more complete information regarding the researches of Messrs. Crookes, Wallace, Hallet, and others, I refer my readers to the Transactions of the (English) *Society for Psychical Research*.

MYSTICAL ORIGIN OF JUDAISM.—In the xxiv. chapter of Exodus, the 9th, 10th, and 11th verses compose a paragraph which reads as follows:

"Then went up Moses, and Aaron, Nadab, and Abihu, and seventy of the elders of Israel: and they saw the God of Israel: and there was under his feet as it were a paved work of sapphire stone, and as it were the body of heaven in clearness. And upon the nobles of the children of Israel he laid not his hand: also they served God, and did eat and drink."

See also Isaiah vi. 1-5; 1 Timothy vi. 16; Exodus xxiv. 17; Ezekiel i. 26-28; do. x. 1-22; Revelation iv. 2-6; Deuteronomy iv. 33; and compare these with the extracts from the Book of Enoch (THERAPEUTIC GAZETTE, August, 1887, p. 541. Appendix N), the Popal-Vuh, Books of Daniel, etc.; and likewise with the statement of Proclus, the philosopher and disciple of Plato: "In all initiations and mysteries the gods exhibit themselves under many forms, and appear in a variety of shapes. Sometimes their unfigured light is held forth to view; sometimes this light appears under a human form, and sometimes it assumes a different shape."

We are told regarding the Mysteries of Eleusis that to those who *failed* in the ordeals by which was reached the second degree, that of *Ephori*, were administered powerful narcotic drugs that "plunged them into a death-like sleep, from which they emerged with confused recollections, if not in entire forgetfulness of the terrible scenes they had witnessed, and which they believed to be produced by some frightful dream or dreadful nightmare." Again, that all the human mind can imagine that would excite the passions, were placed within the grasp of the candidate for *Epopsteia* (the highest degree). Nothing that could possibly entice from a state of moral and physical purity was omitted. But if in a moment of weakness they allowed their senses to obtain the mastery over reason, their bright surroundings suddenly disappeared, and they were plunged into the most dense obscurity; they were precipitated into a deep abyss, from which if they escaped with life it was at the expense of reason.

PORT HURON, MICHIGAN.

ANTIPYRETIC PILLS.

BY B. FRANK HUMPHREYS, M.D., HAWKINS, TEXAS.

THE occasional untoward effects of antifebrin, antipyryn, and the whole catalogue of "anti-quinine" rivals, and the alleged pathological changes which have been ob-

served to follow their administration, have made many practitioners more cautious in the use of these new remedies, and more inclined to fall back upon the old and less dangerous methods. The following formulæ have been devised and used with satisfactory results by the writer before the more recent antipyretics came into general use. If some of the manufacturing pharmacists will include them in their formula lists, they will doubtless find ready sale for them, as few physicians or druggists are in a position to prepare them properly. Distant patrons, who are familiar with their use, send to me for my "fever pills," and manage most of their malarial sickness with success. No. 1 is especially adapted to general family use, meeting the indications in ordinary cases of malarial fever.

The other numbers, as a general rule, should be preceded by, or alternated with, calomel. The two- or three-grain sugar-coated pill, to the amount of six or ten grains, followed by a saline laxative, is the most efficient hepatic remedy.

These antipyretic pills, as the term indicates, are designed to reduce the fever, and may be given in any stage of the pyrexia. They act not only as an antipyretic, but at the same time prove to be our most reliable antiperiodic. The fever usually subsides, if of the periodic type, by the time the patient becomes thoroughly cinchonized, diaphoresis being established after a few doses, followed by a gradual decline of the temperature.

NO. 1.

R Quinine, gr. ii;
Calomel, gr. i;
Antim. et pot. tart., gr. $\frac{1}{2}$;
Morphine sulph., gr. $\frac{1}{4}$. M.

Fiat P. 1.

Sig.—One or two pills every two hours until the fever subsides, or until ten pills have been administered. Usually one pill every two hours is sufficient. In urgent cases one or two pills every hour may be required.

NO. 2.

R Quinine, gr. ii;
Ipecac, pv., gr. $\frac{1}{4}$;
Camphor, pv., gr. $\frac{1}{4}$;
Gelsemine, gr. $\frac{1}{4}$. M.

Fiat P. 1.

Dose same as the preceding formula.

NO. 3.

R Quinine, gr. ii;
Ipecac, pv., gr. $\frac{1}{4}$;
Camphor, pv., gr. $\frac{1}{4}$;
Pilocarpine, gr. $\frac{1}{4}$. M.

Fiat P. 1.

Dose same as first formula.

NO. 4.

R Quinine, gr. ii;
Opium, pv., gr. $\frac{1}{4}$;
Ipecac, pv., gr. $\frac{1}{4}$;
Ext. aconite, gr. $\frac{1}{4}$. M.
Ft. P. 1.

Dose same as first formula. The drugs should be strictly pure and accurately divided.

These pills are not designed to take the place of a physician's prescription, nor are they intended to be used throughout an attack of fever when other and special treatment is obtainable. They may be conveniently used at the onset of a malarial fever, or at any time during its progress, to establish diaphoresis and hasten the apyrexia, after which the treatment indicated may be prescribed.

ANDROMEDOTOXIN.

DE ZAAVER has prepared considerable quantities of andromedotoxin from *Rhododendron ponticum*, and gives its properties as follows (*Chem. Zeit.*): It is in white, delicate, crystalline needles, melts at 228° or 229° C., soluble in alcohol, amyl alcohol, chloroform, ether, and benzol, and less soluble in hot than in cold water. The solutions in water, alcohol, and amyl alcohol are lævogyre, while a solution in chloroform is dextrogyre. It yields alkaline solutions, is not precipitated by the alkaloidal reagents, nor by solutions of metallic salts; it does not reduce Fehling's solution. When heated with dilute sulphuric, hydrochloric, or phosphoric acid it assumes a beautiful rose color, the shade varying somewhat with the acid used. $C_{27}H_{51}O_{10}$ is the formula assigned to it.—*Druggists Circular and Chemical Gazette*, October, 1887.

CRYPTOCARYA AUSTRALIS.

The physiological action of *Cryptocarya australis* has lately been investigated by Dr. Bancroft, of Brisbane. This small tree belongs to the natural order of Laurineæ, and is plentiful about Brisbane. The bark has a persistently bitter taste, due to the presence of an alkaloid which crystallizes from its solution in stellate masses of acicular crystals. When administered to warm-blooded animals the alkaloid produced difficulty of respiration, ending in asphyxial difficulty and death. It also had a poisonous action on cold-blooded animals belonging to the reptilia.—*Pharmaceutical Journal and Transactions*, October 1, 1887.

MALARIAL ORGANISMS.

AT a meeting of the Pathological Society of Philadelphia, held October 27, Dr. Councilman, of the Johns Hopkins University, read a very interesting account of researches made during the present season upon malarial blood. He found in greater or less abundance the whole series of organisms which have been described by various observers as existing in the blood of malarial patients. The segmental organism which Professor Osler, of this city, first stated to be peculiar to the period just before or during the chill he found in a large number of cases always at this period, and believes it to be a characteristic of the stage. The crescentic organism he found solely in malarial cachexia, in which affection, when intense, it often exists in extraordinary abundance. Dr. Councilman found no difficulty in obtaining blood directly from the spleen with a hypodermic syringe. He always took the precaution to throw the whole syringe into boiling water before using it, and never saw any evil results follow the plunging of the sterilized syringe-needle deep into the splenic tissue. The blood of the

spleen was found to be especially the home of the various organisms, and it was chiefly from it that the flagellated form of the organism was obtained.

The effect of the administration of quinine upon these organisms was carefully studied. The influence of large doses of the alkaloid upon the most characteristic organism—namely, that which accompanies the acute intermittent and is characteristic of the chill period—was most pronounced. Fifteen grains of quinine given daily for three or four days would often be followed by the almost complete disappearance of the organism, and whilst the administration of 45 grains daily for three days always caused the organism to disappear completely. On the other hand, the crescentic organism of the malarial cachexia did not appear to be particularly affected by quinine. Thus in one case 45 grains a day of the alkaloid were given for six successive days, and then 60 grains a day for three successive days, but at the end the crescents were about as numerous in the blood as they had been before any drug was given. Dr. Councilman has made a limited number of transfusions of malarial blood into the blood of a rabbit, and has repeatedly found the organisms in the blood of one ear a few moments after malarial blood had been injected into the other ear. In a number of cases the crescentic organism was found to be embedded in one of the white blood-corpuscles, and apparently white blood-corpuscles in a manner seize the foreign organism and destroy it.

During the discussion of this paper Dr. Osler made a statement that a Canadian medical friend insists that the wild geese coming southward to the malarial flats of Southern Canada frequently suffer from malarial fever, and that he himself examining the blood of one of these geese had found one or two organisms which he could not distinguish from those of the malarial human blood.

Dr. Councilman's researches undoubtedly strengthen the theory that the organisms in the blood are the cause of malarial fever, although it cannot be considered that this theory is proven. As therapeutists we are especially interested in the effect of quinine upon these organisms. The relations between the chill organisms and the crescents are extremely obscure, no observer having as yet traced any intermediate state. Arsenic was found by Dr. Councilman to be without apparent influence upon the crescents. Now, if the crescents are the cause of malarial cachexia, why is it that

they are not influenced by quinine and arsenic, although these agents will cure chronic as well as acute malaria? No satisfactory answer was given by Dr. Councilman, or, indeed, can at present be given to this inquiry.

MAMMARY ELIMINATION.

THE question of elimination of drugs from the mammary glands of the female is one of practical interest. Our own experience leads us to believe that only in very rare instances do medicinal substances find their way into the mother's milk in sufficient quantities to affect the offspring. This conclusion is measurably confirmed in a paper recently published in the *American Practitioner*. Dr. John G. Cecil there concludes that it is practically impossible to medicate the child through the nurse's milk; on the other hand, he advances evidence to show that certain narcotics, and even other substances, may sometimes find their way into the lacteal fluid in sufficient quantities to produce acute poisoning in the child. Every one knows that the oil of garlic will in the spring appear in cow's milk in sufficient quantity to be disagreeably recognized. Among the cases cited by Dr. Cecil several seem to us worthy of especial note.

Opium.—In the *American Journal of Obstetrics*, June, 1885, is reported by Dr. O. W. Doe a case of galactorrhœa in which, the patient being restless and nervous, 20 drops of tr. aceti opii, with 30 grains of potas. brom., were given at 10 A.M., but no sleep followed. The baby, on the contrary, could not be roused during the whole day sufficiently to nurse; the pupils were markedly contracted, and the narcotism was so pronounced as to give rise to much anxiety. According to Dr. Cecil, an infant two days old, in Manchester, England, died soon after taking the mother's breast for the first time. The symptoms were said to have been those of opium-poisoning. The mother was a habitual opium-eater, using weekly about an ounce of the drug. A similar case was reported in *Annales de Gynecologie* for August, 1876. Those of our readers who have noted in our review of Dr. Erlenmeyer's book the statement that infants born of opium-eaters are very liable to sudden collapse after birth for want of opium, will agree with us in thinking it possible that in the two cases just cited the children died from lack of opium rather than from opium-poisoning. Dr. Fehling found that hypo-

dermic injections of morphine given to the mother do not affect the child. The explanation of opium-collapse cannot, however, apply to a case reported by Dr. Cecil himself, in which the child was six weeks old.

Atropine.—Dr. Schling reports in the *Journal de Médecine*, February 20, 1887, some experiments with the alkaloid of belladonna. Hypodermic injections of $\frac{1}{15}$ to $\frac{1}{20}$ of a grain of atropine produced a decided impression on the mother. Dilatation of the child's pupils followed, which disappeared in twenty-four hours. Dr. Ouchterlony gave to Dr. Cecil the record of a case in which, after the administration of hyoscyamus to the mother, the child's pupils became widely dilated and its face flushed, and other symptoms of poisoning appeared, which subsided upon the withdrawal of the remedy.

Salicylate of Sodium has been found by Fehling and Schling in the child's urine about one hour after its administration to the mother. *Mercury* was at one time frequently administered to the mother for the purpose of affecting the child, but the practice has gone into desuetude. Conjoined clinical and experimental evidence seems to show that although the mercury does pass from the mammary glands occasionally, its elimination is too feeble and too uncertain to be relied upon. There is reason for believing that the *iodides* are more frequently eliminated with the milk, and Dr. Cecil records a case of marked iodism in the babe following the exhibition of the drug to the mother.

Arsenic and *antimony* appear to pass with some readiness through the mammary glands. (See *Journal of the American Medical Association*, September 12, 1885.) M. Gabriel Bouchet, to determine whether *arsenic* is eliminated by the milk, gave Fowler's solution in large doses to a number of wet-nurses, and found a notable quantity of the metal in the milk. Lewald states that he has found arsenic in the milk seventeen hours after its ingestion, and that even forty hours later the metal could be detected.

QUARANTINE AGAINST CHOLERA.

AT a discussion in the College of Physicians, held on October 27, the special committee that had been appointed to examine the condition of the quarantine at New York, Philadelphia, and Baltimore made a long and very able report upon the subject. This report revealed a condition of affairs

most extraordinary, and which, unless remedied, must before long lead to an outbreak of cholera that will probably spread throughout the whole United States. When it is remembered that there are in this country fifty millions of people, who are continually travelling to and fro, that many of our cities are filthy, and that cholera is a disease that spreads with extreme and uncontrollable rapidity, the importance of the subject becomes apparent. A personal careful investigation by the committee showed that in neither of the cities was there proper provision for the prevention of the ingress of the disease. The details of this report will, without doubt, be printed in most newspapers of the United States before the THERAPEUTIC GAZETTE can get to press, and we do not therefore occupy space with them, but content ourselves with calling attention to certain potent facts.

In the first place, the treatment of the passengers of the affected ships in New York harbor seems to have been simply abominable. Hundreds of men and women, some infected, others not, were for several days crowded in a single large room. They had, at least at first, no bedding at all, and when bedding was received it was simply thrown upon the floor, and during the day piled up in heaps, no care being exercised to see that the same individual had the same blankets on successive nights. There were no proper latrines, no proper protection of the water-supply from infection, and the system of disinfection was so bad that for several days the unfortunate people had no access to any clothes save those on their back. There was no isolation of the groups of passengers, and no attempt at separation of the possibly infected from the well. There was no medical attendance upon the island during the night. Any person taken with cholera at such time had to remain without assistance among the well persons until the visit of the health-officer the next day. Even in the hospital upon an adjacent island, with its ill and dying patients, there was no resident physician, and therefore no proper surveillance of the patients, who apparently were visited only once in twenty-four hours.

In the second place, the police supervision was so faulty as practically scarcely to exist, and there can be no doubt that boats passed freely between the infected island and the shore. If under such circumstances cholera has died out, an old-fashioned coroner's jury sitting upon it would be well justified in

bringing in the old-time verdict, "Died by the grace of God."

In the discussion at the College of Physicians which followed the reading of the report of the committee, Dr. J. C. Peters, of New York, made some statements as to the cause of the inefficiency of the New York quarantine. He said that it was due to lack of money, although the receipts of the office are estimated at from sixty to one hundred thousand dollars a year. Of this money ten thousand goes to the medical health-officer, seventeen thousand to the expense of the office, and the remainder, according to Dr. Peters, fades away,—it being generally understood that the quarantine office is the main reliance of one of the political parties in the State of New York for campaign expenses. The question naturally arises, Is it quite proper that the whole United States of America should be exposed to a decimation of its people in order that a political party in New York State may maintain a struggle for supremacy? Perhaps the sacrifice may be worth making for the end, but we have ventured to doubt it.

Probably after the country has been ravaged by cholera the wise men at Washington who rule so unwisely will rise above local jealousies and local feelings and devise a general quarantine law to be enforced by the United States authorities,—a law which if put in operation now might save thousands of lives. New York commerce is of course of importance to New York, but New York is simply one of the gate-ways to the United States, and surely the people of the United States have as much interest in the question of the entrance of contagious disease as have the people of New York themselves. If the United States government have a right to interfere with the commerce of New York, as it does by taxation, it must also have the right to further interfere as far as may be necessary for the protection of the people. Quarantine is not a local, but a general question. The gate-ways to the country are many, and the series of quarantine stations make a chain whose strength is measured by that of its weakest link. A little port upon the Atlantic, powerless from poverty to enforce proper quarantine regulations and to make proper provisions for those who are detained, may become the starting-point for a wave that shall sweep like a besom of destruction over the whole country. Moreover, at present a city is not responsible for its own quarantine and is not able to protect itself. The State of New York, not the city of New

York, dominates the quarantine station at New York, and if such a great Commonwealth, vastly superior in its intelligence and in its wealth to almost any other State of the Union, prefers to steal from its own quarantine stations money for political purposes, what can be expected of a small State like that of North Carolina, with its port of Wilmington, perchance poor, struggling with debt, and really unable to properly protect itself from disease-invasion?

CALOMEL AS A DIURETIC.

THAT various mercurial preparations are capable of acting as powerful diuretics is well known from the observations of Jendrassik, Stiller, Leyden, Fürbringer, Rosenheim, Senator, and others. It seems to be clearly established that calomel under certain circumstances is a most active diuretic, while under other conditions, as the readers of the *GAZETTE* will remember from articles already published on this subject, failure attends its employment under these indications. The conditions under which the greatest divergence of opinion obtains as to the value of calomel as a diuretic is in the case of hepatic diseases, in which condition authorities may be referred to who claim on the one side positive and on the other entirely negative action. This state of affairs is somewhat simplified by a paper published by Dr. W. P. Meyjes in the *Deutsche Medicinische Wochenschrift* for September 1, 1887. Dr. Meyjes tested the diuretic effects of calomel in fifteen cases in the clinic of Professor Pel. In eight of these cases a positive result was obtained; in the other, the diuretic action was slight or completely negative. His cases fall under the following groups: 1. Degeneration of the heart-muscle; 2. Organic heart-failure, with insufficient compensation; 3. Diseases of the liver; 4. Dropsy from other causes than those referred to. In the first two of these groups Dr. Meyjes's result confirmed other observers, the result being, as a rule, favorable, although he did not succeed in obtaining as striking effects as have been claimed by others. In the group of diseases of the liver his results are strikingly successful, with the exception of a single case of cirrhosis of the liver, where calomel was employed for three days with no evident results. On the other hand, two cases of gall-stone treated by this method are re-

ported, in which a marked diuretic effect was produced, and a reduction of the jaundice and suppression of the attacks of colic. In the fourth group, which includes cases of anæmia resulting from various cachectic conditions, kidney-affections, malarial or spinal disease, in no instance was the use of calomel followed by any improvement. Dr. Meyjes likewise discusses the cause of this production of diuresis by calomel, but with no further success than in attributing to calomel a specific diuretic action.

HYPODERMIC INJECTIONS OF CARBOLIC ACID IN CASES OF RHEUMATISM.

ACCORDING to the Vienna correspondent of the *British Medical Journal*, October 8, 1887, Professor Benedict has been using with extraordinary success hypodermic injections of two per cent. solution of carbolic acid in the treatment of rheumatoid affections. He asserts that in even a few months after the injection into the part the joint will be freely movable and free from pain as though narcotized, and in recent cases joints in which there was great tenderness on pressure and distinct swelling of the bones would be apparently free from disease a few days after the injections; not only would the pain disappear in the joints in whose neighborhood the injections had been practised, but would be markedly lessened in distant joints. Professor Benedict believes that the carbolic acid has not only a local influence, but a general effect in causing the elimination of the rheumatic poison. He has especially obtained good results by the simultaneous use of salicylic and carbolic acids when the salicylate of sodium is administered by the mouth in small doses, and one to three subcutaneous injections of carbolic acid being given in twenty-four hours, the course of the affection was very much accelerated, and no bad consequences were observed, especially if the treatment was carried out from the very beginning of the disease. Extraordinarily good results were obtained by the method in cases of inflammation of the sheaths of tendons, especially after injury. A few injections sufficed to cut short the morbid process, and no local pain or muscular atrophy, etc., was observed, provided the disease was treated in the above-mentioned way from the very outset.

ACETPHENETIDIN, A NEW ANTIPYRETIC.

KOBLER, of the medical clinic of Professor Bamberger in Vienna, describes his observations with this, the latest antipyretic, in the *Centralblatt für die Gesamte Therapie* for August, 1887. The formula for the composition of this substance may be written $C_6H_4NH.O.C_6H_5(CO-CH_3)$, its composition being analogous to that of antifebrin. It is a faintly reddish, odorless, and tasteless powder, very sparingly soluble in water, more soluble in glycerin, most soluble in alcohol, especially when hot. It is insoluble in acids or alkalies, and experiments have shown its insolubility in gastric juice and extract of the pancreas. After the use of the drug with healthy persons, in doses of from 8 to 10 grains, no effect was observed. In healthy persons body temperature was not influenced, while in fever patients, even after doses of 5 or 6 grains, a fall in temperature always occurred. In the writer's first use of the drug, as it was unknown, only small doses were employed,—from 3 to 6 grains; and after such doses a slight fall of temperature, persisting for a short time only, was observed. Doses of 8 grains were given afterwards, and finally it was the custom in the clinic to order 9 or 10 grains, as the doses previously given produced too feeble an effect. No especial idiosyncrasy against the drug was observed. The vomiting and depression so often observed after other antipyretics was never seen. As it is tasteless it was given in wafers, only to convey it better into the intestine. The drug was used in forty-eight cases,—eleven of pulmonary tuberculosis, ten of croupous pneumonia, seven of typhus abdominalis, six of measles, four of puerperal sepsis, three of pleurisy, two of pyæmia, one of a typhoid relapse, one of cerebro-spinal meningitis, one of acute purulent peritonitis, one of parametritis, and one of angina. The patients were generally between twenty and forty years old, one case a child of 9 years, ill with measles, on whom the dose of 3 or 5 grains produced a marked fall of temperature. In this case, as is usual in measles, continual high fever and well-marked bronchitis were present, in addition to the subjective symptoms. In no morbid process could a specific effect upon the disease be observed, but it was equally true that the effect of the drug was not to prolong any disease, as has been observed in the case of some other antipyretics.

Of ten cases of pneumonia treated with acetphenetidin six ended by crisis, and gen-

erally on the fifth or sixth day; among these was a case of Bright's disease. The drug was well borne in these cases, as it was also in another case, where, in addition to double pneumonia, acute nephritis was present. The patient was a person aged 20, who, while nursing three children ill with severe diphtheria, contracted a pneumonitis. The case bore the marks of an acute septic infection. As an antipyretic acetphenetidin was given in doses of 10 grains to 24 grains in twenty-four hours, without producing any symptoms of intoxication. The drug was apparently not irritating to the diseased kidney, as the quantity of blood in the urine became steadily less while the drug was taken, while the quantity of albumen contained was not influenced. The patient made a good recovery. The writer used the drug in question in accordance with the usage of Professor Bamberger, viz., to give antipyretics only when the temperature rises so high as to be dangerous to the organism and to its life. This drug, therefore, was given to patients whose temperature was 103.1° F., or 104° F., or 105° F. In these cases a fall of temperature of three or five degrees followed the administration of the drug. This fall of temperature occurred promptly after the taking of the drug. By allowing the thermometer to remain in the axilla it was observed that during the first quarter of an hour the temperature rose, but at the end of half an hour the temperature began to fall, and continued to fall from one-quarter of an hour to another one-tenth or two-tenths of a degree, so that after from four to six hours the maximum fall had occurred, for example, from 104.8° F. to 102° F. When the reduction had become established the temperature gradually rose in two or three hours one-tenth of a degree, and in the same ratio higher, until after eight or ten hours no effect of the drug upon the fever was apparent. The fall of temperature is generally more abrupt than the rise. The drug resembles all other antipyretics in the fact that its effect is most pronounced when given late in the afternoon or in the evening; it thus combines the natural depression of temperature with that generally produced by drugs. If the drug be given in the morning or early in the forenoon, a second dose will often be required to combat the usual tendency to rise of temperature at this time. In the case of a phthisical patient, the usual evening rise of temperature was completely prevented. The course of these cases was generally this: that by the administration of

the drug at ten or twelve in the forenoon, between four and six at evening the temperature became normal; at eight, ten, or twelve at night the temperature rapidly rose again, so that all traces of the original exacerbation had gone. This rapid rise of temperature was not, however, attended by chills or uncomfortable sensations, either in phthisical patients or the acute diseases.

As a rule, the rise in temperature was not attended by perspiration. Only in the cases of four phthisical patients, and one of a relapse in typhoid fever, did profuse perspiration follow the administration. These are the patients who are disposed to perspire freely, and with whom caution should be exercised in administering the drug. In one of these patients the experiment was made of attempting to prevent rise of temperature by the administration of doses of 5 grains of the drug every two hours. The second dose was given before the first had fully established its effect. In four hours' time, in addition to profuse perspiration, a sensation of chilliness and a rectal temperature of 95° F. resulted. It is worthy of note that, with other patients, this same mode of administration was employed without bad effects, and was apparently less energetic than the method of administration in larger doses. Among fever patients cyanosis and collapse never followed the use of the drug. It was especially noteworthy that in ten cases of pneumonia—a disease in which cardiac weakness is so often present—this phenomenon never appeared while this drug was used. On the contrary, the frequency of the heart's action was diminished, the filling and tension of the pulse were increased, phenomena which were not entirely due to the reduction of temperature, and which show that acetphenetidin is at least in no way injurious to the central organ of the circulation. By the great majority of patients a sensation of general well-being was a speedy result of the drug's action. The patients feel much lighter and more energetic, propose voluntarily to move about, and also to take food. If we are to accept this effect as a criterion for the use of an antipyretic, the drug under consideration is certainly of value in therapeutics. A diuretic effect was not observed. The urine was dark yellow in color; with ferric chloride a Burgundy-red color was produced, as is the case with many aromatic substances. The indophenol reaction was evident on using 9 grains of the drug. The urine of a patient taking this substance generally reduced an alkaline copper solution

very decidedly, but the reaction was not always present. Fischer's phenylhydrazin test was always negative, and sugar was not present. An increased passage of albumen, while taking the drug, was never observed. An increase in sulphates, as was found in experiments upon animals, could not be recognized after the use of small amounts of the drug.

The writer concludes that (1) acetphenetidin is an efficient antipyretic; (2) it produces no ill or unpleasant after-effects; (3) the dosage is by quantities of 1½ grains; (4) the administration of a considerable dose (8, 9, or 10 grains) is more useful than the repetition of small doses hourly or every two hours.

FRACTURE OF THE SPINE.

THE hopelessness of cases of fracture of the spinal column under the old expectant or do-nothing line of treatment is so complete that we do not hesitate to express our conviction that the surgeon should always endeavor to replace, if possible, the broken portions of the bone, and when the deformity is reduced, maintain a proper position by means of the plaster jacket or other similar mechanical contrivance. In a late number of the *Boston Medical and Surgical Journal* Dr. H. C. Burrell records five cases treated in this way in the Boston City Hospital with two recoveries. Usually the patient should be anesthetized and an attempt made to reduce the fracture whilst the body is in a prone condition. If this fail, suspension according to the method of Sayre should be essayed, although the procedure involves some danger of rupturing the spinal cord and, if the fracture is high up, of causing immediate death. The surgeon is, to our thinking, justified in taking this risk.

THE ANTIVIVISECTION AGITATION.

THE Philadelphia Society for the Restriction of Vivisection has recently indicated the true object of its existence, namely, the suppression of vivisection, by the publication for popular circulation of "Illustrations of Vivisection, or Experiments on Living Animals;" from the works of physiologists as reproduced in 'Barnard's Martyrs' and 'Light in Dark Places,' by Miss Frances Power Cobbe." In this pamphlet it is affirmed that society is in the face of a new vice, namely, the vice of scientific cruelty, and

that vivisection ought to be stopped. Miss Cobbe says, "The vivisector ought to be stopped in pursuing his (otherwise) lawful end of advancing physiological science, by his consideration that the means of advancing it involve a moral offence (theologically viewed, the sin), of causing torture worse than death to guiltless creatures. This consideration, as has been said, ought to stop him, just as any other man ought to be stopped in pursuing any legitimate end (*e.g.*, the advancement of the interests of his country or family) if he find he cannot carry it out without employing immoral means,—deceit, robbery, persecution, treachery, or any other unrighteous mode of action."

As this pamphlet has no immediate interest for our readers, being intended for popular circulation, we would not have occupied space with it had it not been for the persistent attempt of members of the medical profession to produce the impression that they are co-acting with the Philadelphia Society only in the endeavor to confine physiological experimentation to competent persons, and have no sympathy with the attempt to suppress the practice.

TREATMENT OF GONORRHOEA.

IN an elaborate article in the *New York Medical Journal*, October 8, 1887, Dr. O. T. Osborne discusses the question as to the specificity of gonorrhœa, and comes to the conclusion that it is proved beyond controversy that the gonococcus of Neisser is a special microbe which produces the disease, and that therefore the disease is specific. Notwithstanding this theoretical conclusion, Dr. Osborne asserts, as the result of his own experience, and as the general conclusion of most writers, that the abortive treatment of gonorrhœa with corrosive sublimate injections is unjustifiable and unsatisfactory, and that even weak antiseptic injections are to be combined with constitutional treatment. Our own experience is in accord with that of Dr. Currier, in believing that the use of large quantities of bismuth is the best treatment for the early stage of the disorder. Dr. Currier, as quoted by Dr. Osborne, employs an injection of bismuth and glycerin, 1 drachm to the ounce. We have always used the bismuth simply suspended by mucilage in water, giving the patients direction to shake the

bottle well before using, and to let it habitually stand on the cork so as to prevent the bismuth from caking at the bottom.

NERVE-SUTURE.

IN the clinical notes of the *British Medical Journal* of October 8 is reported a case, operated on by Mr. Croft at the St. Thomas Hospital, in which the tibial and femoral arteries and the posterior tibial nerve had been cut by a stab. The ends of the posterior tibial were found retracted an inch and a half, but were carefully sutured together with very fine silk and the wound dressed antiseptically. Twenty-four hours afterwards "sensation was observed to be present all over the foot, but modified in character in the sole." Five weeks later the leg was entirely well, the boy having perfect use of, and perfect sensation in, the foot and leg.

A NEW THERAPEUSIS IN EPILEPSY.

ANY person who shall discover or invent a method for treating epilepsy which shall cure even a moderate percentage of cases will be a great benefactor, not only of the human race but of the ordinary neurologist, whose sympathies are often excessively worked upon by failures to bring decided relief under circumstances most pitiable. It is, therefore, with great desire, although with much incredulity, that we approach the subject of the method of treatment of epilepsy devised by Dr. George T. Stevens, of New York. The central idea of this plan of treatment is that a large proportion of cases of epilepsy, as well as of chorea and of other forms of nervous disorder, are due to an unsuspected weakness of some of the optic muscles, which produce perpetual irritation by the excessive effort necessary to bring the ocular axes into unison. We understand that Dr. Stevens has prepared an elaborate work upon this subject, which will soon be before the medical world. Until this has appeared we do not propose to discuss the subject in detail, but simply to call attention to it. In an article in the *Medical Bulletin* for September, Dr. Ambrose Ranney confirms the work of Dr. Stevens. In order to correct the small degree of insufficiency which produces these nervous irritations, it was necessary for Dr. Stevens to invent a new operation, as the older plan of entirely severing the muscle is almost always followed

by an excessive result. This operation in the main consists of making a small opening through the conjunctiva, exactly over the insertion of the tendon, when the tendon is seized by extremely fine forceps, and divided in each direction, preserving the extreme outer fibres, or, at least, the reflection of the capsule of Tenon, which serves as an auxiliary attachment.

THE DOCTOR'S CARD.

IN a recent number of the *Canada Medical and Surgical Journal*, Dr. William Osler calls attention to the subject of doctors' cards. The subject may seem a trifling one, and yet the spirit of quackery may be revealed in the doctor's daily card as well as in his door-plate. The English physician usually has upon his card his name alone, with perhaps the address of his house or club. The American physician's card is apt to be large and boldly printed, and sometimes contains his titles or official positions, and still more frequently his address and office-hours. The door-plate is usually a reflex of the card. The principle involved in each of these methods of making the identity of the doctor known is, according to our thinking, the same. In each instance the desire should be to afford knowledge to those who are seeking it, rather than to attract the attention of those whose ears have not been already tickled by the fame of the physician. The door-plate should be inconspicuous, and yet not hard to find. The card should be modest, and always engraved instead of printed, and contain no titles other than that of doctor. As a direction to patients, the office-hours should be placed in the corner of the card. When this is done, the card becomes a purely business card, and no one who closely studies the proprieties of life would leave such a card upon social occasions. The doctor should, therefore, have two distinct cards,—the visiting and the professional card.

SANTONIN.

FEW Anglo-Saxons have been more energetic or more willing to take risks than the Russian traders, Messrs. Ivanoff and Sawinkoff, who, in 1883, followed the Russian arms in Turkestan by transporting, nearly

three thousand five hundred miles on camels' backs through a dreary steppe, the machinery for the preparation of santonin. They are said to have spent between them three hundred and twenty-five thousand dollars in this work; and when the difficulties of communication between Turkestan and Nijni Novgorod, the nearest central station, are remembered, the boldness of these financial princes will be clearly seen. The hydrochloric acid used has to be carried in wagons two thousand miles across the wastes and deserts. Out of sixty tons which were sent in one wagon-train of one hundred and seventy wagons, no less than thirteen tons were said to have been lost by breakage. Formerly nine hundred to a thousand tons of the flower-heads of *Artemisia maritima* were yearly sent to Novgorod, *en route* to Western Europe. All this traffic is put an end to, save only as regards so much of it as is intended for the United States, the very heavy import duty upon santonin in this country preventing the importation of the manufactured article. The Turkestan works are said to have turned out ninety thousand pounds of santonin in 1885, of which the Japanese are affirmed to have taken fifty thousand pounds. Either the Japanese intestine must be a most extraordinarily rich soil for worms, or the people must employ the remedy for purposes not known to Western civilization.

AVELOZ.

IN the United States consular reports for October, 1884, attention was called to the use of the juice of aveloz in Pernambuco as a remedy for the treatment of cancer. The plant which yields it is said to belong to the family of Euphorbiaceæ, and to have been described in 1875 in Martin's "*Flora Brasiliensis*" under the name of *Euphorbia heterodoxa*. It is used as a local application, and is asserted to have been found especially valuable in the treatment of epithelioma. In sarcomatous and carcinomatous diseases it has not yielded so good results. In order to keep the juice, it is mixed, when fresh, with salicylic acid, which is said to preserve it without affecting its medical properties. Most of the Euphorbaceous plants contain an acrid juice, which is powerfully irritating to raw surfaces, or even escharotic, and of such nature seems to be the remedy in question. Its value has been confirmed by Dr. J. E. Janvrin in the "*Annals of Gynecology*," vol. i. No. 1. He has obtained

excellent results from its employment in epitheliomatous uterine diseases. He says he prefers it as a local application to any other escharotic in such cases of epithelioma of the cervix as are not far advanced, and in which for any reason it has been decided not to extirpate either the cervix or the entire uterus.

Even when the disease is so far advanced that any other operation than curetting is contraindicated, the application of aveloz once or twice a week has proved very effective in diminishing pain (after the immediate pain produced by the application has ceased), and in decreasing the quantity and offensiveness of the discharges, thus prolonging the life of the patient, and making her presence much less objectionable, for a while at least, to those in constant attendance upon her.

GLEDITSCHINE.

OUR readers will remember that in our August and October numbers we expressed editorially some doubt as to the genuineness of the so-called gleditschine. This suspicion has been abundantly confirmed during the last month. The solution has been analyzed by three chemists, entirely independently of each other. Mr. F. H. Thompson, chemist of Parke, Davis & Co., published his article in the *Medical Age*, Professor F. G. Novy published his in the *Pharmaceutische Rundschau*, and Dr. John Marshall, Demonstrator of Chemistry in the University of Pennsylvania, his in the *Philadelphia Medical News*. The analyses are substantially in accord in showing that the solution sold as a two per cent. solution of the new alkaloid contains about six per cent. of cocaine salt, and, besides, some atropine or other alkaloid of the mydriatic group.

In connection with this subject it is very interesting to note that in 1878 (*Philadelphia Medical Times*) Dr. B. F. Lautenbach made a chemico-physiological study of extracts made from the fruit *Gleditschia triacanthæ* and *G. ferox* as growing in the parks around Geneva. These extracts he found to produce in the frog stupor and a loss of all reflex activity. That this loss was due not to an influence exerted either upon the motor or sensory nerves was proven by the fact that it was not prevented by tying the artery of a leg, and thereby shutting off access of the poison to the muscles and nerves. It must, therefore,

be spinal. Dr. Lautenbach did not make any study as to the possession of local anæsthetic properties by this alkaloid, although the contrary has been asserted by one or two observers. He obtained the alkaloids in the form of rhombic crystals, almost completely insoluble in water, but readily soluble in alcohol, capable of forming salts with acids, and acting upon frogs precisely as did the extracts. To this alkaloid Dr. Lautenbach gave the name of gleditschine.

THE INDEX CATALOGUE.

THE appearance of the eighth volume of this gigantic work shows that Dr. Billings and his associates are still persistently laboring on, and strengthens the hope that the time may come when the whole work shall have reached temporary completion. The growth of medical literature is so rapid that, even if the "Index Catalogue" does catch up to the library at Washington, volume after volume must still appear to keep the work abreast of the ever-advancing tide. The present volume includes thirteen thousand four hundred and five titles, twelve thousand six hundred and forty-two subject-titles of separate books and pamphlets, with twenty-four thousand one hundred and seventy-four titles of articles and periodicals, and is said to mark the completion of the first half of the work.

BIDENS BIPINNATA.

THIS common weed, usually known as beggar's tick, or Spanish needle, has long been used as a remedy in asthma and bronchial catarrhs by irregular practitioners in the United States, but, so far as our knowledge goes, has not attracted the attention of the regular profession, although mentioned in the United States Dispensatory. In a letter recently received by Dr. C. R. Gaul, of Jacksonwald, Pa., it is stated that he has employed the remedy (in the form of a decoction) with extraordinary success for the relief of hay-asthma. If any of our readers can give further information on the subject we would be obliged for a communication.

Reports on Therapeutic Progress.

DIAGNOSTIC VALUE OF THE GONOCOCCUS IN GONORRHOEA IN WOMEN.

According to the Swiss correspondent of the *British Medical Journal* for October 15, 1887, DR. CONRAD, at the spring meeting of the Medicinisch-Pharmaceutischer Bezirksverein of Berne, read an able paper on Neisser's gonococcus and its diagnostic value in female cases of gonorrhœa. Is it possible to differentiate a gonorrhœal affection of the female genitals from a non-gonorrhœal one by means of the microscopical examination of secretions and cultivation experiments? Such was the problem the author laid before himself, and tried to solve by special researches of two and a half years' duration. Dr. Conrad carried out his valuable researches in the following way. Having come across a case of acute, purulent, or mucoid catarrh of the vagina, womb, or urethra, where the affection had again and again recurred, or been followed by a very acute or chronic inflammation of the genital tract, or where there was a more or less clear history of gonorrhœal infection, he gathered (with due precautions and at several different times in every case) some discharge from the deeper portions of the cervix and urethra, and then subjected it to the bacterioscopic examination, conjointly with Drs. Emmert, Jr., Von Freudenreich, and Sahli, the observers (all experienced bacteriologists) working independently of each other. Sixty cases of supposed gonorrhœa were carefully studied after that plan. Only in five recent and in two chronic cases were characteristic groups of Neisser's microbe detected; in several other instances only a few isolated gonococci were found; in many other patients numerous bacilli and cocci could be seen, which by some authors are regarded as constant satellites of Neisser's micro-organism, but which also occur alone in chronic simple catarrhs. Cultivation of the discharge from twelve cases (including those where the gonococcus had been found) gave entirely negative results (the nutritive media employed being agar-agar and Kemerisch's peptone gelatin). The general conclusions arrived at by the author are these: 1. Detection of the gonococcus succeeds more easily and more frequently in men than in women. It is so because the latter (a) experience comparatively less discomfort from acute gonorrhœa, where the microbe is most frequently demonstrated; (b) they generally

seek medical advice and help far later than men; (c) as a rule, they pass water before undergoing a gynæcological examination and thus wash away or dilute their urethral discharge; (d) they sometimes come to be examined only after some treatment by injections or other local means. It is possible also that the detection becomes more difficult in consequence of gonococci being destroyed by micro-organisms of other species, which often grow luxuriantly in discharge of genital mucous membranes, "the female genital tube being a true natural incubator (*brutofen*) favorable to any bacterial growth." 2. While in recent cases of female gonorrhœa Neisser's gonococcus may be almost always detected, it cannot possibly be found in many chronic cases. 3. Hence both acute and chronic gonorrhœal affections may be present in women, in spite of our inability to demonstrate the pathogenic microbe in a given case. If so, the gonococcus may have only a limited diagnostic value, the practitioner being often compelled to rely only on etiological and clinical facts. Nevertheless, the practitioner must undertake a bacterioscopic examination as often as possible in every individual suspicious case, since detection of the microbe is of paramount importance as regards diagnosis, prognosis, and treatment of the case. In addition, Dr. Conrad states he obtained satisfactory results from treating (1) gonorrhœal catarrhs of the female genitals by vaginal injections of acetum plumbi, sulphate of zinc, and corrosive sublimate (1 to 2000); (2) very obstinate cases by dressing the vagina with iodoform, iodol, zinc milk, and salol gauze, as well as by "Paquelinizing" (*Paquelinisirung*) erosions; (3) urethritis by the internal use of santal oil (in gelatin capsules); (4) chronic gonorrhœal uterine catarrh (without any further complications) by *raclement*, with subsequent intra-uterine injections of tincture of iodine. Supreme importance, however, should be ever attached to prophylaxis. The strictest surveillance over prostitution, prohibition of marriage and coitus to every gonorrhœal male patient until every trace of discharge has disappeared; an urgent appeal to every man of the kind that he should not neglect his (chronic) affection, however slight, but should submit to treatment till he is completely cured (since otherwise he will most cruelly sin against his wife and children). Those are preventive measures against formidable prevalence of gonorrhœa, most justly and forcibly insisted on by the author; justly, because chronic gonorrhœa is but only too

often regarded by non-medical men as of no importance, and that not only in Switzerland, but also in other countries. In the course of a prolonged and interesting discussion which Dr. Conrad's paper gave rise to, Drs. Emmert, Dick, and Sahli and Professor Demme also expressed their belief that while the gonococcus can, with certainty, settle the question in regard to a specific nature of the case, a negative result of the bacterioscopic examination by no means excluded gonorrhœa. Dr. Emmert pointed out that the outcome of his and Conrad's researches seemed to pretty well coincide with that of Welander's, a Swedish practitioner who had published his observations in 1884. Especially Dr. Emmert drew attention to the fact that the genuine habitat of the gonococcus appeared to be discharge of the urethra, and not that of the vagina, since, when the microbe was found in the former, artificial inoculation of the vaginal mucous membrane almost invariably produced gonorrhœal vaginitis, while inoculation of the vaginal discharge from a gonorrhœal woman in the vagina of a healthy one had no bad effect. Dr. Dick mentioned that he obtained satisfactory results from treating female gonorrhœa by a two per cent. solution of thallin (as recommended by Professor Goll, of Zurich; see the *Journal*, May 21, 1887, p. 1133). Professor Demme stated that he, while experimenting after all possible methods, was unable to obtain any cultures of gonococci. Hence he doubted whether Professor Kreis (who had been able easily to cultivate the microbe in agar-agar) had had to do with a true gonococcus. The same opinion was expressed by Dr. Tavel. Dr. Sahli asserted that the microbe could not be demonstrated very often even in such female cases where it mattered about gonorrhœa with certainty, or at least with a great probability. Thus, he was not able to detect it in a patient with a profuse purulent vaginal discharge, who had been recently infected by a man with a typical gonorrhœa and with masses of gonococci in his urethral discharge. Only some extracellular diplococci were discovered in the woman. Dr. Sahli ascribes the difficulties which beset the detection of gonococci in female cases mainly to the possibility of their being crowded out by other vaginal fungi of non-pathogenic and "half-pathogenic" varieties. By "half-pathogenic" (*halb-pathogene*) the author means bacteria which give rise to inflammatory processes only when they are present in considerable quantities, or when the system is already weak-

ened or injured in some other ways. (As an example of such "half-pathogenic" microbes, Dr. Sahli adduces bacteria occurring in catarrhal pneumonia: they are purely saprophytic; but when the inner surface of the lung is damaged by bronchitis, they begin to grow luxuriantly and set up inflammation, partly by mechanical irritation and partly in virtue of a chemical action of their metabolic products.) As to male cases of chronic gonorrhœa, the author denies that Neisser's microbe was often absent in them. At least, having examined a number of cases of the kind, he was invariably able to detect the gonococcus, even after a very prolonged existence of the disease.

DECOCTION OF LEMON IN INTERMITTENT FEVER.

DR. R. A. LANCASTER, of Gainesville, Fla., writes in the *Medical Record*, October 8, 1887, as follows: "For two years or more I have been using the decoction of lemon, as recommended by Dr. Crudeli, for the prevention and the cure of intermittent fever. In many cases it acts 'like a charm,' even where quinine and arsenic have failed to prevent frequent returns of the chills. It is especially serviceable in that class of patients that we sometimes meet with, who cannot take quinine without experiencing such unpleasant symptoms as urticaria, nausea, headache, nervousness, etc. In my experience the lemon decoction has proved much more efficacious than arsenic in preventing the recurrence of the chills after they have been broken with quinine, and in one case, at least, it promptly relieved the chills where large doses (twenty grains per day) of quinine had failed to do so. About twelve months ago, Patrick M—— applied to me for treatment, declaring that he had had a chill and fever every day for a week, although he had been taking daily, under a physician's directions, twenty grains of quinine and thirty drops of Fowler's solution of arsenic. I stopped the quinine and arsenic and put him upon the lemon decoction, and the result was prompt relief. I met the same patient again a few days since, and he told me that he had several times had a return of the chills, but they were always promptly relieved by the lemon. He said that he had never had a chill upon the same day on which he took the lemon. In quite a number of cases where there had been a recurrence of the chills on the seventh, fourteenth, or twenty-first days, this habit was broken up by

using Dr. Crudeli's remedy two or three days each week. My usual plan for treating the intermittent type of malarial fever—and it has been very successful—is to give, when first called, a mercurial purge; I then direct quinine—from five to twenty grains, as may be necessary to prevent the paroxysm—to be given at one dose five hours before the expected chill; every morning thereafter, until the patient is considered cured, I direct the lemonade, *à la* Crudeli, to be taken before breakfast. Of course, anæmia, engorgement of the liver and spleen, or any other of the sequelæ of malaria must receive appropriate treatment. The greatest objection I find to the lemon treatment is the difficulty of getting the patients to carry out the directions. They think them too simple to seem to be very important."

TREATMENT OF HECTIC FEVER.

It has been only since the careful bedside observations of Wunderlich that the thermometer has played such an important part in fevers, and the great value of carefully recording the fluctuations of the temperature been fully realized. The treatment of fevers varies to a great extent. Quinine and salicylic acid are old "stand-bys;" then later kairin and thallin came into use; then acetanilide, or the so-called *antifebrin*.

The success which attended the use of these drugs, so far as lowering the temperature was concerned, caused at first, naturally enough, their practical value to be overrated.

Our experience with hectic fevers, such as usually accompany chronic tuberculosis, is even less favorable than with fevers of the typhoid type. Indeed, but a few years ago, no other remedy was thought to be of any avail but quinine. Hydriatic treatment was seldom, if ever, resorted to, on account of the dangerous accompanying and after-symptoms.

The remedy most frequently used in such cases is antipyrin in doses of about 0.5 gramme ($7\frac{1}{2}$ grains) to 1 gramme (15 grains).

PROFESSOR ALFRED PRIBRAM, in an article in the *Prager Med. Wochenschrift* on the treatment of hectic fevers, speaks of his experience with the drug, and states that he has found smaller doses of far greater value.

He considers a long-continued use of antipyrin inadvisable. Under its use the temperature will sometimes fall to subnormal,

and he calls special attention to the fact that the lower the temperature is reduced by full doses of the drug the next rise will be proportionately higher.

Some cases which the writer cites show a rise and fall of over three degrees Centigrade daily.

The author advises the following treatment, which, he contends, will yield the best results:

A tablespoonful of a one per cent. solution of antipyrin contains about 0.15 gramme ($2\frac{1}{4}$ grains) of the drug, and the same amount of a one and one-half per cent. solution contains about 0.23 gramme ($3\frac{1}{4}$ grains). When first trying the effect of antipyrin on hectic fevers one should give about two tablespoonfuls of the one per cent. solution (less for a child or aged person) about half an hour before the fever begins. Then carefully watch the temperature, and note if the rise is less than usual. If the rise is above 38° C., then give another tablespoonful of the solution; and this should be done every hour until the temperature falls below 38° C. Usually two doses will prove sufficient. If the one per cent. solution seems strong enough, it should be continued in the same manner for four or five days; if not, the one and one-half per cent., or even a two per cent., solution may be used in its place. On the sixth or seventh day begin to omit one dose daily, viz., the last one (that is, if you have been giving three doses daily, omit the third dose). The results will usually continue to be the same. Then continue this treatment for a few days longer, then drop another dose, and proceed again in the same manner, keeping meanwhile careful record of the temperature. Soon the remedy may be stopped entirely, without changing the temperature. Continue, however, the observations, as possibly the temperature will rise again, owing to severe coughing, overloading of the stomach, or during menstruation, in which case antipyrin may be commenced again, and given in the same manner as indicated above. The appetite generally increases, and strong nourishment should be given.

Professor Pribram gives numerous cases which show the good results of his method in using the drug.

In those cases which cannot bear even small doses of antipyrin, when its use causes profuse perspiration, or where there is a tendency to hemorrhage, acetanilide (antifebrin) may be used in its place, and in the same manner, with similar results.

ANTIPIRYN AND ANTIFEBRIN IN HAY-FEVER.

DR. W. CHEATHAM, of Louisville, Ky., writes to the *Medical Record*, October 8, 1887, as follows: "This being what is known as 'hay-fever' season, I wish to call the attention of the profession to the use of the above drugs in this affection. I do not remember seeing any article on the subject. I used antipyrin frequently last summer and fall, always with the best results. This summer I have been, and am now, using it in a number of cases, and have been also trying the antifebrin. Mr. B——, foreman in a large railroad repair-shop, has had so-called hay-fever for ten years; the difficulty begins with him in early spring, and ends with cold weather. He has taken, during the whole summer, a daily dose of fifteen grains of antipyrin, which has given him great comfort, relieving him entirely of all the fever symptoms, stimulating him for work, giving him good rest at night, and lessening very much all nose and eye symptoms. I used it last summer in fourteen other cases, with similar results. This summer I have tried the antifebrin in half of my cases. The effect has been about the same as from antipyrin. In a few of the cases some slight depression was complained of, but this is readily corrected by small doses of belladonna or its alkaloid. As I stated before, some of my patients have taken both the antipyrin or antifebrin (more frequently the former) daily—from ten to thirty grains of the former, or from four to six grains of the latter—for several months, with no bad effects. I know it to be of great benefit in hay-fever, and am anxious for others to try it."

THE ACTION OF VERATRINE.

The physiological action of veratrine was investigated many years ago by Prévost in France, Guttmann and Bezold and Hirt in Germany, and Amory and Webber in America. More recently Boehm, Fick, and Rossbach in Germany, and Ringer and Brunton and Cash in England, have added to our knowledge of its influence on the muscles and heart.

For the purpose of confirming or refuting previous observations, LISSAUER, under the direction of Boehm, has carefully re-examined the effects produced by veratrine on various organs, and published his results in the *Arch. f. Exp. Path. u. Pharm.*, xxiii., Heft 1 and 2. We take the following from the analysis of his paper published by Dr. Leech in the

Medical Chronicle for September, 1887: He used in his experiments crystallized veratrine. Its action, he says, does not differ from that of the amorphous veratrine of the German Pharmacopœia, which consists of a mixture of cevadine, a crystallized alkaloid, and veratridin, an amorphous base. Concerning the influence of veratrine on the muscles of cold-blooded animals, Lissauer made no special investigations, because of the general agreement which prevails as to the phenomena observed. He is inclined to think, however, that the motor phenomena produced by veratrine, though chiefly dependent upon its action on the muscle, are also influenced first by stimulation and then by paralysis of the cord. He is thus in accord with Kölliker and Guttmann, but his views are founded rather on inferences from what he has observed in warm-blooded animals than on direct experiment. In the dog, and to a less extent in the rabbit, he saw veratrine produce first an ataxic condition, which, from previous experiments of Rossbach and the character of the motor disturbance which he noted, he attributed to the increased irritability and altered contractility of the muscles caused by veratrine. Afterwards he says he noted a paralytic convulsive stage, and this he considers centric in character. The reasons which he gives for this view, however, are not quite clear and convincing.

On the frog's heart, veratrine, he finds, produces first a decrease of pulse-frequency, then peristaltic movement (*Herzperistaltik*), followed by strong and slow ventricular contractions. In the isolated heart the contractile power of the ventricles as estimated in Williams's apparatus seems at first increased and then decreased. The slowing influence of veratrine is seen when the heart is isolated as well as when it is *in situ*. In his experiments on warm-blooded animals Lissauer was unable to obtain the increased rapidity of heart's action and rise of pressure which Bezold and Hirt state they saw after small doses. He found the pulse slowed and the pressure decreased, though during poisoning by veratrine irregularities in pressure and frequency occur. He thinks it is possible, as Bezold and Hirt affirm, that veratrine stimulates the vagus centre, but the slowing of the heart is chiefly due to the direct influence of the drug on the motor ganglia or muscle; the slowing is not accompanied, when ordinary doses are given, by loss of power of the contraction. Bezold's and Hirt's experiments seem to indicate that veratrine first stimulates

and then paralyzes the vaso-motor centre. Lissauer finds no evidence of stimulation. The most important effect of veratrine is due to its paralyzing influence on the vaso-motor system, but whether this is central or peripheral he is unable to determine. Lissauer finds, like earlier observers, that veratrine produces slowing, temporary intermission, then cessation of respiration; a slight acceleration at first noted is due to the psychical excitement produced by the experiments. Atropine directly antagonizes the action of veratrine on the respiratory centre, and when the two drugs are given together life is longer sustained than when veratrine is given by itself.

RAPID ANÆSTHETIZATION.

In the *New York Medical Gazette* of October 22, DR. J. LEONARD CORNING makes a suggestion, which seems to be based upon sound principles, and may occasionally be of avail in hastening the action of an anæsthetic. Noticing that small men were intoxicated by much less quantities of alcohol than was required for men of great bulk, he conceived the idea of reducing the quantity of blood to be saturated by the anæsthetic, and thereby increasing the intensity of the action of the drug in a certain length of time. In a case of difficult etherization, owing to habits of intoxication, a strong, flat, elastic tourniquet was secured around each of the patient's thighs, so as to arrest both the arterial and venous blood-flow in the same. By this procedure each limb was converted into a receptaculum for a considerable proportion of the total blood-mass, or, as a bystander "put it," "about one-third of the man was cut off," and consequently it was only necessary to saturate the remaining two-thirds (of the total blood-mass). The result was very satisfactory, and after the operation, which was a brief one, when the ligatures were removed, the patient recovered from the effects of the ether instantly. Dr. Corning states that if he has again occasion to test this method of introducing general anæsthesia, he intends to ligate the arms as well as the lower limbs, and place the ligature as near the axilla as possible.

PROPOSED CHEMICAL LUNG TEST.

DR. ZALESKI, of the Dorpat Physiological Institute, has published in the *Vratch* (No. 32) an account of some researches he has been

making with the object of introducing a new lung test, which may be trusted to give satisfactory results in cases where the hydrostatic test is inapplicable or of doubtful value. He suggests that, as at the moment of birth there is not only an influx of air into the lungs, but a very marked increase in the blood circulating through them, and as blood contains iron in a tolerably definite proportion, the quantity of iron found in the lungs should furnish a clue to the question as to whether the child had breathed or not. He examined the lungs of four still-born children and of three children born alive; also those of a healthy man who had been killed by an accident. Having of course taken care that the lungs had not been subjected to any previous section or manipulation, he tied the roots and cut off the bronchi. They were then immersed in distilled water for the hydrostatic test, and, after being dried with filtering paper, they were weighed in a platinum dish, and sections were made and carefully examined. After this they were dried in a hot-air chamber at from 115° to 120° C. until they ceased to lose weight. Soda was added to the dried lung-substance, also water, and the whole was dried in a water-bath. The mass was then ignited in a Bunsen's burner, treated with water, and thrown on a filter, which gave no ash. The whole was then again ignited. Here, all the iron was, of course, not in the filtrate. It was then heated with strong hydrochloric acid in a water-bath. After the hydrochloric acid had evaporated, the residue was treated with sulphuric acid, reduced by zinc, and the iron estimated by a solution of permanganate. The result of the observations showed that the iron contained in the lungs of children that had breathed was always considerably more in proportion to their weight than in the lungs of still-born children. The mean percentage of iron (Fe) in the lungs of the still-born was 0.0110 of the weight of the fresh lung, and 0.0828 of the dried lung; whereas the mean percentage of iron in the lungs of the children who had been born alive was 0.0188 of the weight of the fresh lung, and 0.1182 of that of the dried lung. The iron in the case of the adult was still more than in that of the infants, the percentages being 0.0217 and 0.1266 of the fresh and dried lung-substance respectively. In one case in which the child had lived for five days part of the left lung was found diseased, there being evidences of septic pleuritis and pneumonia. Here the diseased portion of the lung was separately examined, and found

to contain a percentage of 0.0192 of iron in the fresh state, and of 0.1197 in the dry state, so that it would appear that the "iron lung test" holds good even for diseased lungs. The author has not made observations in cases where there has been profuse hemorrhage from the cord, nor in those where putrefaction has commenced, but he thinks it probable that the test would answer here as well as when the lungs have been immersed in spirit. Of course, artificial inflation after death would not vitiate the test, as was indeed proved by one of the cases where Schultze's method of inflation was adopted five hours after still-birth. Dr. Zaleski's "iron lung test" is evidently of too complicated a nature to be carried out by the ordinary practitioner, but in doubtful cases it would be quite practicable to preserve the lungs and send them to an expert, just as the stomach and other viscera are sent in poisoning cases. Before, however, any real value can attach to evidence deduced from it, a large number of experiments must be made by different observers, and their results collated.—*Lancet*, October 15, 1887.

THE USE OF MENTHOL IN TUBERCULAR LARYNGITIS.

At the meeting of the Cincinnati Academy of Medicine, DR. JAMES G. HYNDMAN read a paper (*Cincinnati Lancet-Clinic*, October 8, 1887) on the use of menthol in tubercular laryngitis, a drug which was first used in this connection two years ago by Dr. Rosenberg, of Berlin.

Rosenberg's attention was first directed to this use of menthol by observing the anæsthetic and analgesic influence it exerted upon the nasal and pharyngeal mucous membranes. This led him to its employment in the larynx, especially in the ulcerative stage of tubercular laryngitis, and a very extended experience has shown that it is well borne. The first sensation produced is that of a slight tingling, followed by a pleasant cool feeling. After the first few sprays cough is seldom excited. Rosenberg advises to apply the agent by means of the laryngeal syringe, guided by the mirror. Dr. Hyndman has found the spray apparatus in general use preferable, the force being that of a chamber of compressed air. Attempts at gargling kept up by the patient secure contact of the dissolved menthol with all parts of the diseased tissue of the larynx.

The writer's experience with the use of

this agent is limited to five cases, two of them well advanced, but his results are singularly corroborative of Rosenberg's eighty cases (including some pulmonary patients). In a comparatively short time (from one-half to one week) there was marked subjective improvement, with diminished dysphagia, increased hopefulness, and improved nutrition. The changes in the local processes reported by the author were striking. The ulcerations rapidly lost their dirty gray appearance, and fresh, healthy granulations were set up, resulting, in a time varying from two to ten weeks, in perfect cicatrization. The thickened and infiltrated mucous membrane did not respond until lactic acid applications were made. While the latter possess the advantage of much more rapid action on local ulcerations, they are at the same time far more painful.

In hospital cases it may be possible to follow the directions to make these applications twice a day in the earlier part of the treatment. But in private and dispensary practice it is seldom that we can see our patients oftener than once in twenty-four hours.

The sedative effect of the menthol lessens dysphagia, and thus promotes nutrition, the first application securing comparative ease for several hours, and the next for a still longer time. Finally, one application daily will secure the patient moderate relief. The solutions employed may be either oily or alcoholic, Dr. Hyndman never having found the alcoholic solution to produce pain. In fact, he prefers it to the solution in oil, since the latter requires a troublesome warming of the receptacle, or its application by the syringe. The strength of the solution may vary from five to twenty per cent., fifteen per cent. being well borne. In many of his cases Dr. Hyndman states that a year has elapsed without the development of further tubercular symptoms, though it may be that a sufficient time has not yet passed to enable one to pronounce positively that cures have been effected. Notwithstanding the excellent results which have so early followed the local treatment, and the apparent healing of ulcers and improvement of the general system, it would certainly be the course of wisdom to continue the treatment by inhalations, or very forcible sprays, for a long time, in the hope of exerting the same fatal action upon tubercle-bacilli possibly present in the deeper air-passages. The experiments made by Reichert, of Rostock, consisting of throwing spray of saffron deep into the open tracheæ of living

animals, and then, the animals having been killed, finding the discoloration in the terminal divisions of the air-passages, would seem to show conclusively that good results can be obtained in pulmonary tuberculosis by antiseptic inhalations of sprays. Not only is it theoretically proved, but the narration in the address referred to of a number of apparent cures would seem to place this plan, if not this particular agent, in the first rank.

The theory of the action of menthol is simple. Koch found that *ol. menth. pip.*, of which menthol is the active constituent, prevents further development of anthrax bacilli in the proportion of 1 to 33,000, and kills cholera bacilli 1 to 2000. Experiments made in Koch's laboratory have shown that menthol introduced into pure culture of tubercle-bacilli caused their destruction.

Again, its action on tubercle-bacilli is shown by the experiments of Sormain and Bagnatelli, who mixed one cubic centimetre of tubercular expectoration with the antiseptic (proportion not stated), and watched it for one to two hours at a temperature of 35° to 40° C. (95° to 104° F.). They then injected it, by means of a disinfectant syringe, into guinea-pigs, without any infection resulting.

Our hopes from the use of menthol in this class of cases are founded, therefore, not only upon experimental evidence, scientifically as it has been built up, but also upon a favorable report of its clinical utility based upon a very considerable experience. If it be true, as claimed for it, at the present time there is no other effective antiseptic agent known which can be introduced into the organism in so concentrated a solution, and for so long a period, without risk or danger to the general system, menthol certainly deserves an extended trial.

CHAMPNEYS ON ARTIFICIAL RESPIRATION IN INFANTS.

In a very excellent little monograph on this subject, recently published, DR. CHAMPNEYS, after a number of experiments on infants in whom no attempt at respiration had taken place, arrives at the following conclusions: "Never hurry; it is not a question of seconds, and success depends upon a fine exercise of the judgment. Make a good diagnosis first as to life or death; secondly, as to the stage of asphyxia. If the heart beats ever so slowly and feebly, the infant is not dead. If the heart is not beating death is not certain, unless it can be proved to be inactive for

some time. If the child is livid and not flabby, it will probably come round; wipe out its mouth and pharynx, and rub it with a soft cloth down the spine; press gently on the cardiac region. If this produces no effect, or if it be in the pale stage, inflate the lungs by the mouth and then by Silvester's method. If air enters the lungs, well and good; if not, try Schultze's method, or insert a catheter as described above. On the first sign of muscular action, plunge the child into cold water, or into alternate hot and cold baths. Vary the treatment between occasional inflation of the lungs, artificial respiration, pressure over the cardiac region, baths, irritation down the spine, according to the judgment, remembering what may be expected of each method, and that no one method will suffice for all cases. Watch for signs of resuscitation,—namely, improvement in color, in movements, in cardiac pulsations, as described above. Never be content until the child breathes regularly and appears to be continually improving."—*Medical Press*, October 5, 1887.

WHOOPING-COUGH TREATED BY NASAL INSUFFLATIONS.

In the *British Medical Journal* for October 15, 1887, MR. GEORGE HOLLOWAY gives a brief account of twenty-four cases of whooping-cough treated with insufflations of boric acid, according to the plan first proposed by Dr. T. Guerder, of Paris. Dr. Guerder's treatment is based on the theory that whooping-cough is due to nasal reflex action (of parasitic origin), caused by congestion of the pituitary mucous membrane and nasal catarrh. The congestion of the respiratory tract in this disease always commences in the Schneiderian membrane, and extends from it to the other parts, partly, perhaps, from the multiplication of the germs and partly from the incessant cough, which produces chronic congestion of the mucous membrane of the air-passages. In support of this statement Mr. Holloway states that if the congestion of the Schneiderian membrane be relieved by the application of boric acid, congestion of the other parts disappears also.

As yet no essential germ of this disease has been satisfactorily demonstrated, but from its infectious nature there can be little doubt but that it is due to a specific germ, and Mr. Holloway believes that the favorable results which he has obtained from the use of boric acid are due to its action as a parasiticide. The

method of treatment which he advises is as follows: He confines the patient to one room for one week or ten days, and instructs that each nostril be insufflated every three hours during the day, and once during the night, with from 2 to 3 grains of finely-powdered boric acid. No difference is made in the diet unless there is some special circumstance which calls for it, and at the end of ten days the child may be allowed to go out in favorable weather. The average duration of the twenty-four cases which Mr. Holloway reports seems to have been about three weeks,—a great reduction in the usual duration of the disease.

HYDRASTINE AND BERBERINE.

PROFESSOR SCHMIDT publishes some further information respecting the remarkable resemblance of hydrastine to narcotine in its behavior to oxidizing agents. Last year (*Pharm. Journ.*, 3, xvii. 427) Messrs. Freund and Will stated that upon treating hydrastine in acid solution with oxidizing agents it splits up into opianic acid, and a base closely resembling cotarnine, which appears to have been since named hydrastine. Professor Schmidt now states that if the oxidation be effected in alkaline solution the decomposition goes further, the products being hemipinic and nicotinic acids. Notwithstanding this complete correspondence in behavior, all attempts to convert hydrastine into narcotine, or *vice versa*, have hitherto failed. It is further affirmed by Professor Schmidt that, although hydrastine crystallizes from acetic ether in very large crystals, it does not form any well-crystallized salts except the picrate, the salts being usually of syrupy consistence, drying up to a horny substance of inconstant composition. He, therefore, infers that the commercial salts of hydrastine are not of constant composition, and probably are mostly basic compounds.

With berberine and its salts the conditions are exactly reversed, the alkaloid being difficult to obtain in a crystalline form, while its salts are really crystallizable. On this ground Professor Schmidt questions the character of the substances described in price-lists as "berberinum purum," which he is reported to have stated always contains chlorine (*Pharm. Zeit.*, September 24, p. 542). He says that berberine has a remarkable power of combining with solvents, such as alcohol, ether, chloroform, and acetone, to form crystalline compounds. Thus, berberine and chloroform, in the proportion of one molecule of each, form a beau-

tiful crystalline body, which is not a simple addition product, since it is permanent at 100° C., and by acids is decomposed, not simply into berberine and chloroform, but decomposition products of the latter. Berberine can also combine with a second molecule of chloroform, but this behaves like water of crystallization.—*Pharmaceutical Journal and Transactions*, October 1, 1887.

REMARKABLE CASE OF ANTIFEBRIN-POISONING.

The following extract is from a letter addressed to the *Deutsche Medicinal-Zeitung* by DR. DOLL, of Berlin:

"The extensive uses of antifebrin in the practice of medicine, and its universal employment for neuralgia, toothache, headache, and the like, compels me to bring the following case of antifebrin-poisoning (the only one to my knowledge) before the profession:

"Mrs. D., who suffered from nervous headache, advised by an article in the *Berliner Lokalanzeiger*, purchased twenty-five pfennigs' (about six cents) worth of antifebrin, and put the entire quantity in two portions, which she drank in close succession.

"In about three hours vomiting began, and a cold sweat broke out all over the body, and the patient sank into a deep faint.

"Several hours subsequently I was called in, and found the face, ears, chest, hands, and feet as cold as ice, and covered with a cold sweat; the abdomen was warm but moist; the face deathly pale; eyelids closed, but when spoken to she would open her eyes; pupils moderately dilated, and showing but little sensitiveness to the light; heart beating violently; respiration rapid; pain in abdomen; nausea, with occasional retching, but no vomiting.

"The nervous system was in a most strange condition, for, although the woman lay perfectly unconscious of her surroundings, yet she was able to answer to all my questions promptly and sensibly, although only in a weak voice.

"She said that she felt as though she were continually falling, and that she felt perfectly numb.

"In the morning, after the continued use of strong excitants during the night, consciousness returned, accompanied by a most profuse perspiration. At nine o'clock the temperature was normal; the pulse was still up to 108. The whole abdomen was sore and painful. Strange to say, the patient remem-

bered nothing of her condition the night before, and did not even recall the presence of the doctor. This seems to show that antifebrin produces an effect on the nerves similar to an hypnotic state, in which the patient can be made to answer questions and obey commands without having any self-consciousness.

"The next day the patient showed a marked loss of appetite; the face was flushed, and she complained of a severe headache. The symptoms of the poisoning had disappeared." It is unfortunate that the quantity of the drug taken was not more clearly indicated.

A NEW METHOD OF TREATING THE VOMITING OF PREGNANCY.

Notes of three cases published by DR. WILLIAM DUNCAN in the *Lancet* for October 15, 1887, would appear to indicate a method which in many cases will appear to produce the most marked success in overcoming the vomiting of pregnancy. Dr. Duncan found in a number of cases which he examined that the vomiting of pregnancy was accompanied by some affection of the uterus and tenderness about the cervix and vagina. He employed a fifteen per cent. solution of cocaine in such cases, painting it freely on the vaginal roof and cervix, and in some instances inserting a probe covered with cotton-wool and soaked in the solution into the cervical canal. It would appear that the *modus operandi* of the cocaine would be to remove the morbidly hyperæsthetic condition of that portion of the uterus above the internal os, which is supposed to exist in these cases. Dr. Duncan claims that to obtain the full effect of the cocaine it must be applied to the cervical canal, and herein lies the danger, for a careless or unskilful application might readily produce abortion. Dr. Duncan, however, states that he has made a number of such applications to the cervical canal during gestation without terminating the pregnancy in a single instance.

ACETPHENETIDIN AS AN ANTIPYRETIC.

Acetphenetidin is a combination of acetyl with phenetidin, and is a base of analogous composition with acetanilide (antifebrin).

DR. G. KOBLER, in the *Wiener Med. Wochenschrift*, speaks of it as an antipyretic. He says that although a healthy man will not be affected by doses of 0.5 to 0.7 gramme ($7\frac{1}{2}$ to $10\frac{1}{2}$ grs.), yet in fever patients 0.3 to 0.4

gramme will be found to reduce the temperature to a marked degree. Dr. Kobler cites fifty fever cases in which the drug was successfully used, among which were cases of tuberculosis pulmonalis, pneumonia crouposa, typhus abdominalis, sepsis puerperalis, pleuritis, and meningitis cerebro-spinalis. He states that in adults doses of 0.6 to 0.7 gramme, and in children 0.2 to 0.3, proved sufficient.

The drug begins to act in about four hours, and will keep the temperature down from two to three hours at the longest; then the temperature will slowly rise about 0.2° C. The influence of the drug seems to be lost in about eight hours.

According to Dr. Kobler there are no disagreeable symptoms accompanying the use of acetphenetidin, neither is the rise of temperature accompanied by sweating or the fall by chills. Cyanosis and collapse were not observed. Out of ten cases of pneumonia treated with the drug, six terminated fatally on the fifth and sixth days. In one case of pneumonia in a patient also affected with Bright's disease acetphenetidin was given in doses of 0.7 to 1.6 grammes without any signs of intoxication.

The drug seemed to have no injurious effect on the diseased kidneys. In the beginning of the disease there had been a good deal of blood in the urine, which, however, grew less under the use of acetphenetidin.

ADONIS ÆSTIVALIS.

This plant has been examined by Italian doctors as to its therapeutic value, and Albertoni reports in its favor. His experiments were made on animals and sick and healthy people. In cases of insufficiency of heart-action, with feeble, irregular, rapid pulse, diminished arterial pressure, dyspnoea, and diminished excretion of urine, the administration of the plant in substance produced, in a few days, the return of normal pulse, increase of the pressure of the blood, and disappearance of the respiratory oppression. The quantity of urine increased from eight hundred to three thousand cubic centimetres in a day. These good results were not obtained in cases in which the organs susceptible to the influence of adonis, such as the kidney epithelium, muscular fibre, and the nerve apparatus of the heart had already retrograded to too great an extent. The dose is 4 to 8 grains a day, given in substance or infusion. The effects manifest themselves about the third day.—*Pharmaceutical Record*, October 15, 1887.

GASEOUS RECTAL INJECTIONS AND THE GLYCOGENIC FUNCTION OF THE LIVER.

MM. ARNOZAN and FERRÉ, of Bordeaux, communicated to the Toulouse Congress an interesting observation they had made with reference to gaseous rectal injections tending to show that sulphuretted hydrogen introduced into the animal economy in this manner arrests the glycogenic function of the liver. Three rabbits which had been subjected to these injections died, two of them in a short time, the third after a rapid and progressive emaciation. In all three the liver-tissue was found to contain no sugar whatever.—*Lancet*, October 8, 1887.

HÆMATEMESIS.

The stomach of a patient suffering with hæmatemesis is always extremely sensitive. A mere drop of water or medicine, or a drop of blood from the wound, will cause burning and symptoms of vomiting. It is, therefore, very difficult to give any medicine to the patient. Their spirits are also always depressed, as even talking and the swallowing of saliva will irritate the stomach.

DR. GEYZA DULÁCSKA gives an account of ten severe cases in the *Pester Med.-Chir. Presse*:

CASE I.—Varix of the œsophagus; hæmatemesis; death.

CASE II.—Ulcer of the stomach during pregnancy; vomiting of blood after birth; recovery.

CASE III.—Ulcer of the stomach; vomiting of blood; recovery.

CASE IV.—Hæmatemesis during hypertrophy of liver.

CASE V.—Adenoid degeneration of the liver; recovery after long and frequently recurring hæmatemesis.

CASE VI.—Man, aged 62, with amyloid degeneration of liver and spleen, who, when lifting a heavy weight, suddenly became ill, and began to vomit blood.

CASES VIII., IX., and X.—Vomiting of blood in connection with heart-affections.

Dr. Dulácska says that in internal hemorrhages astringents are useless, and the only hope of recovery lies in coagulation or the stopping up of the bleeding vessels.

In rupture of the spleen rapid coagulation often checks the hemorrhage, and makes recovery a possibility. Indeed, even in the rupture of abdominal aneurism, coagulation

will sometimes keep life a whole week, when immediate death was looked for.

The arrest of the hemorrhage depends on the formation of a thrombus.

The doctor's remedies are rest, ice, and ergotin. The first day the patient should neither eat nor drink, so as to give the stomach perfect rest. On the second day, iced milk in small quantities may be given. Absolute rest must be had, as any movement is liable to cause irritation of the stomach. The patient must not be allowed to speak. Small pieces of ice may be put in the mouth, but the ice-water must not be swallowed. Washing out of the mouth with ice-water will quench thirst. On the fourth or fifth day meat may be given. Ice-bags may be placed over the stomach, but they are not of any great value, and frequently the patient cannot bear their weight.

By means of ergotin the pulse may be reduced 10 to 15 to 36 beats, and the smaller arteries contract themselves, and the frequency of the respirations will be less. It must not be given by the mouth, but as an injection in a ten to twenty per cent. solution.

THE URINE IN TABES DORSALIS.

The following facts are set forth by MM. LIVON and ALEZAIS as the result of a series of researches on the urine of patients affected with an apyrexial disease of the cord,—namely, tabes dorsalis: A tendency to diminution of the urea eliminated in the twenty-four hours; a diminution in the total daily discharge of phosphoric acid, with a tendency to proportional augmentation of the discharge of earthy phosphates; a great variation in the elimination of chlorine, with a bias in favor of hyperchloruria. Intravenous injections of tabetic urines appear to be sufficiently toxic in their action, since it has been found that from twelve to twenty-four cubic centimetres of urine per kilogramme of body weight of animals was sufficient to kill dogs.—*Lancet*, October 15, 1887.

SCOPOLIA ALKALOIDS.

It will be remembered that some time since Professor Eykman announced that he had separated from Japanese belladonna-root (*Scopolia japonica*) an alkaloid resembling atropine, which he named "scopoleine," and under that designation a brown syrup has since been supplied in commerce as a mydriatic alkaloid.

According to PROFESSOR SCHMIDT, of Marburg, however, the scopolia-root contains no new alkaloid; but atropine, hyoscyamine, and hyoscyne occur in the root in varying proportions, so as to suggest that the conditions of growth and the time of collection essentially influence the relative quantities of the alkaloids. Professor Schmidt is even inclined to think that under certain conditions these three alkaloids may be converted one into another in the plant, and in support of this he recalls Professor Ladenburg's statement that when tropine and tropic acid, derived from the decomposition of hyoscyamine, are recombined, the product is not the original alkaloid, but its isomer atropine. Hyoscyamine was also found in the root of a cultivated species, *Scopolia Hartnackiana*, and both roots yielded "scopoletin," a fluorescent compound, identical with the methyl esculetin occurring in belladonna-root. Professor Schmidt also disputes the basic character of the substance hitherto known as "rotoine," which he thinks is more likely a compound of alkali, with a fatty acid very rich in carbon,—a soap, in fact,—and ought, therefore, to be struck off from the list of alkaloids.—*Pharmaceutical Journal and Transactions*, October 1, 1887.

IODOFORM AS AN ANTISEPTIC AND ANTIPARASITIC.

The following abstracts are taken from the *Centralblatt für Chirurgie*, September 10. The "iodoform question" is one of great interest to all surgeons, and should be definitely settled. We hope that these rather contradictory views will stimulate experimenters on this side of the water, and that we shall be able to publish the result of their observations.

KÖNIG, in the *Therapeutische Monatshefte* for April, 1887, gives an interesting account of his experiments. His conclusions are based on years of careful observations, and he considers iodoform of great value as a dressing for wounds. He states that it has little or no bacteria-killing properties, and also that it is not a specific against tuberculosis, as it does not hinder the formation of tubercle-bacillus. The only effect it has on a healthy wound is to dry it up more or less and to promote healing, and it also renders the surface of the wound proof against the further growth of bacteria. Other remedies can ably take the place of iodoform.

C. BING also agrees with König as to the "drying properties" of iodoform. He experi-

mented with iodoform dissolved in the oil of almonds on the mesenterium of a frog, and found that it checked to a great degree the extravasation of the colorless blood-corpuscles.

According to his views, the drops of fat on the surface of the wound dissolve the iodoform sufficiently to cause it to act as "iodoformized oil." It is the iodine in vapor form that checks the exit of the colorless corpuscles from the vessels (*Therapeutische Monatshefte*, May, 1887).

G. DE RUYTER, in the *Archiv für Klin. Chirurgie*, vol. xxxv., Part 1, gives the results of a long series of experiments, partly conducted in the Hygienic Institute and partly in the Imperial University clinics of Berlin.

He speaks of iodoform as "a protective filter which guards against the approach of bacteria." On surfaces where they already exist the iodoform will cause their formation to be more gradual.

The bacillus of green pus and the micrococcus prodigiosus remain unchanged by iodoform.

In contradiction to this, however, it has been shown that the drug does in a measure check their formation and may sometimes render them harmless.

Ruyter says that of still greater importance are the *solutions* of iodoform. A solution of ether (two parts), alcohol (eight parts), and iodoform (one part) is a superb antiseptic. In the above solution, after standing for six weeks, the author found one per cent. of free iodine. This solution not only checks the formation, but also kills the bacteria.

In healthy wounds which had been disinfected with the ether-alcoholic solution of the drug, the bacteria when introduced into the wound died in one and a half minutes; in wounds where they already existed the solution acted slower, as the bacteria lived for two to three days. His results prove that this solution of iodoform has a right to be classed among the leading disinfectants.

DR. H. SATTLER (Prague) writes of a long list of experiments with iodoform and iodol (*Fortschritte der Medicin*, vol. v., 1887).

The friends of iodoform cannot be grateful enough for the publication of his results. He confidently states that the question is not whether iodoform is an antiseptic; that has been proved beyond all doubt. The only question is as to how it acts on the tissues and secretions and micro-organisms. His results are similar to De Ruyter's, and he further states that only those micro-organisms

which come in direct contact with the drug are affected by it ; those at a distance remaining unaffected. This accounts for the contradictory results of various experimenters.

The author concludes by saying that, on account of its sure effect and non-irritant properties, iodoform occupies a place among antiseptics which cannot be taken by any other drug.

The same applies to iodol. It is as active an antiseptic as iodoform. He prefers powdered iodoform to iodol on wounds, as the latter slightly irritates them.

The author considers iodol-vaseline of far greater value than iodoform-vaseline, although the former may cause slight burning to the sensitive parts.

BAUMGARTEN, in a lecture delivered before the Medical Society of Königsberg, denies the antiparasitic properties of iodoform (*Berlin. Klin. Wochenschrift*, No. 20, 1887).

Having injected some tubercle-bacilli into the trachea, a tubercular knot formed where the injection had been made, although the canula had been inserted through a thick and wide plaster of iodoform which covered the spot. When, however, the canula was inserted and withdrawn through a wad of cotton which had been soaked in a one per cent. solution of corrosive sublimate, no infection of the puncture took place.

Again, small flakes containing the bacilli were well mixed with ten to forty times their quantity of iodoform. This mixture was then introduced into the subcutaneous cellular tissue of rabbits and guinea-pigs. In every case the micro-organisms grew quickly in connection with the iodoform.

In the same manner Kunze made a series of experiments, all of which resulted unfavorably for iodoform.

THORKILD ROVSING (Copenhagen), in the *Fortschritte der Medicin*, vol. v., 1887, has endeavored to answer the question, Has iodoform any anti-tuberculous properties?

He draws the following conclusions from his experiments on the eyes of rabbits with "pure tubercle" and "tubercle treated with iodoform":

1. Iodoform has no effect on the life of the bacillus, whether in the body or in living tissue or under the influence of light.

2. Iodoform acts as an irritant on the tissues, and thus makes the surface more favorable for the growth of the bacillus.

The experiments of Rovsing were not very extensive, and so—after reading the results of other authorities, such as De Ruyter—it

would be well not to draw any too positive conclusions from the above.

P. BRUNS and WANWERK (in the *Mittheilungen aus der Chirurg. Klin. zu Tübingen*, vol. iii., Part I., 1887) went through a series of experiments with iodoform on abscesses. They worked with the microtome and microscope, and their results are highly gratifying. They describe the action of iodoform histologically as follows:

"The spindle-shaped cells grow rapidly, and a healthy, highly vascular, granulating tissue forms, which gradually lifts off the tuberculosed and necrosed parts. After the disappearance of the bacilli the vessels become obliterated, and the granulations either disappear or else are changed into connective tissue with the spindle-cells; exudation ceases; the contents of the abscess are absorbed, and the walls shrink together and cicatrize.

A. LÜBBERT (Dresden), in the *Fortschritte der Medicin*, vol. v., 1887, writes of forty-three experiments on animals, and comes to the conclusion that iodoform has no effect on the growth of the staphylococcus.

If iodoform is being used a second infection is more difficult, on account of the drying properties of the drug.

We need go no further into Lübbert's experiments, except to say that his results are in exact opposition to those of Sattler.

A POWERFUL DEODORIZER FOR IODOFORM.

Oil of turpentine is a powerful deodorizer for iodoform. A little rubbed on the hands will completely remove the smell from them. The hands should be afterwards washed in soap and water. In the same manner spoons and any utensil may be freed from the smell of iodoform.—*Le Progrès*, Geneva, August 20, 1887.

A CASE OF IODOL-POISONING.

PALLIN writes of a case of iodol-poisoning in the *Hygeia* (Swedish) for May, 1887:

The patient, a man aged 20, was suffering from necrosis of the clavicle. In the evening of the same day the patient became dizzy and violent, and tried to tear off the bandage. The next day the temperature was up to 39° C., and the pulse 136, small and irregular; vomiting and apathy. Albumen and a small quantity of iodine was traced in the urine. Although the dressing was at once changed,

the iodol washed away and bismuth substituted, the symptoms of poisoning remained for four days, and iodine could be traced in the urine for two weeks.—C. Lanenstein, in the *Centralblatt für Chirurgie*.

DIOXYNAPHTHALENE.

The search for new remedies among the carbon compounds does not at present show any sign of relaxation, and one of the latest to be credited with useful therapeutic properties is dioxynaphthalene, $C_{10}H_6(OH)_2$. There are at least six compounds known that have the composition of dioxynaphthalene, or, as it is sometimes written, dihydroxynaphthalene, but the melting-point mentioned ($186^\circ C.$) is that of one prepared by fusing naphthalene disulphonic acid with potassic hydrate. According to DR. LÉPINE (*Archives de Pharm.*, September 5, p. 403), this compound, administered to asthenic persons in 25-centigramme doses, with a maximum daily dose of 1 gramme, has a remarkable effect in imparting energy, though without augmenting reflex action or increasing muscular power. Large quantities, however, appeared sometimes to produce weakening effects, and in two cases cyanosis followed the administration of one gramme. As the hydroxyl group has been credited with the property of augmenting the energy of a radical with which it may combine, and since the formula of dioxynaphthalene differs from naphthol ($C_{10}H_7HO$) in containing another HO group, Dr. Lépine was induced to experiment as to whether there might be any analogy in the physiological action of the compounds. His results were affirmative, and Dr. Lépine says that β -naphthol is capable of producing the same asthenic effects as dioxynaphthalene, but the dose required (2 or 3 grammes) causes irritation to the digestive and other organs.—*Pharmaceutical Journal and Transactions*, October 1, 1887.

THE USES OF NITRO-GLYCERIN.

The value of nitro-glycerin in medicine is now greatly appreciated. It is, however, important that we should be thoroughly acquainted with its properties. Its action in dilating the arteries is of great value, since it not only affects the large and also smaller arteries, but also the capillaries. We might regard its actions in a twofold light: first, it enlarges the arteries which have been con-

tracted, and so transfuses the blood into these almost bloodless vessels; second, in doing so it relieves those vessels which have been surcharged with blood, and thus its action might be compared with that of bleeding.

Nitro-glycerin is useful in angina pectoris, neuralgias, and the like; also in sea-sickness, fainting fits, palpitation, etc. As these ailments all occur in paroxysms, the object in using the drug is to give immediate relief. Its continued use will be found of service in Bright's disease, fatty degeneration of the heart, etc., and in all similar ailments where symptoms of an irregular distribution of the blood are apparent.

DR. TRUSSEWITSCH, in an article on the subject in the *Centralblatt für die gesammte Therapie*, says that the best way to judge the size of the proper dose is by carefully watching its effect on the pulse. He states that the more contracted the radial artery is the sooner it will dilate under the drug, and the accompanying effects will be good; the fuller the pulse the less effect nitro-glycerin seems to have, and the weaker and more yielding the pulse the easier it will be to cause an undue and general effect on the whole organism.

Therefore, in cases of the first-mentioned kind, normal doses (that is, not more than 1 drop of a one per cent. solution) will be all that is needed. In the second kind one may give even as much as 2 drops with safety, not however, without first having tried the effect of the normal dose. In cases of the third kind only $\frac{1}{4}$ or $\frac{1}{2}$ drop may be given at first, so as to avert the disagreeable symptoms which might be caused by a "hyperdosis."

These rules, of course, apply only to those who have not been using the drug habitually, and in weak, nervous, poor-blooded, and timid patients it is always advisable to begin with very small doses.

Dr. Trussewitsch further says that organic heart-trouble does not by any means contraindicate its use, he having used it with good results in angina pectoris, which was complicated by valvular trouble and dilatation of the aorta; also in cases where the heart was enlarged.

The greatest caution, however, must be taken when giving the drug where there is general atheromatosis of the arteries.

Under no circumstances should the dose ever be increased above 2 drops of the one per cent. solution, and even in angina pectoris the increase of dose must be very gradual. If in long-standing cases one begins to find even the increased dose losing its effect, it

will be well to discontinue its use for two weeks or so, at the end of which time the normal dose will be found to have its original effect again. This peculiarity of nitro-glycerin is of great importance, since, even when its use becomes habitual, any undue increase of dose will be found unnecessary.

The best methods for administering the drug are either to drop the solution on the tongue by means of a pipette, or else to have it put up in small tablets of chocolate. The practice of giving it in water is not advised, as it gives bad therapeutic results.

The author also finds that it combines well with other remedies. In combination with digitalis it acts well on patients with weak and irregular heart-action, with cocaine or morphine for neuralgia, and sometimes even with nitrite of amyl in angina pectoris.

The drug should be perfectly pure, as when it is poorly prepared it is utterly worthless.

THE TREATMENT OF DIPHTHERIA.

DR. AD. DUMAS, in the *Bulletin général de Therap.*, says that there is no remedy for fully-developed diphtheria, and therefore it is necessary to check the disease in its infancy.

When healthy children are living near others suffering from diphtheria, they are naturally in danger of contracting it themselves. Therefore the greatest watchfulness is necessary, so as to be able to cope with the enemy at his first appearance.

Dr. Dumas states that he considers it advisable to treat a child antiseptically even before there is any appearance of the disease.

He advises a one per cent. solution of kalium iodide with 8 drops of tincture of iodine to be given daily; also in the night, disturbing as little as possible the sleep of the child.

This treatment should be continued for about a week.

True, the writer's experience is limited, he having based his conclusions as to the value of this preventive upon the observation of only nine cases.

PULSATILLA.

As pulsatilla contains a sharp, active principle which is lost when dried, it is necessary to use only fresh roots in preparing the drug.

The roots also are more active than the leaves.

M. S. VIGIER says that the only useful preparation is the so-called "alcoholative" (1 to 1000 alcohol, 90°). The nauseous taste and smell of the above are greatly reduced by using the following formula:

R Syr. fol. naphæ, 95 grms.;
Alcoh. rad. anem. rec., 5. M.
S.—1 to 3 teaspoonfuls daily in water.

The distillate of anemonin water or any solution of anemonin is very sharp and active. After some time, however, it loses its sharpness and disagreeable odor, and precipitates white leaf-like crystals of anemonin, which are tasteless and odorless.

The formula $C_{16}H_{12}O_6$ has taken up an equivalent of O, and has changed into anemononic acid.

Vigier says it should not be considered poisonous, himself having frequently taken 1 gm. (15 grs.) without effect.

He gives the following formulæ as the best in using anemonin:

R Anemonin, .01;
Sacchar., .09.

For 1 powder, to be taken two to four times daily.

Or

R Anemonin, .01;
Pulv. liquid., .02;
Syrup., q. s.

For 1 pill, to be taken two to four times daily.

The above formulas have also strong anti-catarrhal properties.

ANTIPYRIN AS A NERVINE.

The value of antipyrin in nervous diseases is beginning to be widely acknowledged. Demme, in many experiments upon animals, saw its marked effect both on the muscular and vasomotor nerve-centres. Further researches of other practitioners show various results. Thus, F. Müller (*Centrab. für Klin. Med.*), when using it as an antipyretic, observed sleepiness and incontinence of urine to be caused by it; May (*Deutsche Med. Wochenschrift*) observed vomiting, sweating, and numbness; Kaatzer (*Deutsche Med. Wochenschrift*), exanthema and sleepiness; and Steinacker also speaks of its sleep-producing properties. Ungar gave antipyrin with good results to a patient suffering with hemicrania in doses of 1 gramme (15 grs.), although he said its actions were not always certain. Many other

writers speak of its good effects in nervous headaches. Robinson advises its use in doses of about 1.32 gramme (20 grs.) in Vichy water, and this dose to be repeated in two hours if the pain has not increased.

DR. OTTO SEIFERT, in the *Centralblatt für die Klinische Medizin*, says that his observations with antipyrin in hemicrania were not very favorable. He cites two cases. First, one of a woman, aged 24, who was subject to frequent and severe attacks. These he completely checked three times with 1 gramme (15 grs.) doses of antipyrin, but at the fourth time gastric irritation became apparent, and he was forced to discontinue its use. The second case was that of a woman, aged 21, who suffered from attacks of hemicrania, which came on every two or three weeks. All other remedies, such as quinine, caffeine, etc., had been tried without avail. After a single dose of antipyrin disagreeable symptoms at once began to manifest themselves,—great pain in all the limbs, dizziness, headache, etc.,—so that, indeed, the effects of the drug were more painful than the disease itself. Antifebrin, on the other hand, was given with very good results and without any disagreeable accompanying symptoms.

It would therefore appear that, whether or not fever exists, antipyrin is oftener accompanied with unpleasant symptoms than antifebrin. It is, however, especially noticeable in fever-patients.

Antipyrin has been prescribed in neuralgia of the trigeminus by Drs. G. Sée and Mendel. The results of Dr. Seifert here were more satisfactory than in hemicrania. In three cases of supraorbital neuralgia, doses of 1 gramme (15 grs.) caused complete disappearance of pain in an hour, and its continued use for several days resulted in recovery. There were no disagreeable symptoms accompanying its use.

Dr. Seifert also speaks of its efficiency in allaying the pain of tumors of the brain and several other cerebral affections; also in heart-troubles, such as stenocardia, aneurisms, angina pectoris, etc., although in such cases antifebrin can always ably take its place. Mendel also speaks of its value in epilepsy and in several painful affections of hysterical patients.

Whether antifebrin, on account of its cheapness, and the lesser number of its accompanying symptoms, will take the place of antipyrin in nervous diseases, will soon be settled, as at present the subject is being largely discussed in all the leading medical journals.

ARBUTIN.

Arbutin is a specific body, which is found in the residue of the *fol. uva. ursi*. It is a glucoside, and is contained in the leaves in connection with gallic and other acids. When heated with dilute sulphuric acid it is split into the glucoside, and sugar on the one hand and hydrochinon and methyl hydrochinon on the other hand. Both of the aromatic products are very active, signs of poisoning appearing in animals after doses of 1 gramme (15 grs.) of hydrochinon.

When introduced into the stomach, arbutin is divided into the minutest particles, but is found unchanged and almost in its entire quantity in the urine. A pupil of Kunkel took 9 grammes of arbutin without any unpleasant effect, but the drug was easily traced in the urine. It seems that the drug is almost completely thrown off with the urine.

The percentage of arbutin in the dry leaf is about five per cent.—J. KUNKEL, "Ueber das Arbutin," *Centralb. für die Klin. Med.*

DAPHNANDRA REPANDULA.

A Queensland plant recently examined by DR. BANCROFT is *Daphnandra repandula*. The bark of the tree has a transient bitter taste, and when first removed from the tree it has a yellow color on the inner surface, which changes to metallic black on exposure to the air, but becomes yellow again when dry. Infusions of the bark are of a yellow color, and remain free from microscopic organisms when kept. The extract of the bark does not appear to contain either gum or resin, but is rich in alkaloids. The extract is very poisonous, 1 grain being a fatal dose for a frog, and 10 for warm-blooded animals. The alkaloids contained in the bark are colorless when pure and crystalline. The active one is easily separated from the others, being soluble in water. Its poisonous action is chiefly due to its action on the heart. To some extent it is antagonistic to strychnine. The poison powerfully affects fish, mollusks, and infusoria. When applied topically to voluntary or involuntary muscles it paralyzes them rapidly. Dr. Bancroft has remarked that it also retards the development of septic organisms and that it will deodorize putrid meat. It checks the growth of yeast and kills some water-plants. Another species, *D. micrantha*, which is a shrub and also grows near Brisbane, possesses a similarly active principle.—*Pharm. Journ. and Trans.*, October 1, 1887.

THE TREATMENT OF CARBUNCLE BY INSERTING BARS OF CAUSTIC CHLORIDE OF ZINC.

At the meeting of the Société de Médecine of Paris, on June 11, M. POLAILLON (*London Med. Record*, October 15, 1887) made an interesting communication on the treatment of carbuncle by the insertion of bars of caustic chloride of zinc. M. Polaillon bases his treatment on the fact that carbuncle is caused by a microbe, and that incision by a bistoury is sometimes dangerous, as liable to open out numerous roads to inoculation and septicæmia. When the inflammation does not give way to simple treatment by baths and emollients, it is generally necessary to have recourse to the bistoury, or, better still, the thermo-cautery, which presents less danger; but M. Polaillon prefers employing caustics, which entirely destroy the germs in the purulent focus. For that purpose he chooses Canquoin paste, chloride of zinc, in the form of sticks or bars, hardened by desiccation in a furnace. When the carbuncle is suppurating, and when the skin is perforated at several points, he introduces through these apertures bars of caustic, thrusting them easily down into the focus, so as to fill it with these bars. At the end of a few hours the focus forms one solid mass, separated from the healthy tissue by a zone of cauterized tissue; and in a few days the eschar is eliminated, leaving in its place a granulating surface, which rapidly heals. When the focus is beginning to form, and shows itself only by some white spots on the surface of the skin, he makes a sufficient number of openings with the bistoury or the thermo-cauterizer to introduce the bars of caustic, and proceeds as above. When the carbuncle is only in its first stage, and there is no suppuration and but little fever, M. Polaillon simply applies emollients until the affection has progressed sufficiently for him to apply the caustic bars. But if the carbuncle is accompanied by intense febrile symptoms, if it is voluminous, he does not hesitate to treat it at once with bars of Canquoin paste. In all cases he covers the surface of the carbuncle with a thick layer of compresses, soaked in a carbolic-acid solution, or, better still, with a solution of sublimate at one per one thousand, which he prefers. He applies a linseed-meal poultice, made with the solution of sublimate, and thus obtains the antiseptic effect of the sublimate and the emollient effect of the poultice. This treatment is rather painful for two or three hours, but has the advantage of at once transforming a serious infectious dis-

ease into a simple wound. The results obtained by M. Polaillon with this treatment of carbuncle were excellent. Out of forty-eight cases brought to him, he had forty-seven cures and one death. This was a man of 48 years of age, highly glycosuric, and who had already been very irregularly treated at home during a month. He had an immense carbuncle in the back, and notwithstanding every care and energetic antiseptic treatment, diffuse inflammation carried him off one week after entering the hospital. The average duration of this treatment is twenty-one days only.

TERPINHYDRATE AND TERPINOL.

RABOW (*Therapeutische Monatshefte*, August, 1887) has not yet been able to form a definite opinion on the value of terpin and terpinol as remedial agents, but he gives a good account of these drugs and a *résumé* of the latest experience as to their utility.

If ol. terebinth. and water are left to stand for some time, crystalline needles occasionally form on the walls of the vessel. They consist of terpin, or, more correctly, of terpin-dihydrate, $C_{10}H_{16} \cdot 2H_2O + H_2O$. A monohydrate, $C_{10}H_{16}H_2O$, is obtained from French turpentine oil; this is a colorless oily fluid.

According to B. Fischer, *Neuere Arzneimittel*, p. 137, terpinhydrate is prepared in the following manner: A mixture of four parts rectified oil of turpentine, three parts alcohol (80° C.), and one part nitric acid is left to stand for a few days in a large flat porcelain dish; the crystals collected in the fluid are then taken out and left to dry; they are then pressed between filter-paper and recrystallized out of a ninety-five per cent. solution of alcohol.

Terpinhydrate forms rather large rhombic crystals; they are colorless and odorless, and have a faintly-aromatic taste. It is with difficulty soluble in cold water and turpentine oil, and more easily in hot water, alcohol, ether, and carburetted hydrogen.

The advantageous results obtained from turpentine in lung- and kidney-affections, by Lépine, Sée, Masius, and Ferreira, have already been recorded in the *Medical Chronicle*, October, 1885, and January and July, 1887. Rabow (as quoted by the *Medical Chronicle* for October, 1887) gives the following formulæ for the administration of the drug,

which may be prescribed either in pills or solution :

R Terpini hydratis, gr. xlv ;
Sacch. alb.,
Mucil. gum arab., q. s. M.
F. pil. No. 30.
S.—1 pill three times daily.

R Terpin. hydr., gr. cl ;
Spir. vin., ℥v ;
Aq. destill., ℥iii. M.
S.—1 tablespoonful t. d.

R Terpin. hydr., ℥ii ;
Glycerin (at 30° C.),
Sp. vin. (at 95° C.),
Syr. simpl., aa ℥iiss.

Terpinol is a colorless oily fluid, which is produced when terpin is boiled with diluted mineral acids. It is insoluble in water. It is a stimulant to the bronchial mucous membrane, the secretion of which it renders less viscid. When taken internally it is excreted by the lungs. It does not disturb the stomach unless given in large and long-continued doses. It has been recommended as an expectorant in lung-diseases, and, according to Morra, is more effectual than terpin. It has no visible effect on the kidneys and the nervous system. It may be given in pills or capsules, or it may be injected into the rectum.

Dr. Lazarus, of Berlin, considers pills the best form of administration. 20 to 30 grains can be given daily in this form without discomfort. He believes that only in such full doses can the therapeutic influence of the drug be relied upon. It is useful, he says, when the bronchial mucous membrane is much irritated and the secretion is small and tenacious. This condition is not infrequent in chronic catarrh, in emphysematous and phthisical patients. The secretion is increased, and becomes more fluid ; the irritation correspondingly diminished. In a week or a fortnight the catarrhal symptoms usually disappear.

Haussmann, of Merau, does not report quite so favorably, but finds that the patients bear terpin much better than turpentine. The dose is from 2 to 15 minims. Whether terpinol and terpin are as useful in diphtheria and whooping-cough as turpentine oil, Rabow says, has not yet been ascertained. The terpin is to be dissolved in the warm glycerin. The mixture of spirit and simple syrup is to be added to this solution and shaken. Each tablespoonful contains seven and a half grains of terpin.

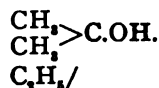

PHARMACEUTICAL NOTES ON SOME SYNTHE-
TICAL COMPOUNDS RECENTLY
INTRODUCED INTO MEDICINE.

Although we have already laid before our readers abstracts of the more important papers appearing on the compounds noted below, it seems worth while to give again a summary in a condensed form of the more important characteristics of each of these new remedies, with special reference to their mode of administration. In accomplishing this we make use of the paper read by MR. H. HELLING before the British Pharmaceutical Conference, reported in the *Pharmaceutical Journal and Transactions* for September 24, 1887.

Acetphenetidin, paracetphenetidin, $\text{NH}(\text{CO CH}_3)\text{C}_6\text{H}_4\text{OC}_2\text{H}_5$.—This antipyretic has only been in use for a short time, but the results hitherto obtained with it are described as excellent. Hinsberg and Kast have shown that a dose of 3 to 8 grains is able to reduce the temperature of the human body by 3.6° F., and the experiments carried out in the clinic of Professor von Bamberger, of Vienna, have only tended to confirm the favorable accounts of the discoverers. It appears to be perfectly devoid of secondary effects and fully able to bear comparison with all other febrifuges.

It is a grayish-white crystalline powder, without smell, producing a slightly pungent after-taste ; it is practically insoluble in water, but dissolves readily in alcohol. The melting-point is at 275° F. It is advantageously prescribed in the form of powders containing the above-mentioned dose, since from its tastelessness it is readily taken by patients.

Amylene hydrate, tertiary amylic alcohol, dimethyl ethylcarbinol,

Only a few weeks ago this compound was recommended by Professor Jolly and Von Mehring as a soporific, in which class of remedies it appears to have taken a prominent place. Before applying it to patients numerous experiments on animals had been carefully carried out. A dose of one drachm is sufficient to produce sleep for six or eight hours. No unpleasant secondary effects are recorded.

The remedy is given in water (in which it is soluble in the proportion of 1 to 12), with a little juice of liquorice.

Amylene hydrate,
Liq. glycyrrhizæ, aa ℥i ;
Aq., ad ℥i.

S.—To be shaken before use.

It is also administered in capsules of gelatin.

It is a clear fluid, with an odor reminding one slightly of camphor; it is soluble also in alcohol. Specific gravity, 0.812 at 53.6° F.; boiling-point, at 216° F.

Antifebrin, acetanilide, phenylacetamide, C₈H₇NH.CH₃CO.—Since the first experiments with this valuable remedy, performed by Drs. Cahn and Hepp in Strasburg, antifebrin has been carefully studied by others, and with the same satisfactory results. It possesses the advantages over other remedies of this class of being low in price, and, moreover, the dose is small, 2 to 10 grains once, twice, or, at most, three times a day, sufficing to produce a considerable reduction of temperature in cases of typhoid fever, pneumonia, also in erysipelas and acute rheumatic gout. It is given in powders as well as in solution; for the latter mode of administration it will be found most advisable to dissolve it in brandy, subsequently adding a little water and syrup. The following formula is given as an example:

Antifebrin, ʒi;
Brandy, ʒivss.
Dissolve, and add
Distilled water,
Simple syrup, aa ʒvi.

One tablespoonful, to be taken as directed.

The remedy is thus rendered very pleasant to take, and the patients express no aversion to it.

A good preparation should be of pure white color, and form moderately large crystals, which are but very sparingly soluble in cold water, rather more readily in hot, and easily in alcohol. Antifebrin melts at 233.6°, and boils at 563°.

Antipyrin, oxydimethylchinizine, C₁₀H₇CH₃.N₂O.—Antipyrin may fairly be considered the most popular of modern antipyretics. The dose varies from 15 to 30 grains twice, three, or more times a day. For children, 3 to 12 grains will be found to be sufficient. It is of great value in all febrile diseases, reducing temperature very promptly. Of late it has also been applied in subcutaneous injection as a local anæsthetic. In some cases a bright pink rash, like nettle-rash, will suddenly appear during treatment; this is considered to be of no importance, as it causes no inconvenience, and soon disappears.

Antipyrin is readily soluble in water and alcohol; it possesses but little flavor, and that not unpleasant, and is, therefore, adapted

for administration in solution. It thus possesses great advantages over quinine, especially in treating children, who take it very readily if mixed with a little syrup. Thus:

Antipyrin, gr. lxxx;
Simple syrup, ʒi;
Water, add to ʒiv.

Two teaspoonfuls for a dose.

This mixture is almost free from bitterness, and children do not at all object to it.

It crystallizes in colorless laminæ, which melt at a temperature between 230° and 254.4° F.

Antithermin, phenylhydrazinlevulinic acid, CH₃C(C₆H₅N—NH)CH₂—CH₂COOH, has been recommended as a febrifuge, but, although it is now obtainable in the market, details are still wanting as to dose and effect. It forms large colorless crystals of a slightly bitter taste, which cause an unpleasant grating when ground between the teeth. It is insoluble in water, and but sparingly soluble in alcohol. The most suitable form for administering antithermin is the pilular.

Aseptol, acidum sozolicum, orthophenolsulphonic acid, C₆H₄OH.SO₃OH.—By aseptol we understand a thirty-three and one-third per cent. solution of orthophenolsulphonic acid. It is almost odorless, but faintly suggests carbolic acid, and is reported to possess the antiseptic properties of the latter and of salicylic acid, standing, as regards strength, midway between them. Its superiority lies in the possession of antiseptic with poisonous or irritating properties, so that it is especially adapted for abdominal surgery and for ophthalmological operations. Sozolic acid is readily soluble in water, alcohol, and glycerin. It is applied in a solution of three, five, or ten per cent., to which strength the stronger solution can be reduced by dilution with water.

Betol, salicylate of β-naphthol ether, C₈H₇OH.COO.C₁₀H₇.—This remedy is one of the very newest and analogous to salol. It is applicable, therefore, in all those cases in which the latter is found to be of use,—viz., rheumatism, cystitis, etc. The dose is given as 5 to 8 grains in some cases of intestinal catarrh. As it is not a phenol compound, betol possesses the advantage of being freer from detrimental properties than salol.

It forms small, white, resplendent crystals, is almost devoid of taste, and, being insoluble in water, is best dispensed as a powder or in compressed tablets, or in pills made up with liquorice-juice and powder, each contain-

ing two and one-half grains of betol. It is soluble in alcohols, as also in fatty oils, and is, therefore, well adapted for being worked up with butter of cacao into pencils for the treatment of gonorrhœa. These may be prepared by melting four parts of ol. theobromæ, and adding to the warm liquid one part of betol. This readily dissolves in the fat, and the mixture is allowed to partially cool, when it is poured into moulds. The finished product contains, of course, twenty per cent. of betol. The melting-point of betol is 203° .

Hypnone, acetophenone, $C_6H_5COCH_3$.—By means of 3- to 8-grain doses of this very powerful soporific a profounder sleep is produced than that caused by chloral hydrate. Hypnone possesses an agreeable aroma, somewhat resembling a mixture of oil of bitter almonds and neroli, but its action on the mucous membrane of the mouth is almost caustic. It is dispensed, therefore, in capsules of gelatin, each of which contains one grain of the remedy, combined with ten of almond oil, to prevent any risk of unpleasant effects.

It is a colorless fluid, sparingly soluble in water, more readily so in alcohol, of the specific gravity 1.032 at 59° F., the boiling-point being 410° F.

Methylal, dimethylether of methylene, $CH_3(O.CH_3)_2$.—Methylal is a soporific of very recent date. It is administered in doses of 20 to 25 grains in water, with a little syrup.

Thus :

Methylal, \mathfrak{z} i;
Syr. orange-flower, \mathfrak{z} ss;
Water, \mathfrak{z} i.

One tablespoonful for a dose.

It has been applied externally as a local anæsthetic dissolved in oil, or as an ointment, with lard as a base. Both forms are made to contain fifteen per cent. of methylal.

It is a colorless, ethereal fluid, which smells like a mixture of chloroform and acetic ether, and tastes pungent and aromatic; it is readily soluble in water as well as in alcohol; the specific gravity at 59° F. is 0.855; it boils at 107.6° .

Naphthalin, $C_{10}H_8$.—To most fungi naphthalin has been found to be a powerful poison, and has proved very valuable as an antiseptic, being applied in the same manner as iodoform. Professor Rossbach, of Jena, first administered it internally in cases of acute and chronic enteric catarrh, in typhoid fever, and acute gastro-intestinal catarrh. It has since been extensively applied, but not with absolutely uniform results. It is given as a pow-

der in doses of 2 to 8 grains, to which a drop of oil of bergamot is added to obliterate the peculiar smell of tar belonging to it, which make it otherwise impossible for some patients to take it. For example, the following formula may be adopted :

Naphthalin, gr. xxx;
Sacch. alb., gr. xxx;
Ol. bergam., gr. i.

Make a powder and divide into ten doses, one to be taken three times a day.

Naphthalin is a crystalline body, forming colorless, resplendent scales; it tastes pungent, is insoluble in water, but sparingly soluble in cold alcohol and fatty oil, but readily if these agents are heated. The solution in oil and the ointments should be made to contain ten per cent. of naphthalin, which must be added to the warm fatty matter. Melting-point, 176° F.; boiling-point, 424.4° .

Naphthol, β -naphthol, isonaphthol, $C_{10}H_7OH$.—As a substitute for tar preparations, naphthol has been applied to the skin with very good results, especially in psoriasis and other chronic affections. A two to five per cent. solution in alcohol is the usual form of application, but it can also be made up into ointment containing three to twenty-five per cent. Internal administration of this compound was attended with toxic effects, and has, therefore, been discontinued.

It crystallizes in resplendent scales, has an aromatic odor, is slightly soluble in hot water, readily so in alcohol and fatty oil. A very good ointment can be made by adding one part of naphthol to ten of melted lard, and well stirring. The substance dissolves without much difficulty, and forms a white, smooth product.

Naphthol melts at 253° , and boils at 546.8° .

It should not be confounded with naphthalin.

Salol, phenylether of salicylic acid, $C_6H_5OH.COOC_6H_5$.—This remedy appears to give the greatest promise of future importance, for, in the short time that it has been known, it has done very good service as a febrifuge and an antirheumatic, being administered in doses of 15 to 30 grains, two or three times a day; also as a gargle, \mathfrak{z} ii. Thus :

Salol, \mathfrak{z} ii;
Spirit. vin., \mathfrak{z} iv.

A teaspoonful to a glass of warm water for stomatitis and ulcerations of the mouth and pharynx.

A salol mouth-wash is also very much recommended, and may be prepared as follows :

Take salol, gr. xl ; dissolve in ℥iv of a suitable spirituous dentifrice liquid. Half a teaspoonful to be used in a glass of water, with which it forms a milky emulsion.

For chronic forms of diphtheria it is reported to have more powerful effect than solutions of chlorate of potassium or salicylic acid. It is also applied, worked up with butter of cacao into pencils, as an antiseptic. These are prepared in a similar manner to those of betol, before mentioned.

Salol is a white, crystalline powder, of a mild aromatic odor ; it is insoluble in water, but soluble in alcohol. The melting-point is 108° F.

Thallin, $C_8H_{10}N(OCH_3)_2$.—Thallin is employed either as a sulphate or tartrate. It is rapidly obtaining a recognized position in the materia medica, for it is a reliable and powerful antipyretic, applicable in all kinds of febrile conditions. 3 to 8 grains in pill are considered a suitable dose. It is also applied externally, especially lately, with great success for injections in cases of acute and chronic gonorrhœa, for which it is prescribed in aqueous solutions containing one drachm of thallin salt in ℥vi.

Salts of thallin are crystalline powders, not quite pure white in color, of a bitter and intensely aromatic taste, and of a peculiarly persistent odor, which is similar to that of cumarin ; they are readily soluble in water, but far less so in alcohol.

Urethan, ethyl of urethan, $CO(NH_2).OC_2H_5$.—As a mild hypnotic, urethan is very useful, being administered in doses of from 15 to 40 grains, either as a powder or in solution, with a little syrup as a corrective. Thus :

Urethan, ℥ii ;
Syr. simpl., ℥i ;
Aque, ℥iii.

Two teaspoonfuls for a dose.

It does not produce a comatose condition like chloral hydrate, but tends to induce a healthy natural sleep in cases where this is impeded by other causes.

It is a crystalline body, of a mild ethereal odor, tastes somewhat like saltpetre, is soluble in water and alcohol, and melts at about 120° F.

THE EMPLOYMENT OF ANTIPYRIN IN ACUTE RHEUMATISM.

DR. BERNHEIM publishes a paper with the above title (*London Medical Record*, October 15, 1887) in which he gives notes of thirty-

four cases, comprising nineteen of acute and subacute rheumatism, eleven of apyretic rheumatism, two of gonorrhœal rheumatism, and two of neuralgia. In each case the daily dose of antipyrin varied from 2 to 8 grammes (30 to 120 grains), the treatment ceasing as soon as the pain was relieved. The drug was given in a simple solution. No untoward or disagreeable symptoms were noticed beyond profuse perspiration, which occurred in sixteen out of the thirty-four cases. Nausea, followed or not by vomiting, was complained of in four cases, but when gastric discomfort was feared the drug was given preferably hypodermically or by injection. Of these thirty-four cases marked relief was afforded in twenty-eight ; in only six cases was the effect uncertain or incomplete. In examining the effect of the drug in the different forms of the disease, it was successful in eighteen out of nineteen cases of acute rheumatism ; in eleven cases of apyretic rheumatism only twice was its administration of doubtful value, and even in these some relief was afforded, although they were undoubtedly cases of chronic rheumatism. Its effect on gonorrhœal rheumatism was less marked, and it was not more successful in a case of sciatica and one of supra-orbital neuralgia. The conclusion is that antipyrin is particularly indicated in true rheumatism, whether febrile or apyretic. The relief of pain experienced in such cases is prompt : within twenty-four hours the pain, swelling, and tenderness of the joints were less, and the pain soon disappears altogether. Dr. Bernheim, however, denies that antipyrin causes the resolution of the local lesions. The fever at once falls, but the relief of pain is not necessarily associated with this, since the same effect follows its administration in the apyretic form of the disease. Out of twenty-seven cases in which the course of the malady could not be followed to its conclusion, in twelve it persisted more than a week after the treatment was begun, varying from eight to sixty-three days ; in fourteen its duration was less than a week, and in seven of these fourteen cases the symptoms disappeared after the administration of a single dose of the drug. On the whole, antipyrin cannot be credited with any specific action on the course of the disease, for it in no way prevents the visceral lesions except in so far as the risk of complication is avoided by the period of disease being shortened. It is probably simply a powerful muscular analgesic acting through the nervous system.

DELPHINIUM STAPHISAGRA.

DR. VINCENT GAUTHIER, in a treatise entitled "*Recherches Expérimentales sur le Delphinium Staphisagra et sur la Delphinine*," Naples, 1886 (*London Medical Record*, October 15, 1887), propounds his personal botanical, chemical, and pharmacological researches on the *Delphinium staphisagra*.

This plant, belonging to the tribe of the Helleboridæ of the natural order of the Ranunculidæ, had formerly been separated from the genus *Aconitum*, to which it has recently been reunited by Baillon and other botanists. There are three species of delphinium, or larkspur,—the *D. ajacis*, *D. consolida*, and the *D. staphisagra*, the last being exclusively the subject of the author's investigations. The fruit is formed of four capsules, containing four to five black seeds, known by the name of stavesacre seeds. It is indigenous to the south of France, Italy, Greece, Asia Minor, and the Canary Islands.

The seeds of the *Delphinium staphisagra* contain, according to the researches of Marzius and of Dragendorff (1877), four kinds of alkaloids: the delphinoidine, the delphinia or delphinine, the staphisagrine, and the delphisine.

The most important of these is the delphinine, which forms an amorphous yellowish powder of resinous appearance. The chemical formula is $C_{22}H_{33}NO_4$. It is insoluble in pure water, but dissolves in acidulated water, in alcohol, ether, and in chloroform.

Only the seeds, which contain the greatest amount of active principle, have been employed for therapeutical purposes. They have been known as a very old remedy in psoriasis and as a vermifuge, in the form of powders, decoctions, infusions, and ointments.

The best form of prescribing delphinine is in granules or pills. The maximal dose is 1 to 10 milligrammes ($\frac{1}{10}$ to $\frac{1}{10}$ of a grain) during twenty-four hours, Trousseau's and Pidoux's doses of 15 to 20 milligrammes ($\frac{1}{4}$ to $\frac{1}{2}$ of a grain) being by far too powerful. Externally it is employed in ointment of one to five parts in ten parts of vaseline.

Dr. Gauthier draws the following conclusions from his experiments on the physiological and toxicological effects of the delphinine.

It is a modifier of the nervous system. It acts on the bulbous portion of the medulla and on the sympathetic nerve.

1. As regards its action on the sensibility, delphinine produces first functional excitation, followed by gradual attenuation, diminution, and final complete but transient extinction

of sensibility. The analgesia may in some cases continue for twenty-four hours. The delphinine, in order to produce these effects, acts upon the central fibres of the nerves. The effects of delphinine on the sensibility constitute its most important physiological and its sole therapeutic indication. It is in this respect preferable to aconite, being, moreover, less poisonous.

2. A small physiological dose produces no effect on the motor nerves. A toxic dose, however, rapidly destroys the functions of these nerves.

3. Its effects on the locomotor system consist in inco-ordination and ataxy.

4. The contractibility of the muscular fibres persists until the death of the animal.

5. In acting on the heart and the circulation, delphinine first accelerates the cardiac movements and renders them arhythmic. This is followed by a period of calm, characterized by rhythmic and regular contractions of greater force. Finally, the heart stops during the diastole. These effects are the consequences of the action of the delphinine on the bulbous portion of the pneumogastric nerves.

The alteration of the vascular tension of the blood consists in a transient increase, followed by a more or less marked abatement. The temperature is strictly proportionate to the modification of the tension.

6. Delphinine likewise influences the respiratory functions, causing typical irregularity of the respiratory movements, owing principally to the spasmodic condition of the respiratory muscles (the abdominal and intercostal muscles, and the diaphragm). In consequence of the arhythmic respiration, hypercarbonization of the blood takes place. When the tetanic spasm reaches its maximum the pulmonary movements cease, and the animal dies of asphyxia.

Death is brought on by the cessation of the respiration, and not by that of the action of the heart.

7. The effects of delphinine on the digestive organs are vomiting and diarrhœa.

8. The pupils are affected by means of the cilio-spinal centres; myosis is followed by mydriasis. The dilatation of the pupils may take place even after most minute doses of the alkaloid.

9. Delphinine is eliminated by increase of the secretions of the saliva, bile, urine, and of the intestinal secretions.

The treatment of poisoning by delphinine is guided by our knowledge of the mechanism

of the death from this alkaloid, which takes place by cessation of the respiration. Artificial respiration, therefore, must be at once resorted to in order to gain time for the elimination of the poison. There exists only a partial antagonism between delphinia and other alkaloids, with strychnia with relation to the sensibility, with atropia as regards the cardiac arrhythm. But neither strychnia nor atropia will succeed in preventing death from delphinia if the artificial respiration has been delayed and neglected.

The therapeutical indications of delphinia are suggested by the physiological action of this alkaloid on the sensibility; it may therefore be employed in neuralgia, and perhaps in certain hyperæsthetic affections or in neuralgia of the fifth nerve. As to the mode of its administration, the internal use will be preferable to subcutaneous injections, on account of the insolubility of the alkaloid in pure water. The maximal dose of 1 milligramme ($\frac{1}{100}$ of a grain) may be repeated every two hours until the effects become manifest.

The external application cannot have much anodyne power, the absorption of the medication being almost *nil*; besides, it is by its action upon the bulbous portion of the medulla that the specific effects are produced.

Reviews.

A PRACTICAL TREATISE ON RENAL DISEASES AND URINARY ANALYSIS. By William Henry Porter, M.D., etc. Containing one hundred illustrations. New York: William Wood & Co., 1887.

For ten years, the author tells us, he has had ample opportunity for studying the various lesions of the kidney, and the ideas advanced by him are based upon the results of over one thousand autopsies. He has endeavored to present the subject of renal disease not only from the pathological and clinical point of view, but also from the physiological stand-point. The work opens with a brief but clear *résumé* of the anatomy and physiology of the kidney. The diseases of these organs occupy the greater part of the volume; there is also a chapter on diabetes, and a concluding section on urinary analysis in its widest sense.

Diseases of the kidney are studied under the headings of "acute parenchymatous metamorphosis, or acute parenchymatous nephritis," "chronic parenchymatous meta-

morphosis," embracing the three forms of large white kidney; "acute diffuse nephritis," "chronic diffuse nephritis," embracing the three forms of the disease. Chapter V. treats of "complications of renal lesions and treatment of chronic diffuse nephritis."

Acute and chronic sclerosis, gouty kidneys, hyaline, albuminoid, or waxy kidneys, with a summary, form the topics of Chapter VI.; the remainder of the first section embracing chapters on Renal Hemorrhage, Hæmatoglobulinuria and Anæmia, Acute and Chronic Congestion, Pyelonephritis and Pyelitis, Pyonephrosis, Hydronephrosis, Renal Calculi, Chronic Atrophy and Hypertrophy, Cysto-Scrofulous Kidneys, Infarction, Fat Embolisms, Pyæmic Emboli, Sarcoma, Adenoma, and Lipoma, Parasites, and Glycosuria.

This summary will give an idea of the general arrangement of the book; as for its actual character and value, it must be said that the author has done the mere literary part of the work well; his descriptive writing is clear and forcible.

The diagrams of the different renal diseases are carefully and minutely drawn. In discussing treatment the author is far more satisfactory than the generality of writers upon renal diseases. He does not generalize as many do, and after describing many varieties of diseases mass the treatment of all in one comprehensive paragraph. In acute diffuse nephritis, *jaborandi* seems to be his main reliance, either in the drug or its alkaloid; from observing a large number of cases he deduces "that it is not depressing to any notable degree, and is always followed by most desirable results." Its action he concedes should be very carefully watched. *Digitalis* is the remedy of the acute state. The potassium salts are contraindicated. Opiates cannot be used in the uræmic attacks of children, and iron in tincture of the chloride only when it tends to assume the chronic form.

In the parenchymatous metamorphosis of pregnancy, which he calls the second form of large white kidney, the author relies mainly on a modified Basham's mixture, giving ether or chloroform to prevent the return of convulsions, and he considers pilocarpine as useful to the mother, since it "undoubtedly causes the rapid expulsion of the child," "apt to be still-born," but it will often save the mother's life.

The chapter on "Complications of Renal Lesions" presents one of those extremely-useful articles which give us a view of the

relations of diseases with each other. Were the author to base his claims for respectful hearing upon this chapter alone he would not be unwise. Especially valuable are his hints for the treatment of intercurrent disease, the bronchitis, the cardiac lesions, the asthma, dropsy, constipation and diarrhoea, eczema, erysipelas, and the gastric affections. In oedema of the larynx he suggests a trial of O'Dwyer's tubes. In peritonitis, often a disease of renal origin, opium, he says, "while it may decidedly improve the peritonitis increases the strain on the renal organs." "Will the kidney's epithelium stand this extra strain?"

This question has a direct bearing upon abdominal surgery. Cases have occurred within the author's observation where, with rapid repair going on in the abdominal incision and intra-peritoneal wound, the patient had yet died with "symptoms commonly classed as septic." Close investigation revealed "a rapidly developing acute parenchymatous metamorphosis of the kidneys." The bladder in all these cases contained urine showing albumen and abundant characteristic casts. If, then, after abdominal operations, when on the second or third day certain symptoms enumerated by the author make their appearance, "copious draughts of simple or medicated waters" be given, the quantity of urine will be increased. Albumen and casts disappear, and the threatened septicaemia vanishes. The author gives us his theory of the causation of this condition of the kidneys after operation. Anæsthesia, the increased necessity for elimination, the often unavoidable use of opium, these are his main factors. In renal pneumonia, "free and early cardiac stimulation by ammonia and alcohol." Ergot is useful in steadying "the contraction of the arterioles;" digitalis should be avoided as causing heart-failure. Uræmia is very carefully studied in this chapter. A pill of caffeine, strychnine, and digitalis is recommended; "but for a quick action," Basham's mixture with spiritus eth. nit. Where there is a "nervous element," which the author takes some pains to explain, he gives us a tonic, a mixture of nux vomica, damiana, and gentian, upon which he evidently places great value, and which he recommends in other conditions and frequently refers to.

The chapter on "Parasites" is well illustrated. In "Glycosuria" the author gives the result of numerous autopsies, and has written a chapter of great interest and value. Some of his views are novel. He divides the

disease clinically into the temporary, the mild, and the severe. The relation between the failure of digestion in advanced glycosurics and the increase of kidney-lesion, shown by casts and albumen, is dwelt upon at some length. In these cases, if the condition of the kidney can be improved, the digestive symptoms will disappear and the appetite return, showing, he thinks, that the failure in digestion was not the result of overstrain of the digestive organs from the limited diet, but from difficulty of elimination. Very excellent diet tables are given, which, however, present no new points of interest. The diet-list of Professor Andrew H. Smith is also given. The second section of the work is devoted to "Urinary Analysis," and goes over the ground thoroughly. The student and practitioner can turn to him as a guide and manual on the subject without fear or disappointment. The illustrations of microscopical examinations are good, and the text is suggestive everywhere with diagnostic points, which render the second section more valuable. In short, the book is one which cannot be read carefully without giving us some more complete idea of renal disease, and from its perusal one surely must rise somewhat better fitted to engage in the struggle with a group of diseases more misunderstood and more insidious perhaps than any other with which the medical man is brought in contact.

E. W. W.

DIE MORPHIUMSUCHT UND IHRE BEHANDLUNG. Von Dr. Albrecht Erlennmeyer. Dritte vermehrte und verbesserte Auflage. Mit 22 in den Text gedruckten Holzschnitten.

Berlin C., Leipzig, Neuted, Heuser's Verlag (Louis Heuser), 1887.

Most German medical books portray in the poorness of their paper and general make-up the frugality of the German nation. The present volume is evidently an *édition de luxe*. With its broad margins and its large clear type, it appears almost like a new departure in medical literature. Evidently Dr. Erlennmeyer is a successful book-writer or practitioner, and likes to see his offspring arrayed like unto Solomon in all his glory. In the nearly five hundred pages of the work the whole subject of the morphia-habit is treated in a most detailed manner. Indeed, a work of such magnitude upon so small a theme could not, we think, in this country have met with financial success, let its merit be what it would. The fact that the first edition of the treatise was exhausted inside of six weeks and the

second in four years, shows that the Germanic mind is much exercised upon the subject of the morphia-habit.

The book is divided into nine chapters. Of these the most interesting are the third and fifth, in which are respectively discussed the symptoms and treatment of the morphia-habit. Specially worthy of note in the second chapter we find the report of a case in which fatal tubercular poisoning is believed by Dr. Erlenmeyer to have been produced by infection with the hypodermic needle. A physician, aged 38, who had been accustomed to use the same syringe for himself and a tuberculous patient, died suddenly, and at the autopsy a tuberculosis, strictly localized to the peritoneum, was found. A fact, of which we confess we had not before had knowledge, is that children born of morphia-eating mothers are practically morphia-eaters, and during the first days of their life, unless morphia is given to them, are very apt to suffer collapse. This condition may end in death, and seems to be parallel to sudden giving out of the system which sometimes follows the sudden withdrawal of the alkaloid in the adults. Several cases are related on page 45 in which newborn children, in such collapse, were apparently saved by hypodermic injections of morphia. Dr. Erlenmeyer asserts that whilst sugar is frequently found in the urine after acute poisoning, it is never, or very rarely, present in chronic morphia-poisoning.

In the fifth chapter three methods of treating the morphia-habit are discussed in detail. The first of these methods is that whose central idea is the sudden and complete withdrawal of the morphia. Under these circumstances violent delirium is very prone to occur, and is not rarely accompanied by severe and even fatal collapse. On account of its danger this method of treatment is condemned by Dr. Erlenmeyer. Another plan of treatment, which is also condemned, is the very gradual withdrawal of the morphia. The method which is favored is a rapid but not sudden denial of the alkaloid to the patient. When the habitual dose has been not over seven grains of morphia a day, the alkaloid is to be withdrawn entirely in the course of six days. When the quantity has been greater than this, ten or twelve days may be required. Under such rapidity of withdrawal collapse is said never to occur. Burkart's experience, that the hypodermic users of morphia yield much less rapidly to treatment than do those who take the alkaloid by the mouth, is confirmed by Erlenmeyer. The experience of

the writer of this review distinctly coincides with that of Dr. Erlenmeyer in believing that the best treatment of the morphia-habit is to be found in the rapid but not immediate withdrawal of the poison. The use of cocaine for relief during the first period of abstinence is condemned by Dr. Erlenmeyer.

In conclusion, we can commend this book to any one who is desirous of a sumptuous volume, containing all that is known in regard to the opium-habit. The bibliography at the end of the book contains a descriptive list of two hundred and sixty papers and books upon the subject.

DIFFERENTIAL DIAGNOSIS. A MANUAL OF THE COMPARATIVE SEMEIOLOGY OF THE MORE IMPORTANT DISEASES. By F. Dehavilland Hall, M.D., Assistant Physician to the Westminster Hospital, London. Third American Edition. Thoroughly revised and greatly enlarged. Edited by Frank Woodbury, M.D. Philadelphia: D. G. Brinton, 115 South Seventh Street, 1887.

The present volume is a book of two hundred and fifty pages, in which it is attempted to give the diagnosis of all of the diseases, not surgical, to which flesh is heir. In spite of the use of tables, and double columns of fine or coarse print, the effort is scarcely a successful one. No doubt the student or the ill-informed practitioner may glean from the pages a good deal that is to him of great importance; but there can be no comparison between the book and that of Professor Da Costa upon the same subject. Upon looking over the diseases of the nervous system with a good deal of care, we find much that, according to our thinking, is not exactly correct. Thus, the statement on page 87, "The high temperature of cases of sunstroke serves to distinguish such from the coma of apoplexy," is, in its unqualified condition, simply incorrect. Very high temperature may be present in an apoplexy. Then, again, the diagnosis between cerebral hemorrhage, cerebral thrombosis, cerebral embolism, although compiled from various authorities, is not accurate. Pain in the head is in no sense a characteristic of cerebral hemorrhage as opposed to cerebral thrombosis. There frequently is loss of consciousness in cerebral thrombosis, and almost as frequently no loss of consciousness in cases of slight hemorrhages. The recovery after cerebral thrombosis is certainly no more slow than after cerebral hemorrhages, as would seem to be indicated by the text before us. Then, again, spastic cerebral hemiplegia, spoken of on page 100, is not an equivalent of poli-encephalitis;

although, as this subject is a very obscure one, an error here is excusable. The portion of the book which treats of the respiratory apparatus seems to us to be more satisfactory than that which discusses diseases of the nervous system. The fact that the work has reached its third edition indicates that it has met a want, but we sincerely hope that it has not taken the place of more elaborate treatises upon the same subject.

A REFERENCE HAND-BOOK OF THE MEDICAL SCIENCES.
 Edited by Albert H. Buck, M.D., New York City.
 Volume V.

New York: William Wood & Co., 1887.

With commendable regularity the successive volumes of this great work follow one another. The one before us commences with Miliaria and ends with a very elaborate article, from the pen of Dr. E. H. Bradford, upon Pott's disease. On looking over the volume we find that it presents the same characteristics as those which have been previously published. To us it is especially valuable on account of the curious out-of-the-way information which it contains, often upon subjects of great practical importance. The first article that attracted our attention, probably on account of its numerous illustrations, is one upon poisonous insects. Reading it over, we felt assured that it must have been written by the well-known American entomologist, Mr. Charles V. Riley, a conclusion which was confirmed by reference to the end of the article. In this paper are described, with anatomical and scientific exactness, all insects, from the mite to the tarantula, or the great centipede, that are capable of injury to men. Some of these creatures we trust our readers may never make acquaintance with. Especially will the big bedbug of Arizona strike terror into the heart of the Eastern housewife, if ever it finds its way into civilization: nimble-footed, enormous in size, armed with a beak nearly the fifth of an inch in length, this pest causes in its victim a convex wheal an inch or more across, followed by great pain and itching, and after some days a discharge of pus.

A very elaborate article, learned and interesting, is that by Dr. J. N. Mackenzie, of Baltimore, upon neuroses of the nose. We have not time to follow the discussion, in which he reaffirms the correctness of his well-known belief that in that portion of the nasal mucous membrane which covers the turbinated corpora cavernosa there is a sensitive spot whose irritation produces a reflex cough, whilst the remaining mucous membrane of the

nose is almost insensitive. The discussion which this theory or alleged fact has given rise to is stated by Dr. Mackenzie with commendable fairness.

In previous notices we have called attention to the value of the descriptions of Health-Resorts and Springs scattered through the work. Volume V. conforms in this as in other respects with those that have preceded it. As an instance of an excellent climatic article, we notice one by Dr. H. Richards upon New Mexico, immediately followed, as it so chances, by articles on New Orleans, Newport, New South Wales, and New York City, all from the same pen.

LESSONS IN GYNÆCOLOGY. By Wm. Goodell, A.M., M.D., Professor of Clinical Gynæcology in the University of Pennsylvania, etc. Third edition, thoroughly revised and greatly enlarged, with one hundred and twelve illustrations.

Philadelphia: D. G. Brinton, 1887.

The author by no means considers this work as a complete treatise. Its teaching is very largely clinical, and the aim of the work practical in the extreme. It is a mirror of the author's system of class instruction, and illustrates his somewhat peculiar gifts as a teacher and lecturer. The present third edition is much enlarged, containing six entirely new lectures and many new illustrations. Perhaps the distinguished author has done no more useful work than in writing the chapter on "Nerve Counterfeits of Uterine Diseases," and in the decided stand that he takes everywhere against unnecessary uterine "treatment." Throughout the volume the author's descriptions of cases lend an additional interest to the didactic matter. The illustrations are clear, plain, and easy to comprehend, and to the operator will prove invaluable.

A MANUAL OF THE PHYSICAL DIAGNOSIS OF THORACIC DISEASES. By E. Darwin Hudson, Jr., A.M., M.D., etc.

New York: William Wood & Co., 1887.

There are many excellent manuals within reach of the student and practitioner, and yet this volume strikes us as somewhat unique and as deserving attention. It recognizes, as does no manual of diagnosis within our remembrance, some of the real difficulties in auscultatory diagnosis, as, for example, the distinction between pleural and pulmonary crepitant and subcrepitant râles. Not that other writers are ignorant of the difficulty, but rather that they treat it as a small matter, and one by no means likely to prove trouble-

some to diagnosticians of their calibre. The author, however, in this and many other instances, admits that to err is human, and his rules for avoiding error in such cases seem to us better, clearer, and more intelligible than usual.

The illustrations in the book are also excellent, and impress the eye, so that a mental picture of dulness areas is retained long after the page is turned. There are no useless words, but a study of clearness in expression. The author believes in the "Ellis line" of dulness in pleural effusions in a majority of cases, but does not go into the theory connected with it, so ably illustrated in the experiments of Garland,—a theory which, it seems to us, if once accepted, necessitates a restudy of the whole question of pleural effusions. The chapter on "Synopsis of Heart-Disease" will be found extremely valuable to the student.

E. W. W.

VON ZIEMSEN'S HANDBOOK OF GENERAL THERAPEUTICS. Volume VI., ELECTRO-THERAPEUTICS. By Wilhelm Erb, M.D. Volume VII., THERAPEUTICS OF CIRCULATORY DERANGEMENTS. By Professor M. J. Oertel, M.D., of Munich.

These two books complete this so-called "Handbook of Therapeutics," which is really a work of a succession of monographs covering almost all methods of the treatment of disease not connected with drugs. These two volumes are fully up to the standard of those which have gone before them, and especially is the work of Professor Oertel of importance. In an editorial in the October number of the GAZETTE, reference was made to the labors of Professor Oertel.

THE MEDICAL ANNUAL AND PRACTITIONER'S INDEX. A WORK OF REFERENCE FOR MEDICAL PRACTITIONERS. Edited by Percy Wilde, M.D., 1887.

Bristol: John Wright & Co. London: Hamilton, Adams & Co., etc.

This is a convenient and attractive epitome of practice, both surgical and medical, wherein are introduced, together with the standard and orthodox modes of treatment, all the discoveries and improvements of the past year. Owing to its alphabetical arrangement and its plain head-lines, it is easy to find anything in a moment. A somewhat extended perusal of the book convinces us that it is all that its editor claims, and will prove a great assistance by giving at a glance a thorough digest of the year's advance on any desired subject. Authorities are given in all cases, long citations where necessary, and the small size of the volume will allow of its being carried in the

pocket. Such a book, kept at hand and read at spare moments, would do much to bring the hard-worked rural practitioner fully up to the standard of his more fortunate brother, who has, perhaps, more time, more access to journalistic literature, and inhabits some medical centre where it is as hard to fall behind as it is in the country to keep up with the rapidly increasing knowledge of the day.

E. W. W.

Correspondence.

BERLIN.

(From our Special Correspondent.)

On the 29th of September a stroke of paralysis ended the life of a man who was universally acknowledged by the medical world of Germany to be the leading surgeon of the times.

Bernhard von Langenbeck, the indefatigable and persevering investigator, the inspiring teacher of the academic youth and of the physicians of our nation, the most magnificent operator of the day, the great-hearted humanitarian, the high-minded and noble gentleman, the most genial colleague, and the winner of highest honors, is no longer among the living.

Foreign countries mourn with us the loss of our great surgeon, and surely many of the readers of this journal will recall with gratitude the hours when they were privileged to listen to the instructions of our departed teacher; America also, who sends yearly a large number of physicians to the German clinics to complete their education.

Bernhard v. Langenbeck was born on the 9th of November, 1810, at Horneburg, in the province of Hanover. He was the nephew of the famous surgeon and anatomist, Konrad Johann Martin Langenbeck, who, until 1851, had worked for nearly half a century at the University of Göttingen. Langenbeck also studied in Göttingen, and took his degree of Doctor of Medicine in 1835. He then made a scientific visit to France and England. On his return he domiciled himself in Göttingen as *privat-docent*. He was there made *professor extraordinarius*. In 1842 he was called to Kiel as *professor ordinarius* of surgery. He served in the war of Schleswig-Holstein against Denmark as general staff surgeon of the army, and had charge of the surgical service of the Lazarets. In the year 1847, in consequence of the death of Dieffenbach, he was called to

Berlin, and given charge of the royal surgical clinic.

This clinic at the time contained twenty-eight beds, and under his régime grew to what it is to-day,—one of the first and largest surgical clinics in the world. Again, during the campaign against Denmark in 1864, Langenbeck was called to the position of surgeon-general, and in the same year was raised to the nobility. He also took part in the Austrian campaign (1866), and in the Franco-Prussian war (1870-71) as consulting surgeon. In 1882 he gave up his professor's chair in Berlin and went to Wiesbaden, where he remained until his death. During the last years of his life he rarely even attended calls for consultation. It was only a year ago that he suffered from cataract, which, however, was successfully operated upon.

Langenbeck's scientific renown is especially in the field of operative surgery, and it was he who first brought the conservative principle of surgery into practice. His resections and methods of osteotomy, his plastic operations and tenotomies, are still deemed worthy of imitation.

Besides this, his activity during the different campaigns in which he took part enabled him to gather his experiences in a series of works, which secure for him the deserved title of the first army surgeon of the world. No books refer to the work Langenbeck did as an operator, and the history of his skill can only be handed down to posterity by those who listened with interest and wonder to his teachings, and who have stood by him at the operating-table. There is hardly any class of surgery in which he did not work in a new and often highly original manner. The students who worked under his tuition are scattered far and wide over the globe, and their names echo loudly the renown of their great master, at whose feet they once sat.

Esmarch, W. Busch, Billroth, Hueter, Schoeborn, Trendelenburg, Gurlt, Luecke, these are a few of those who once were his assistants. The Surgical Congress of Germany and the Medical Society of Berlin, of both of which he once was president, have determined to hold a grand memorial celebration in honor of the great departed surgeon in the spring of next year.

During this autumn over in America the greatest interest was aroused in reference to the International Medical Congress, which, according to the accounts of several journals here, was half a failure. At the same time, among the many conventions held, the Con-

vention of German Physicians and Naturalists took the first place. This learned society (which meets every September) was founded in the year 1822, principally through the efforts of Okens, in Leipzig. Since then it has met regularly for sixty years, except during war times or when cholera was raging in the country.

The organization of the society is a thoroughly free one. It has no standing committee. Every branch society chooses a meeting-place for the next year, and appoints two business managers, upon whom is devolved the entire business of the convention. Anybody can become a member who has proved himself to be a writer and investigator in some branch of medicine or natural sciences.

These meetings of physicians and natural scientists become yearly the centre of attraction to the scientific world of Germany. They bring together at their meetings from one to two thousand members. Of course the number depends somewhat on the place of meeting. When the convention was held in Berlin over four thousand members were present. Austria is always represented very largely, also Switzerland, the Netherlands, and other neighboring countries.

As in the International Medical Congress, so also in our convention, articles of general interest only are read in the general meetings, while articles on any special scientific subject are placed in their respective departments. The number of these articles read during this last year's meeting, which occurred at that well-known watering-place Wiesbaden, was twenty-eight. The managers of the society this year were the chemist R. Fresenius and Dr. Arnold Pagenstecher. Among the lecturers at the general meetings were Virchow, the chemist Wislicenus from Leipzig, Pryer, professor of physiology at Jena, Professors Meynert and Benedict from Vienna, and the well-known bacteriologist Hueppe. The convention lasted for one week, and was combined with many festivities, which were pleasant interruptions to the work. Besides this there was a very large and complete exhibit of scientific instruments and apparatus, also plans, charts, and models, and pharmaceutical preparations.

These were contributed by some five hundred exhibitors, and formed a most interesting part of the programme, and gave a very good idea of what technique has done during the last few years for the advance of scientific investigation, for the teachings of natural sciences, and for hygienic medicine and surgery.

We can only give a sketch of the pharmacological part of the exhibition. Among the exhibitors were nearly all the leading German manufacturers,—E. Merk, of Darmstadt; Eugen Dieterich, of Helfenburg; Jaffe and Darmstädter, of Berlin; and many foreign firms, as well as the great firm of Burroughs, Wellcome & Co., of London.

Among the exhibition of prepared drugs we found quite a number of novelties. A heart-poison, *strophanthus hispidus*; several antisiphilitics, *solanum paniculatum*, *jacaranda lancifolia* and *mimosifolia*, *tribulus lanuginosus*, *francicea uniflora*; one antiepilepticum, *capparis soriacea*; stomachics, *erodia fraxinifolia* and *aletris farinosa*; a remedy for diabetes, *eugenia jambolena*; a new remedy for asthma, *atherosperma moschata*; a remedy for intermittent fevers, *chionanthus virginiana*.

The new German colonies in West Africa sent *nucis kolæ*, which contains two per cent. of caffeine, and is, therefore, recommended in neuralgia; also *nucis cali*, which are said to be similar to *sem. Calabar*.

There were several drugs which have come into favor last year, among which we must mention the *hydrastis canadensis*, which seems to have permanently established itself in the practice of medicine.

Concerning the “*pharmacopœia elegans*,” the German manufacturers are continuing to strive with increased energy to perfect their preparations, and to satisfy all demands, not only for outward form and appearance, but also for taste and assimilation. America is somewhat in advance of us in this line. Still, several of the preparations which we have introduced are coming more and more into favor; the “*fluid extracts*,” for example.

The exhibition also showed the great advance recently made in dermatological preparations, this department being very complete and containing much new material. While formerly only official pharmaceutical preparations were compounded in the laboratories, now the manufacturing of *dermatotherapeutic* remedies has become a specialty in itself.

New remedies, such as *ichthyol*, and new salve bodies have been discovered. The place of the old-fashioned fat is taken by *vaseline*, *lanolin*, soap, and, lastly, by *mollin*,—a mixture of fat and glycerin. Then a new specialty is springing up in the soap industry,—viz., the preparation, principally by means of centrifugalization, of a perfectly neutral soap, in which various drugs and remedies may be incorporated; also the manufacturing of the

American rubber plaster, which was so quickly introduced here, has become a German industry.

The science of therapeutics owes a great debt of gratitude to organic chemistry, which of late has been taking immense strides, for having supplied it with a number of new remedies, some of which are still in a state of probation and experiment. Foremost among these are the new derivatives of *benzol*. Among these a veritable bonanza of antipyretics and antiseptics seems to have been found. While the base derivatives containing nitrogen seem to be of service as antipyretics, those free from nitrogen and containing oxygen seem to have greater antiseptic properties. Some derivatives, however, seem to be efficacious as both, as, for example, *salol*. Formerly it was thought that the more complicated derivatives of *benzol* (such as the *chinolin* and *pyridin* group, from which also the neutral alkaloids are supposed to be formed) principally contained antipyretic properties. It now, however, is proved by *acetanilide* (*antifebrin*), which has been so recently taken up, that also the simple and perhaps the most base derivatives of this highly interesting body also contain antipyretic properties. Another interesting derivative of *benzol* is the recently discovered acid called *sulphinid saccharin*; and now, as such quantities of this drug are in the market, it will soon be shown to what an extent this acid has the power of replacing sugar, in diabetes, for example. The *menthan* group has also contributed new material to therapeutics, especially *hypnotica*, and of which the latest (hydrate of *amylen*) is still undergoing further experiments.

Electro-therapeutics was also wonderfully well represented at this exhibition. The collection of surgical instruments was also very complete, and various different novelties in the different specialties—ophthalmology, laryngology, rhinology, gynecology, dentistry, etc.—were shown.

Besides this convention of physicians and naturalists there were a series of special conventions taking place during September in Germany. In Frankfort-on-the-Main there was a convention of specialists of insanity and brain-diseases, and in Heidelberg there was a meeting of the Ophthalmological Society. This last-named society, by the way, celebrates its twenty-fifth anniversary next year, and purposes then to hold an international ophthalmological convention in Heidelberg. After the flood-tide of interest caused by the convention, which, during the

autumn months, is an all-absorbing topic to the medical and scientific world, somewhat subsides, quiet, but equally as intensive and active work begins again among the local societies. In my next letter I purpose to report to you on the first session of the Medical Society of Berlin (Berliner Medicinischer Verein), which is already hard at work.

Finally, let me make mention of an important investigation which has recently been taking place in the hygienic institute of Dr. Koch, which will be of special interest to the readers of the THERAPEUTIC GAZETTE, as the worker is one of their countrymen, Dr. Ernest Laplace, of New Orleans.

Laplace carefully examined the "sublimite bandage," which is being so extensively used in the practice of surgery, to ascertain, firstly, whether it was really germless,—that is, aseptic; and, secondly, whether it was also antiseptic. The result of his investigating experiments showed that the most of the bandages examined proved to be in conformity with the first condition. However, he found that when the sublimate came into contact with substances containing albumen, in consequence of the residue of mercurial albuminate which was formed, the antiseptic properties (which it otherwise has when not in contact with albumen) were hindered and lessened.

To prevent the formation of such a residue, Laplace added acids to the solution of sublimate, and found that a certain amount of tartaric acid had the desired effect. To a five per cent. solution of the sublimate two per cent. of tartaric acid should be added, and the neutral gauze bandage steeped in this solution, then wrung out and dried. When this bandage was brought in contact with serum or blood containing pus-bacteriae, these were always killed. This bandage was practically tested by Dr. v. Bergmann in several surgical clinics with great success. Even when used on discharging and sloughing wounds it always remained sterile.

The employment of tartaric acid with sublimate in solution in the preparation of bandages is of great importance in the practice of surgery, and should be most highly recommended, as the full actions of the sublimate are thereby retained, by means of the acid, even in the presence of fluids or discharges containing albumen.

The tartaric sublimate bandage does not interfere in the least with the simultaneous employment of other dressings or remedies, such as iodoform, caustic, etc. This has been proved by careful experiment. The wounds

are not irritated by it. For the treatment of fresh wounds Laplace recommends washing and irrigation with the following solution :

R Sublimate, 1;
Acid. tartaric., 5;
Aqua dest., 1000.

The bandage should be prepared with—

R Sublimate, 5;
Acid. tartaric., 20;
Aqua dest., 1000.

The bandage or cotton-wool must be neutral and entirely free from all fat, and should be soaked in this solution for about two hours, then carefully wrung or pressed out, and then dried. The sublimate dissolves better in the acid solution than in the pure water. The solution will readily cling to the fibre of the bandage without injuring it in any way, and renders it perfectly germless. Four quarts of the solution will be enough to impregnate one hundred metres (about one hundred and twenty yards) of bandage.

PARIS.

(From our Special Correspondent.)

An important investigation on *colchicum*, *colchicine*, *colchicine*, and *hermodactyls* has just been completed by Dr. J. V. Laborde, of the Academy of Medicine, and M. A. Houdé, a pharmacist of the first class. They have succeeded in devising a good process for extracting *pure crystallized colchicine*, and practical methods for its *quantitative estimation* in the drug and its preparations, as well as for its *detection* in animal tissues for *medico-legal purposes*. Their mode of extraction is a novel one, as they avoid the use of mineral acids and acetic acid, alkalies and alkaline earths, all of which change colchicine into colchicine, a comparatively inert substance, or, at least, much inferior in medicinal virtues. They operate as follows: Powdered colchicum-seed is exhausted by percolation with about three times its weight of alcohol of ninety-six degrees. The percolate is filtered, and evaporated in vacuo at a low heat till the last traces of alcohol have been driven off. The residue, consisting of two layers,—one a watery liquid and the other an oily substance, lighter and nearly twenty times as bulky,—is shaken in a separator with a five per cent. solution of tartaric acid, the operation being repeated until Mayer's test no longer affords a white precipitate with the

washings. In this way the oily substance, which contains most of the colchicine, yields it to the acid solution, whose effect is possibly to decompose the oleate of colchicine there probably existing. The acid liquors are next shaken with ether, perfectly free from alcohol, to remove coloring-matters, traces of oil, etc. (colchicine being insoluble in ether), and then agitated with successive portions of chloroform till exhausted. The chloroform of the solution is now distilled off, and the brown residue redissolved in the smallest possible quantity of chloroform, and petroleum benzine of sp. gr. 0.620 is cautiously added in very small portions, until all the coloring-matters have been separated, and a limpid, colorless solution results. Finally, the liquor is left to evaporate spontaneously, and in a few hours colchicine, crystallized in long white needles, is obtained. One feature of this process is that no alkali is used; another is the addition of benzine, which, by the way, is a delicate point, as benzine, after at first separating the impurities, will, if added in too large a proportion, end in separating also the colchicine from the chloroform solution. Colchicum-seeds afford thus 3.35 per thousand of crystallized colchicine, and the root 0.45. All the parts of the plant contain more or less of the active principle, the fresh flowers ranking between the seed and the corn. Hermodactyls were also found to contain colchicine, a fact confirming Professor Planchon's opinion that the drug sold under this name in commerce is derived from a colchicum, probably the *C. variegatum*.

The behavior of crystallized colchicine with reagents, etc., was found to agree in general with the description already given by investigators operating with the amorphous principle. There is, however, a remarkable exception, namely, the ferric chloride test recommended by Dragendorff as affording a permanent green coloration. Messrs. Laborde and Houdé disagree from this opinion, and say that the green color does not appear with pure crystallized colchicine, but only when it is contaminated with colchicine. Indeed, they consider the test a very sensitive one for detecting minute quantities of colchicine, even when mixed with large proportions of colchicine. Another contrast between the two substances is, that while colchicine is intensely and persistently bitter, colchicine hardly presents any bitterness, unless when contaminated with colchicine. To pass briefly over the chemical history of the substance, suffice it to say that M. Houdé considers colchicine a nitro-

genated neutral principle with the formula $C_{44}H_{77}NO_{14}$ ($\sigma = 16$), from which colchicine differs by the loss of an equivalent of methylic alcohol. Experiments having proved that the change of colchicine into colchicine is accompanied with the formation in the presence of acids of a methylic ether, there is good ground for regarding colchicine as a methyl-colchicine, just as codeine is nothing else than a methyl-morphine.

For *toxicological researches* the following process is recommended: The organs, well divided, are exhausted by maceration with alcohol of ninety degrees, holding some tartaric acid in solution; the spirit is distilled off in vacuo; the residue, after filtering out the fatty substances, is shaken repeatedly with chemically pure chloroform; and finally spontaneous evaporation yields pure colchicine in the amorphous state. Although simple, the method is guaranteed to be reliable and sensitive. Most of the poison is found in the stomach, the bowels, the liver, and the pancreas; the saliva and kidneys contain least, while the blood never shows a trace.

The Pharmacy of Colchicum.—The foregoing renders criticism easy respecting pharmaceutical preparations of colchicum. Messrs. Laborde and Houdé condemn, for apparently good and sufficient reasons, all preparations made with acetic acid; they would also discard all preparations from the tubers and all wines of colchicum; the first because too unreliable, and the second because they have not succeeded yet in estimating the colchicine therein contained by their general process of extraction. Only the three following galenicals are considered worthy of retention, namely, a tincture of the fresh flowers, made with equal weights of the drug and alcohol of ninety degrees; a tincture of the seeds, from the finely-powdered drug and five times its weight of eighty per cent. alcohol; and finally an extract of the same, made by exhausting the powdered seeds with eighty per cent. alcohol, and evaporating the liquor at a low heat to the consistence of a soft extract, care being taken to keep in all the resinous and fatty substances, as they hold most of the colchicine. The doses for twenty-four hours are as follows: Of the tincture of fresh flowers, 10 grammes ($2\frac{1}{2}$ drachms), corresponding to 5 milligrammes of colchicine; tincture of the seeds, the same, equivalent to 7 milligrammes; extract, five pills of 3 centigrammes ($\frac{1}{2}$ grain), representing 5 milligrammes of the active principle. But, in preference to all preparations, granules containing 1 milligramme ($\frac{1}{100}$

of a grain) of crystallized colchicine are recommended, also a wine, and a solution for hypodermic uses.

To conclude with the therapeutics proper of colchicine, Dr. Laborde considers it a sure cure and preventive of gouty affections in all their forms. When the fit is well on, he advises, for the first day, four granules of 1 milligramme, given at fifteen minutes' interval; for the second, three granules; for the third, two; and the fourth only one. Then stop the medication for six or eight days, and begin it again in the same manner, if necessary. As a preventive, when a fit is felt to be imminent, he begins with three granules, and decreases the quantity as above. He says he has never failed, but it must be borne in mind that the climate of France is eminently favorable to the cure of gouty affections.

Some scepticism begins to be felt in regard to *kephir*,—the fermented milk,—so much extolled at first. Any other ferment than the true Caucasian was declared to produce a vulgar beverage, not to be compared with genuine kephir, as it did not contain the characteristic bacillus. But now Dr. Levy, of Haguenau, has demonstrated that the same result can be obtained by following the usual method for preparing kumyss, an opinion shared by other scientists. M. E. Reeb proposes the subjoined ready process: To milk, freshly curdled and thoroughly beaten, add two per cent. of simple syrup, and place the whole in a strong bottle securely corked, which is kept for three or four days at a moderate temperature. The beverage is now fit for use. It is sparkling, and has a peculiar pleasant flavor of its own. To hasten fermentation, the sugar may be previously interverted by ebullition with a small quantity of citric acid. Prepared in this manner, kephir contains about two per cent., by volume, of alcohol.

A curious incident, which took place at a recent meeting of the Belgian Academy of Medicine, shows the *utter disuse of bleeding* by modern practitioners. Dr. Willems related before the Academy that, a short time since, having been called in consultation with a younger brother physician, he suggested to bleed the patient, when his *confrère* declared he was quite unable to perform the operation, as he never had seen it practised in hospitals. Dr. Willems's statement astonished another academician, who expressed some incredulity as to such a state of affairs. "Well," said Dr. Willems, "I have no reason for concealing the name of the physician in question. It

is Dr. Van Bellighen, a graduate of the Ghent University."

Tanacetic rabies is a new name proposed by Dr. Peyraud, a consulting physician at the Vichy springs. Having observed the effects of oil of tansy (*tanacetum vulgare*) on rabbits and other animals, and noticed the similarity of the symptoms with those of true rabies, he considers the foregoing appellation an appropriate one to designate the singular disease artificially produced. When two drops of oil of tansy are injected into the veins of a medium-sized rabbit, the animal, after twenty seconds, is taken with convulsions, and presents a series of symptoms, the most characteristic of which are violently biting any object offered, and exacerbation of the fit when a mirror is turned towards its face. There is also an unnatural appetite, and the mouth, œsophagus, and stomach are found full of bits of straw. Two birds, having been exposed to the vapors of oil of tansy, had, one a fit of biting rabies, and the other a fit of paralytic rabies. Other animals were experimented with, and with similar results. But, not to enter into lengthy particulars about anatomical examinations, etc., suffice it to say that the symptoms, taken altogether, are not of the epileptic but of the tetanic type, most especially the rabic variety. The chief difference is, that the disease cannot be inoculated. From oil of wormwood and Japan camphor oil of tansy differs by its stopping the glyco-genic function of the liver. Another contrast is with bromide of potassium, which prevents the convulsions caused by wormwood and camphor, but is ineffectual with tansy. Dr. Peyraud's observations were presented to both the Academy of Sciences and the Academy of Medicine. At the first they passed without remark. But at the Academy of Medicine (October 18), Dr. Colin, a professor at the Alfort Veterinary School and a member of the Academy, objected to the application of the name rabies to the series of accidents brought on by tansy, adding that many therapeutic agents can produce symptoms similar to those of the rabic virus, and yet no one so far has thought of calling them rabic symptoms. "I see no reason," he said, "to change this way of doing. I gave dogs Hoang-nan, and observed therefrom a paralysis comparable to that of paralytic rabies, yet I was careful not to say the case was one of Hoang-nan rabies." Whatever may be thought of Dr. Peyraud's proposed name, his discovery must be admitted to have some importance at present when such bitter discus-

sion is raging, because it shows there are substances producing in animals symptoms that much resemble hydrophobic rabies.

PARIS, October 21, 1887.

THE DANGERS OF ANTIFEBRIN.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In answer to Dr. Winnett's question in your last issue, permit me to say that I have several times witnessed cyanosis produced in women patients by three or four $\frac{1}{4}$ -gramme doses of antifebrin. Have not seen it act so on men. Probably the nervous and circulatory systems of the latter can better resist the depressing effects of this drug.

F. M. BAUER.

220 EAST EIGHTY-SIXTH STREET, NEW YORK,
October 6, 1887.

Notes and Queries.

PEROXIDE OF HYDROGEN.

We have received the following from an occasional correspondent:

"This is comparatively a new remedy, but a most active one. The H_2O_2 is the most positive antiputrefactive agent known; it should head the list of all others in arresting septic processes, both constitutional and local. According to good authority by comparative tests made, it is sixty times more potent as an antiseptic than carbolic acid, twenty times that of salicylic acid, and forty times more than sol. bichlo. mercury. These statements may seem to be exaggerations, but my experience with the remedy, after testing it in a variety of diseases of a septic character, only confirms the statements made by others. In diphtheria its dissolving (oxidizing) effect on the exudations is wonderful. Applied locally to the membrane in the throat this is removed in a few hours, and all the fetor destroyed and the mouth and throat rendered *aseptic*. Administered by inhalation and taken into the stomach, it destroys sepsis, vitalizes the blood by giving off oxygen to it, reduces high temperature, keeps intact the strength of the nervous system,—a want which frequently causes death by heart-failure. In this class of diseases the H_2O_2 can be administered with other indicated remedies.

"If a decomposed egg be mixed with a small quantity of a fifteen-volume solution of H_2O_2 , an active effervescence will take place, and the odor of the sulphuretted hydrogen be at once dispelled; when brought in con-

tact with pus or putrid meat the same active effervescence will be observed, and the odor will be instantly destroyed.' My experience with it shows that it promptly disinfects all forms of putrid excreta and destroys at the same time all septic germs. The foulest and most putrid cavities it renders *aseptic* and entirely void of unpleasant odor. It is adapted to the syphilitic as well as the simple ulcer. When applied to a foul sloughing ulcer, a sluggish wound, or to an oozing carbuncle or open felon, not only is the pus destroyed but the sore is thoroughly cleansed and rendered *aseptic*. 'It is the most powerful antiputrid application known. Observed under a microscope, the rapidity and thoroughness with which H_2O_2 acts upon pus-corpuscles and bacilli is clearly seen. The corpuscles at once lose their spherical form, shrink, assume a concentric shape, and become heaped up as a mass of detritus, and in a few seconds the bacilli are transformed into a dead mass.' Its range of applicability is a wide one. I have used it in dressing wounds with better results than any other remedy. In fact, I have often been surprised to see some lacerated wounds heal (almost) by first intention under a three- or four-volume solution of the peroxide of hydrogen. In typhoid, scarlet, and other fevers it is a *sine qua non*, which should be administered both internally and applied externally as a wash to cleanse the skin of all septic matter, which is an active factor in rendering the fever continuous and malignant in type, etc.

"I have jotted down these thoughts that the members of the medical profession might become more intimately acquainted with this *most* active remedy. For I am led to believe that but few members of our profession know anything of the great curative properties of the peroxide of hydrogen. And for the want of this knowledge the remedy is left in the hands of charlatans to compete with scientific men in the profession whose remedies are less potent and efficient than this. Hence the advantage the quack has over the scientific physician."

EPHEDRINE.

Chlorhydrate of ephedrine is a new mydriatic alkaloid obtained from *Ephedra vulgaris* by M. KINROSSUKE MINRA. It has to be employed in a solution ten times more concentrated than homatropine, but it is much less costly. It does not paralyze the accommodation for near vision.—*Lancet*, October 15, 1887.

SYNTHESIS OF PILOCARPINE.

MESSRS. HARDY AND CALMELS have announced (*Compt. Rend.*) the success of their efforts to prepare a second natural alkaloid by synthesis. As a starting-point the authors used "*b*-pyridino *a*-lactic acid," a derivative of pyridine which had previously been recognized among the decomposition products of pilocarpine and described by them. The first stage was the conversion of this compound into pilocarpidine. To effect this it was treated with hydrobromic acid and gold chloride, by which the lactic acid was reduced to propionic acid, and a bromoauric compound of *b*-pyridino *a*-propionic acid obtained. This was decomposed with hydrogen sulphide, and the syrupy acid set free was heated in a sealed tube with a solution of trimethylamine. The contents of the tube were afterwards brought to dryness, and the residue treated with aqueous solution of potassium carbonate, when oily drops separated that proved to consist of pilocarpidine. The conversion of pilocarpidine into pilocarpine was eventually attained by oxidizing an iodomethylate of pilocarpidine with silver permanganate, the products being formic acid and pilocarpine. From physiological experiments made on dogs with the synthetic compound its action appears to be identical with that of the natural alkaloid.—*Druggists Circular and Chemical Gazette*, October, 1887.

THE PHARMACOLOGY AND THERAPEUTICS OF METHYLAL.

We add the following to what we have already published as to the action of methylal.

M. PERSONALI, of the Pharmacological Laboratory of Turin, published a note on the pharmacology of methylal in the *Giornale della real Accademia di Medicina di Torino*, 1886, page 295, in which he showed that methylal administered by subcutaneous injection, introduced into the stomach, or inhaled, has a sensible hypnotic action upon various animals—frogs, rabbits, pigeons, white mice, guinea-pigs, and dogs—in doses varying from 1 to 5 grammes per kilogramme of the weight of the animal. He described the sleep induced as profound; the reflexes were abolished, and there was a diminution in the frequency but an augmentation in the amplitude of the respiratory movements; the heart acted more rapidly, and there was a fall in blood-pressure; the temperature was lowered and the activity of the nutritive process was lessened. He then proceeded to study the an-

tagonism of methylal to strychnine, and by its employment succeeded in suspending the tetanic convulsions and saving the life of an animal poisoned by strychnine. He found that methylal acted promptly, was rapidly eliminated, caused no appreciable disturbance, and fulfilled most of the conditions required in a hypnotic.

MM. Mairet and Combemale have continued M. Personali's investigations as to the physiological action of methylal, and have studied also its therapeutic application in mental disorders. The experiments performed on different animals by subcutaneous injection, by ingestion (into the stomach), and by inhalation gave the following results. The hypodermic injection of methylal caused extreme pain, and might even produce syncope; injected pure, it might lead to ulceration; when doses of from 25 centigrammes to 50 centigrammes per kilogramme of the weight of the body were used, slight salivation occurred; and from a quarter of an hour to an hour after the injection, the animal lay down and slept. The sleep was calm, but the animal remained sensible to external excitants, though the reactions were slow. When the dose reached 50 centigrammes per kilogramme of the weight of the body, the sleep was deeper, and required a much more powerful excitant to interrupt it. The animal could thus sleep several hours; on awakening it was heavy and lazy, but soon recovered. Between 50 and 70 centigrammes per kilogramme of body-weight, sleep was overpowering, the animal fell asleep eating or in the midst of its natural enemies, and an intense peripheric excitant was required to obtain even slow and feeble reactions. Other phenomena also appeared; the pupils were dilated and the muscular fatigue approached nearly to paresis, so that the animal jumped with difficulty and could not hold up; there was a high pulse at the outset and very marked salivation; these symptoms disappeared after several hours, and then sleep persisted along with the characters given above; at this period a slight lowering of the temperature occurred. After injecting more than 2 grammes per kilogramme of body-weight, two distinct phases of intoxication were produced; in the first depression with somnolence; paralysis, first of the hind-quarters, then becoming progressively general; hyper-excitability of the muscles and sometimes spontaneous convulsive spasms of the limbs; general and sensorial sensibility was retarded and diminished; the pupils were dilated; there was lowering

of the temperature; the frequency of the pulse was slightly augmented and respiration was difficult and intermittent; the hairs were erected. Two or three hours after the commencement of the experiment the second phase appeared; paresis disappeared or became much diminished, the other symptoms improved, and the animal lay in an ordinary sleep. On awakening, the secretion of urine, which had been suspended, was resumed, the animal remained depressed and without initiative, it had no appetite, lost flesh, and required several days to recover. With these large doses the gravity of the symptoms varied according to the resistance of the animal, and death might ensue; a guinea-pig succumbed after receiving an injection of 2.35 grains of methylal per kilogramme of its weight. The necropsy showed a general congestion of the brain and medulla, punctiform hemorrhages in the pulmonary parenchyma and in the myocardium, a marbled appearance of the liver, and congestion of the cortical substance of the kidney.

Introduced into the stomach methylal produced the same effects, and sleep was induced by the same doses but not so quickly; it did not take place until two or three hours after absorption, and lasted somewhat longer.

When the drug was administered by inhalation, the animals showed the same symptoms, but when the dose was large, irritation of the mucous membrane of the eyes, nose, and bronchial tubes ensued, causing a flow of tears, sneezing, and cough.

These experiments appear to show that the general effects produced by methylal are essentially the same, whatever mode of introduction be adopted, but that sleep is somewhat more persistent when it is introduced directly into the stomach. The effects on different animals were the same, but the higher the animal ranked in the scale of beings, the more decided was the hypnotic action; thus one-half the dose necessary to cause sleep in a dog or a cat sufficed to induce it in a monkey; guinea-pigs did not actually sleep, but were only drowsy. Lastly, it would seem that the elimination of methylal is very rapid, particularly by the lungs. To sum up, although powerful doses of methylal produced toxic effects, going on even to death, the principal action of this substance in comparatively weak doses is to induce sleep, the doses required being from 25 to 50 centigrammes per kilogramme of the weight of the animal. Methylal therefore is a hypnotic which is rapidly eliminated, leaves no ill effects after awaken-

ing; does not accumulate in the system, and has but little toxicity unless taken in large doses.

MM. Mairet and Combemale have also studied the therapeutic action of methylal upon persons affected with mental alienation of different forms; their results are embodied in a note read to the Académie des Sciences on April 24, 1887. The sweet taste and ethereal odor of methylal and its solubility in water render its administration easy; it was given in an ordinary julep. Doses of from 1 to 8 grammes never caused gastric or other disturbance, but it was remarked that those patients who now and then wetted their bed did so regularly while taking methylal. It was always administered by the mouth, and in one dose at bedtime.

The drug was given to fifteen patients suffering from mania and lypemania; to twelve cases of simple dementia consecutive to functional mental alienation; to three cases of delirium tremens; to three cases of dementia; and to seven cases of paralytic dementia. In many of these cases other hypnotics had been tried, so that comparisons could be instituted.

At the outset of simple mania methylal appeared to have no hypnotic action, although the dose was raised to 7 and 8 grammes; at the stage of complete development, during acute crises of violence, methylal in doses of from 5 to 6 grammes succeeded, on the contrary, in procuring during the first days a sound sleep, lasting all night. The sleep, generally continuous, was in some cases interrupted for a quarter to half an hour, but was afterwards resumed until morning. This result was obtained even in cases of extreme violence, but it was necessary to increase the dose. The action diminished slightly when the system became accustomed to the hypnotic, but on interrupting the medication for two or three days, methylal again produced the same results as in the earlier doses. In simple dementia consecutive to functional mental disturbance, the effects of methylal were uniformly favorable, no matter what the degree of agitation of the patient, if the doses were sufficiently high, 5 and even 8 grammes had to be given. In two cases only was there no good result, and in one of these cases the patient was refractory to all hypnotics; the other patient had cardiac disease, and was influenced only by digitaline. It was necessary in these cases also to increase the dose when the system became habituated to the hypnotic. There were three cases of alcoholic mania, in two of which methylal was entirely without

effect, or had but a slight effect. In the cases of dementia the hypnotic in moderate doses (3, 4, to 5 grammes) produced good effects during the first five or six days; afterwards the sleep was less persistent, and lasted only from five to six hours, even when the dose was augmented. Among the seven cases of paralytic dementia, two were refractory, the first took at first 5 grammes, and later on 8 grammes, and slept three hours only, then three, four, and five hours, but continued talking. All other hypnotics had equally failed. The second case was syphilitic. No effects whatever were produced, even by a dose of 7 grammes. The other cases obtained quiet and sleep to a satisfactory degree, no matter what stage of the malady had been reached. In these cases there appeared no signs of the system becoming habituated to the hypnotic, which continued to be given in the same doses (5 to 8 grammes) for eight days running.

To sum up, methylal, without effect in alcoholic mania and at the outset of simple mania, succeeds pretty generally in all other cases, but it is necessary sometimes to augment the dose when the system becomes habituated to it, or to interrupt its administration for two or three days. It is important to note that the action of methylal is purely somniferous. Its impression on the brain is evidently temporary, and it causes no depression. It causes no disturbance of the nervous or nutritive systems. It is certainly destined to render good service in therapeutics.—*Brit. Med. Journ.*, October 22, 1887.

PHOTOXYLIN.

In a previous issue we alluded to the use of photoxylin as a substitute for collodion. Since then we have received a number of queries as to what this substance is, how it is prepared, and where obtainable. The United States shipping laws prohibit the importation of this substance, which is practically gun-cotton, on vessels carrying passengers. DR. ELMER, of New York, however, publishes in the *American Druggist* for November, 1887, the following formula for its preparation:

Mann, of St. Petersburg, prepared his gun-cotton with sulphuric acid of but moderate strength. He took thirty-one per cent. of sulphuric acid of 1.830 to 1.835 sp. gr., twenty per cent. of nitrate of potash, and immersed the cotton in the mixture when 50° C., digesting it for twenty-four hours at 28°

to 31° C. The time of digesting can be extended to five or six days. When the temperature is kept at 50°, one hour will suffice.

A mixture of thirty-three per cent. of sulphuric acid of 1.80 sp. gr. and ten per cent. of nitrate of potash gave also good results.

Chili saltpetre (nitrate of soda) crystallizes easily in the mixture, and will not do on that account.

A NEW PEPTONE FOR SUBCUTANEOUS INJECTION.

Hitherto attempts to use peptone hypodermically had failed on account of the difference of composition which existed between their composition and that of the blood. It occurred, therefore, to M. Reynard (*London Med. Record*, October 15, 1887) to convert blood serum itself into peptone. He recommends the following formula: Pure serum albumen, 5 grammes; dialyzed pepsin, 75 centigrammes; distilled water, 75 grammes; and 19 drops of pure hydrochloric acid; the mixture to be kept at a temperature of 46° C. for three times twenty-four hours. At the end of this time the liquid product is clear, and does not precipitate on the addition of ferrocyanide acidulated with acetic acid. When purified by dialysis and concentrated, it is spread on glass, and evaporated to dryness on a water-bath. This peptone, peptonized by alcohol, is well borne when administered by hypodermic injection, and gives rise to no irritation.

THE *Western Pennsylvania Medical College* at Pittsburg began its second annual regular course on Tuesday, September 27, with a class of near one hundred.

The introductory address was delivered by the secretary of the faculty, Prof. W. J. Asdale.

Dr. Asdale congratulated the class that they entered as students of medicine at an auspicious time, that the *science* of medicine was rapidly developing, that grand and great achievements were promised in the near future, that a new pathology was being created on an endurable basis, and a new therapeutics is to be formulated.

This college requires an entrance examination, and provides a three years' graded course.

Its success has been unexampled.

POISONING BY CARBOLIZED COTTON-WOOL.

In a recent clinical lecture at the Hôpital des Enfants Malades, M. SIMON (*London Med. Record*, October 15, 1887) described an interesting case of acute poisoning by carbolized cotton-wool in a female child, aged 22 months, and also gave some useful hints as to the differential diagnosis of aphthous sore mouth, angina, scarlatina, and diphtheria. On February 6, M. Simon was called in consultation to examine a little girl, aged 22 months, who had, the evening before, presented a series of nervous symptoms (prostration, vomitings, cold extremities). The patient had been affected with submaxillary adenitis, and tincture of iodine had been applied. The tincture being very much concentrated, an ulceration of five to six centimetres in length was the result of its application. The family doctor was now called in, and iodoform gauze and carbolized cotton-wool was applied to the ulceration. The first dressing was made on February 3. The next morning the wound presented a much better appearance, but the general state of the patient left much to be desired. The mouth was dry, tears flowed, and there was evident coryza. The child was very excitable, and complained of pains in the head. Temperature, 38.8° C. (101.8° F.). Pulse frequent. On February 5 the child was taken with vomiting, which medication failed to arrest. The face became pale and the extremities cold, while the temperature rose to 39.6° C. (103° F.); prostration was extreme, and the flow of urine suppressed. The use of the carbolized cotton-wool was abandoned, the patient recovering entirely from the toxic symptoms at the end of thirty-six hours. Specimens of the urine passed during the attack, and which were as black as ink, did not give the characteristic blue color when treated with nitric acid and starch, making it evident that the iodine had played no part in the intoxication. According to M. Simon, the elimination of the urine having been arrested at the first moment, the carbolic acid was accumulated in the nervous centres, and afterwards came away, on the suppression of the carbolized dressing, in the black urine characteristic of the poison. Considering the great susceptibility of children to the toxic action of carbolic acid, M. Simon thinks that this medication should never be used in children under two years of age. M. Simon then proceeded to describe the signs by means of which a differential diagnosis may be made between aphthous sore mouth,

angina, scarlatina, and diphtheria. The presence of a rough elevated product, the outer edges of which are not sharply cut, like that of a watch-glass set in metal, indicates aphthous sore mouth; whereas in diphtheria the patch is smooth, flat, and depressed, surrounded by a raised mucous membrane forming a distinct outline. In scarlatina the tonsils present patches of thick matter of unequal size, elevated, well defined, and without tendency to spread, being confined to the natural depressions of the organ.

ACACIA DELIBRATA.

A Brisbane plant which DR. BANCROFT has examined is *Acacia delibrata*, in the pods of which he has found a saponin. Physiologically it was found to act as an irritant poison. It has a very disagreeable taste, and is soluble both in alcohol and in water.—*Australian Journal of Pharmacy*, p. 104; *Pharmaceutical Journal and Transactions*, October 1, 1887.

A CORRESPONDENT sends us the following, which will point to the need of some registration law in Missouri:

"The accompanying slip will give your readers, if you see fit to publish it, an idea of the class of men we have to contend with in the practice of medicine in Missouri. It was in the case of an old lady, aged 62, whom the "doctor" had been treating for pneumonia for a week, when they decided to discharge him. The following is a fac-simile of the memorandum he left for his successor, which, unfortunately, happened to be the writer:

Dr
I Prepared fever dro. Ver Verie 10 gt
Aconite 5 "
Syrup for Lungs Tareter 3me
Capicum
Acue
Shugar
for the Pouls 'Leptendrin
a smale Ipca
powder Capicum
at Night Rehubarb
oil & turpentine for the Bouls
& a smale dose of oil & turpentine ever 3 hours
P. J. Jack M.D.

"As might be expected, the woman was in a dying condition and passed away within a few hours.

"Such cases serve to show the results of a law that allows such ignoramuses to degrade the profession."

HYGIENIC THERAPEUTICS—A LECTURE ON HYDROTHERAPY.*

BY PROFESSOR DUJARDIN-BEAUMETZ, Paris, France.

GENTLEMEN:—I intend to devote to hydrotherapy four lectures. In the first I shall give the history of hydrotherapy; in the second I shall study its physiological effects and methods of application; in the third I shall examine the benefits which we are warranted to expect from it in the treatment

of chronic diseases; in the fourth and last I shall take up one of the most disputed points of hydrotherapy,—I refer to the application of cold water to acute febrile diseases.

I.

HISTORY OF HYDROTHERAPY.

Like kinesitherapy and massotherapy, hydrotherapy dates from the earliest history of all nations. Primitive tribes have always practised some mode of water-cure in their attempt to deal with the problem of disease. We see, even to-day, savage people living like the prehistoric man in the Stone Age, and using cold water as a means of cure in sickness. Thus it is with remedial intent that the native women of the Fiji Islands precipitate

* From advance sheets. An abstract of two lectures delivered in Cochin Hospital. Translated by E. P. Hurd, M.D.

themselves into the sea immediately after their confinement.

The popular traditional belief that bathing in cold water removes all impurities of the body has been transmitted from age to age, and has always taken a religious shape. What is the practice of the Hindoo who regularly dips himself in the sacred waters of the Ganges or the sacred lakes which surround his temples, what are the baths of purification ordered by the law of Moses and the Talmud, and the ablutions required by the Mohammedan religion, but examples of this early traditional belief?

In the history of the Greek nation we find also traces of these popular traditions in the earliest or mythical period of this history. Thus we read that Melanapus cured the three daughters of Proetus, king of Argos, by dipping them in the water of Anigrus after a march of ten leagues. The temples of Hercules, where the sick sought restoration and invigoration by immersions in cold water, represented this popular notion as to the efficacy of cold water. But we must come down to the time of the priest-physicians the Asclepiadæ, and in particular to Hippocrates, the father of medicine, before we find any distinct scientific teaching as to the physiological action of water, and you will find in the treatise of the latter on "*Air, Water, and Places*," in that on the "*Usage of Liquids*," and in the chapter on "*Diet and Regimen*," precise indications as to the employment of water in therapeutics.

But it was in the Roman period that the two founders of hydrotherapy—Musa and Charmis—appeared. Musa, like all the Roman physicians, was of Greek origin; physician to Augustus, he rendered himself famous by curing his imperial patron of a disease of the liver by cold baths, of which we have the following account in Suetonius: "During the whole course of his life he (Augustus) suffered at times dangerous fits of sickness, especially after the conquest of Cantabria, when, his liver being injured by a defluxion upon it, he was reduced to such a condition that he was obliged to undergo a desperate and doubtful mode of cure; for warm applications having no effect, Antonius Musa directed those that were cold."*

Augustus recompensed his physician munificently, and, besides a considerable sum of money, he presented him with a gold ring which conferred on him the order of knighthood, and he erected statues in his honor.

The method of Musa consisted in affusions of cold water after the use of warm baths and vapor-baths. Horace, in accordance with the advice of Musa, abandoned the warm baths of Baia for the cold-water douches and affusions of Clusium. There has been a long dispute as to whether Marcellus, also treated by Musa, owed his death to cold-water treatment; but it was Charmis who was the most rigorous and relentless in the application of hydrotherapy. Charmis was born at Marseilles, but he practised at Rome, and Pliny has given us the picture of Roman senators shivering under the influence of the cold baths which Charmis had ordered them to take. If Charmis was very severe in the application of his method, he showed himself, according to Pliny, to be very greedy of money: he exacted two hundred thousand sesterces (more than eight thousand dollars) as a fee from a patient who came from a distant province in order to consult him. Charmis, as well as Musa, lived in the first century of the Christian era.

The hydrotherapeutic practices excogitated by Musa and carried to excess by Charmis gave rise to protestations and widely dissentient opinions, and one hundred and fifty years later Galen left on record a summary of all these disputes by the numerous divisions which he established among the opponents and partisans of hydrotherapy. According to the physician of Pergamos, the practitioners of his time were divided into *hydrophiloï* and *hydrophoboi*. The *hydrophiloï* were subdivided into *psychrophiloï*, advocates of cold water, and *thermophiloi*, advocates of warm water. The first, the *psychrophiloï*, admitted three subdivisions,—the *psychrolites*, partisans of cold baths, the *psychropotes*, partisans of warm baths, and *psychropantes*, partisans of both modes of administration. Galen, moreover, was an advocate of cold baths, but he condemns their excess. He insists on the benefit which may be derived from cold water as a drink in fevers, and recommends ablutions of cold water to the head while the rest of the body is immersed in warm water.

Cœlius Aurelianus, who lived, or is believed to have lived, in the fourth century of our era, also indicates a new mode of employment of cold water,—namely, the application of sponges wrung out of cold water to

* "Destillationibus jecinore vitiato, ad desperationem redactus, contrariam et ancipitem rationem medendi necessario subiit, quia calida fomenta non proderant, frigidis curari coactus; auctore Antonio Musa" (Suetonius, "Vita Cæsaris-Augusti").

the stomach of melancholic patients. We have seen this practice revived in our day.

There are also in Aetius and in Alexander of Tralles, passages proving that these physicians made use of lotions and affusions of cold water in fevers. I may here remark that you will find in the voluminous compilation of Oribasus, which I have many times cited, all the usages of antiquity pertaining to cold baths.

Then came the epoch of the Middle Ages, and, as it was with all that pertained to the arts and sciences, everything came to a standstill, during this period of barbarism, for a thousand years, and we are obliged to come down to the middle of the sixteenth century before we find any further indications of hydrotherapeutic practices applied to the treatment of diseases.

It is a singular circumstance that the Arabian school of medicine, which, during this period of the Middle Ages, kept the ancient tradition, and upon which the religion of Mohammed rendered obligatory repeated ablutions with cold water, did not enforce these ablutions as a part of medical practice. Rhazes alone counselled cold baths, and this as a part of the treatment for smallpox. Rhazes, whose true name was Bou-Bekr-Mohammed-Ben-Zakarya-Errazy, besides cold baths in smallpox, ordered astringent baths and cold drinks for metrorrhagia, and iced rose-water for burns.

In the sixteenth century—that is to say, at the epoch of the Renaissance—the medical world was but little interested in the subject of cold-water treatment. At the same time, I ought to mention that in Italy, Mercurialis, the restorer of the gymnastic art, did not overlook the importance of cold affusions in febrile maladies, and in Spain, Nicolas Mor-danus dwelt at length on the usage of cold water and of snow in sickness. In France, Ambroise Paré applied cold water to surgery, and showed the benefits that may be derived from irrigation in the treatment of wounds.

But we must come down to the seventeenth century, and to the end of this century (1699), in order to find all these scattered notions as to the advantages of cold water summed up in a work entirely devoted to hydrotherapy, and it is an English physician, Floyer, who was the author of this treatise.* Floyer established at Litchfield, where he was practising medicine, the first institution for hy-

drotherapy, which consisted simply of two contiguous apartments. In the one sweating was obtained by wrapping the patient in warm blankets, in the other applications of cold water were made.

In the eighteenth century all these ideas as to the employment of cold water took more definite shape, and this whole question of the water treatment of disease began to be agitated among physicians. It was in Italy that the chief interest in the subject seemed to centre, and much excitement prevailed among the partisans and opponents of cold-water treatment, which a historian of the period characterizes in these words: "All Italy is crazy on the subject of cold water." This practice was brought into Italy by two Spanish monks, who ordered, in the treatment of diseases, the free drinking of ice-water (from six to forty glasses a day) and frictions with ice.

In Germany the Hahn family laid the foundation of hydrotherapy. The father of the Hahns, Sigismund Hahn, who was born at Schweidnitz, in that same Silesia which at a later day gave birth to Priessnitz, was an earnest advocate of cold water both internally and externally; but it was especially his son, Johann Sigismund, who in a manner laid down the principles of hydrotherapy, in a work which he published in 1743. He not only applied cold water to the treatment of chronic disorders, but also to acute affections and to exanthematic fevers, and in particular to smallpox, measles, and erysipelas.

His brother, Gottfried von Hahn, who practised at Breslau, and who was raised to the rank of nobility by the king of Prussia in 1717, did much less for hydrotherapy than his brother, and has left on record only the results of his practice.

At the same period appeared the first work in Russia on the usage of cold water, which the Russian people from time immemorial had made use of in sickness, and we owe this work to Samoilowitz, physician to the empress, Catherine II., who employed with success ice-water lotions in the treatment of the plague which raged at Moscow in 1771.

France did not remain idle in this scientific movement which led physicians to use cold water as a therapeutic agency. The surgeons, reviving the practice of Ambroise Paré, counselled the use of cold water in the treatment of wounds; and Récolin, Pibrac, De la Martinière, Louis, Poutier, Mopelier, Champeaux, Chambon, followed the example of Lamorier, of Montpellier, and Guérin, of Bordeaux, who,

* Floyer, "An Inquiry into the Right Use of Baths." London, 1699.

in 1732, vaunted the good effects of constant irrigation in the treatment of wounds. Three military surgeons—Lombard, Percy, and Larrey—made this a part of current practice in the treatment of wounds by fire-arms.

But the most ardent and vehement advocate of hydrotherapy was Pomme. All diseases of the nervous system were to him vaporous affections, and all were tributary to a uniform treatment, which consisted in immersing the patients for six, twelve, and sometimes twenty-four hours in water, kept at a constant low temperature of 10° C. [50° F.] by adding ice. According to Pomme, all vaporous maladies depend on "relaxation" or shrivelling of the nerves, and are to be combated by aqueous infiltration of those nerves, which swells them out again to their normal dimensions. Pomme, besides cold baths, subjected his patients to a debilitating regimen, giving them nothing but milk, barley-water, and chicken-broth.

But we must turn again to England if we would find a more rational and practical impulse given to hydrotherapy, and we owe this progress to Currie. Currie had a predecessor in this scientific movement by the name of Wright, who, in a voyage from Jamaica to England, had observed in his own person the good effects of cold-water applications during an attack of pernicious fever; he got well under the use of douches of sea-water, three painful at a time, and he thereafter applied these ablutions of cold water to the treatment of fevers, and typhus in particular, and published, in 1797, the results of his observations.*

Currie, who practised in Liverpool, profiting by the experience of Wright, put his typhus fever patients upon cold-water treatment, and reported a hundred and fifty-three cases in which the recovery seemed to be due to the plentiful use of cold water. He employed affusions of sea-water or salt and water.

But where Currie showed himself superior to all his predecessors was in the fact that he laid down the principles of the physiological action of cold water in the febrile process, and he made the first physiological experiments to determine how cold water acts in health and in sickness. In order to give more precision to his observations, he made use of the thermometer, which he placed either in the mouth or in the armpit of pa-

tients, employing for this purpose a very sensitive instrument, graded much like those of the present day, so that he at the same time established the basis of hydrotherapy, and was the creator of clinical thermometry.†

The work of Currie is the most important and the most scientific work of the epoch on hydrotherapy, and on many points later researches have in no way diminished the value of the observations made by the English physician. In his writings, in which on every page he shows the benefits which may be derived from the employment of cold affusions in the treatment of febrile affections, Currie complains of the very meagre results which had attended his efforts to inculcate therapeutic methods of the utmost advantage to humanity. Currie was fully justified by subsequent events in giving expression to this lamentation, for his contributions to medical progress were destined to be so completely ignored that more than thirty years after his death the discovery of hydrotherapy was attributed to the empiric, Priessnitz.

All these facts, then, had passed into oblivion, and the important labors of Currie, to whom indisputably belongs the honor of having established hydrotherapy on an experimental and scientific basis, had been without fruit, when at the beginning of the nineteenth century Priessnitz appeared; and what could not be accomplished by the efforts of the most celebrated physicians for eighteen centuries—from Musa and Charmis down to Currie—a humble peasant and farmer effected. From this moment, hydrotherapy found its proper place in medical practice, and so universally since then have the principles of this mode of treatment spread, that at the present time there is scarcely a physician in the wide world who does not daily have recourse to practices of hydrotherapy. I know not, gentlemen, whether, like myself, you have ever been impressed with the melancholy fact, illustrated by the modern history of hydrotherapy, that it takes years of time and toil on the part of the leaders in medicine before any progressive movement of great sanitary and therapeutic importance is duly recognized by the profession at large, and one has often occasion to remark how difficult a task it is, and how much combined individual effort it takes, to overcome the apathy and indifference of the busy prac-

* Wright, "Medical Facts and Observations." London, 1797.

itioner or lead him to forsake the ruts of established routine.

But, before speaking of the "healer of Grafenberg" (as he is called), and of his hydrotherapeutic methods, I must mention a work which made a considerable stir at the commencement of this century. I refer to the treatise of Giannini on the "Treatment of Fevers by Cold Water," published in Milan in 1805. The Milan physician adopted the teachings of Currie, and treated fevers by cold water, but he substituted for the practice of Wright and Currie, which consisted of cold-water affusions, immersions in a cold bath, in which he kept his patients from ten to fifteen minutes at a time. Giannini applied this treatment to all fevers. Cold baths in intermittent fever combat the paroxysms, and in typhus keep the fever below the dangerous point; these were facts which Giannini had experimentally determined, and it may truly be said that in his application of cold baths to typhoid fever he was Brandt's predecessor by more than fifty years.

Vincent Priessnitz was born July 4, 1789, in one of the poor huts of the village of Grafenberg, which is situated at eighteen hundred metres of altitude, between Glatz and Neiss, near Friwaldau, in the mountains of Austrian Silesia.

Of an observing mind, long accustomed to make use of water both externally and internally in the treatment of sick animals placed under his care, Priessnitz had occasion to apply this mode of treatment to himself before prescribing it for any other human being. In 1816 he was thrown from a vicious horse, and suffered severe contusion of the left arm, besides two broken ribs. The surgeon whom he consulted declared that consolidation could not be obtained in the fractured ribs. Priessnitz, leaning his chest against the corner of a chair, and holding his breath, brought the broken fragments together, and had them maintained in position by a tight bandage, which he kept constantly wet with cold water, and consolidation was speedily effected.

Priessnitz attributed his recovery to this water treatment, and thereafter, accompanied by his cousin, Gaspard Priessnitz, roamed up and down the various country places of Silesia, treating by these same methods sprains, fractures, and all sorts of wounds and injuries in men and animals.

The success which attended this treatment made a great stir, and the reputation of Priessnitz was established. The hardy mountaineers, mind you, did not attribute to the water

treatment the brilliant results which Priessnitz had obtained, but ascribed them to sorcery, while the physicians and veterinary surgeons denounced him, and the priests heaped upon him their anathemas.

Then his practice increased, and his methods underwent improvements, and soon from all parts of Europe patients flocked to Priessnitz to be treated. To accommodate this itinerant *clientèle*, spacious hotels were constructed, which superseded the poor hovels of the village of Grafenberg. The Austrian government, astonished at the success which attended Priessnitz's hydropathic mode of treatment, appointed a medical commission to examine into its merits, and this commission reported favorably, recommending its adoption by the medical profession.

Loaded with honors and become immensely rich, Priessnitz did not, however, seem to enjoy his good fortune; he encumbered his hydrotherapeutic practices with odd and incomprehensible formulæ to keep away the physicians who came from every quarter to learn his methods; he kept himself more and more aloof, and died without leaving any writings, or a single pupil worthy of him.

Priessnitz was guided by very strange physiological and pathological notions, not being a physician, and having never studied medicine. In his estimation, the body was like a sponge, more or less thoroughly impregnated by diseased humors, and the plentiful application of cold water internally and externally tended to wash out these humors and rid the body of its impurities. His mode of treatment comprised several particulars, to which I shall briefly allude. These were all summed up in regimen, aeration, and the internal administration of cold water. He absolutely proscribed all condiments, with the exception of salt. He also insisted that all food should be taken cold. No alcoholic beverages were tolerated at Grafenberg; tea and coffee were also interdicted. As for exercise, Priessnitz made a great account of it, but he forbade ordinary gymnastic exercises as likely to exhaust or otherwise do harm, and recommended joinery instead.

"At Grafenberg," says Schedel, "all the patients are provided with a saw, a saw-horse, and an axe. Young as well as old are compelled to split wood."

As for the internal use of water, the patients were obliged to drink from ten to forty tumblerfuls a day. Before dinner they drank four to six glasses, and two after dinner; the rest was drunk between meals.

Before applying cold water externally, Priessnitz had recourse to sudation. To obtain sweating, he wrapped his patients in warm blankets, and, when they were covered with perspiration, the cold-water applications were made. These were varied. There was, first, the full bath, in which the patient was immersed; then there was the partial-bath, in which the patient was placed, and water was splashed over him (this was followed by rubbing); next in order came the foot-baths and sitz-baths; and, lastly, the cold, wet compresses and the wet sheets. Priessnitz made little use of douches, employing only the jet douche.

Such was the complex treatment employed by Priessnitz, and which his inventive genius was able to vary to such an extent; and you will see, by referring to the work of Scoutetten, that the patients under his care were occupied from four o'clock in the morning in summer, and five o'clock in winter, till ten o'clock at night, in carrying out the many rules and directions of the empiric of Grafenberg.

From this moment hydrotherapy became a part of current practice in the different countries of Europe. Baldau, in France, in 1840, studied the methods of Priessnitz, and founded the first hydrotherapeutic establishment at the castle of the Arcade; then Scoutetten, in 1843, made known Priessnitz's methods; still later, Schedel, in 1845, published his work on hydrotherapy; while Lubanski, in 1847, made known the results of his observations at the hydropathic institute which he had founded at Pont-à-Mousson.* Lastly, Paul Vidar founded the great establishment of Divonne, Macario that of Lyons, Bottentuit that of Rouen, and Delmas that of Bordeaux, and thus a number of the cities of France came to be provided with hydrotherapeutic establishments.

But the institution which was destined to give to hydrotherapy its most scientific character was assuredly that of Bellevue, directed by Fleury, who opposed to hydrotherapy of an empirical nature a rational water treatment, the precepts of which are set forth in his remarkable work entitled "A Practical and Rational Treatise on Hydrotherapy," the first edition of which appeared in 1852.

* Baldau, "Practical Instruction on Hydrotherapy," Paris, 1846; Scoutetten, "Water in its Hygienic and Medical Relations: a Treatise on Hydrotherapy," Paris, 1845; Schedel, "A Critical Examination of Hydrotherapy," Paris, 1845; Lubanski, "A Practical Study of Hydrotherapy," Paris, 1847.

Fleury endeavors to place rational hydrotherapeutics at the head of physiological therapeutics, and bases his practice on physiological experiments conducted with the utmost scientific rigor. He repudiates the employment of warm water and tempered water, and abandons sudations, at least in part; but, on the other hand, he multiplies the forms of douches, and considerably augments the arsenal of hydrotherapy.

Having finished the historical part of our subject, we come to the physiological effects and clinical applications. This will be the topic of the next lecture.

II.

PHYSIOLOGICAL EFFECTS AND MODES OF APPLICATION OF HYDROTHERAPY.

The physiological effects determined by the application of cold water have been the subject of numerous works these late years, and from these treatises I shall glean the materials for this lecture. I must allude in particular to the interesting researches made in France by Delmas, of Bordeaux, by Thermes and De Bottey, of Divonne; to those of Fredericq, of Liège, in Belgium; and especial attention should be called to the memoir of Scheuer, of Spa. I must also acknowledge my obligations to the splendid work of Winternitz, of Germany, and the numerous and fruitful experiments of Roehrig, of Rosbach, and of Fleischl.† I shall take these works as my guide in the brief survey which I shall here make of the physiological effects of hydrotherapy.

In this lecture I shall study only the action of cold water in its momentary effects on the cutaneous surface, leaving to one side the prolonged effects of this agent which constitute its antithermic action; this latter subject I shall take up in the last lecture on hydrotherapy, which will be devoted to the treatment of acute febrile maladies by cold water.

When cold water is applied for a brief space

† Delmas, "Physiologie nouvelle de l'Hydrothérapie," Paris, 1880; Bottey, "Études médicales sur l'Hydrothérapie," 1886; Thermes, "De l'Influence de l'Hydrothérapie sur le Nombre des Globules du Sang," Paris, 1878; Scheuer, "Essai sur l'Action physiologique et thérapeutique de l'Hydrothérapie," Paris, 1885; Winternitz, "Die Hydrotherapie auf physiologischer und klinischer Grundlage," Wien, 1880; Roehrig, "Die Physiologie der Haut experimentell und kritisch bearbeitet," Berlin, 1876; Rosbach, "Lehrbuch der physikalischen Heilmethoden," Berlin, 1882; Fleischl, "Untersuchungen über die Geetze der Nervenregung," Wien, 1878.

of time (by douches, plunges, baths) to the integument, it causes a train of symptoms which all of you have experienced when you have taken for the first time a cold plunge. Under the influence of the cold application, the individual experiences at first a sense of distress which is sometimes very painful. The beatings of the heart become irregular; the respiration is interrupted; there is a sensation of chilliness which extends over the surface of the whole body; the skin becomes pale, takes on a purplish hue, and there is a general shivering. Then, with the cessation of the action of the cold, these phenomena rapidly disappear; there is now a sense of general comfort, the circulation becomes more active, the respiration fuller, the skin reddens, the surface becomes warm, and there is a feeling of vigor and resistance which is very pronounced. It is to the sum of these phenomena that the name of *reaction* is given. Such are the symptoms of the cold-water application when it is of short duration.

But in order well to understand the physiological effects of the cold douche, it is necessary to examine each of these phenomena separately, and this is what we will now do, taking up successively the action of cold water on the circulation, on the respiration, on calorification, on innervation, and on nutrition.

Under the first head, we shall have to examine the action of cold water on the capillary and peripheral circulation, then its effects on the heart, and, finally, its action on the composition of the blood.

With respect to the capillary circulation, the action of cold when it is but transient is very perceptible; it constricts the calibre of the vessels of the cutaneous net-work, then, when the action of the cold has ceased, to the primary contraction succeeds a dilatation which is produced at the moment of reaction. But in order to obtain this active contraction and the subsequent dilatation, the action of the cold must be of very brief duration.

It is by the intermediation of the nervous system and by reflex action that this constriction of the capillary net-work is brought about; it is, in fact, due to a twofold cause, since we now admit vaso-constrictor as well as vaso-dilator nerves. The transient action of the cold energizes the functions of the vaso-constrictors and inhibits the vaso-dilators; at the moment of reaction the opposite effect is produced,—the vaso-dilators enter into play and the vaso-constrictors are inhibited.

This knowledge of the effect of cold on

the peripheral circulation is based on rigorous physiological experiments. I will touch rapidly on those of Naumann and Schüller, and shall dwell more particularly on those of François Franck.*

Naumann's experiments were made on the frog. Separating all the parts of the posterior extremity so that the limb remained attached to the body only by the sciatic nerve, he applied cold or mechanical irritation to the member thus detached, and observed under the microscope the effects thus produced on the mesenteric circulation. He then noticed that whenever the excitation was slight, or the action of the cold transient, there was a diminution in the capillary circulation, while, on the contrary, when the action of the cold was prolonged or too severely irritating, there was a dilatation of the vessels. This experiment is, as you see, one of great interest. It sets in clear light the rôle of the nervous system in the modifications undergone by the circulation when, for a longer or shorter space of time, cold is applied to the cutaneous surface.

Schüller experimented on the hare. He applied cold to the exterior by throwing a jet of cold water upon the belly and back of this animal; then he watched the effects produced on the pia mater, and observed, as before, that when the action of the cold was of little duration, there was a contraction of the capillary net-work, which gave place to a dilatation when the action of the cold had ceased.

But the experiments of François Franck have furnished us data of the greatest interest and value with regard to the peripheral circulation: first, because they were performed on man, and, secondly, because he made use of an apparatus which enabled him to determine with mathematical accuracy and even to enregister the modifications of the circulation.

François Franck,† in his experiments, employs an apparatus devised by Buisson, a sort of *plethysmograph*, which is a modification of the apparatus which Piégu first invented for studying the movements of expansion of the limbs. The hand of the subject is placed in a hermetically-closed vessel full of water; it is immovably fixed in this vessel, and the augmentation or decrease in size of the member causes a variation in the level of the liquid,

* Naumann, "Untersuchungen über die physiologischen Wirkungen der Hautreize;" Prager, *Vierteljahrsschrift*, Band 77; "Zur Lehre von den Reflex;" "Reizen und deren Wirkung;" *Pflüger's Archiv f. Physiologie*, v., 1872.

† Labors Undertaken in the Laboratory of Marey, 1878.

which is transmitted by a registering drum. When to the right forearm of the subject ice is applied, while the left hand is fixed in the enregistering apparatus, there is produced at the end of two or three seconds a diminution in the volume of the left hand; this shrinkage increases little by little, attains a certain point, then gradually disappears, and at the end of a minute the hand has regained its former volume.

By an attentive analysis of the phenomenon, François Franck shows that it does not result from any primary action of cold on the heart affecting secondarily the hand, but from a reflex act, having its starting-point in the impression of cold on the skin of the right forearm, its point of reflection in the spinal cord, and its destination the vascular nerves of the left hand. Mosso has repeated these experiments with the same apparatus, and has arrived at the same results. This experiment sets forth clearly the action of cold when applied momentarily to the skin, showing with what certainty this agent effects the diminution of the peripheral circulation.

Physiologists have gone even further in the prosecution of researches of this sort, and Winternitz has endeavored to ascertain by experiments, rigorously conducted, what are the points of the skin which have, above all, an elective action on the circulation of a determined vascular area. He has shown that the application of cold to the foot occasions chiefly a fall in the intercranial circulation; cold applied to the thighs, on the other hand, affects most the pulmonary circulation, while cold to the back influences in a marked manner the pituitary membrane. These are facts of the utmost importance, which we shall utilize hereafter when we come to study the applications of hydrotherapy to local diseases. Chapman has even gone so far as to take this elective action of different parts of the spinal cord on the vascularization of certain organs as the basis of a therapeutic method, which consists in applying along the vertebral column and over determined points bags of hot water or of ice. Allow me also to remind you that the experiments of Winternitz give sanction to the popular practice of arresting nose-bleed by applying some cold substance to the back.

The action of cold water on the heart is also a subject of great interest, and has given rise to numerous experiments to which I ought to allude before going any further. Roehrig has given especial attention to this subject. He experimented on the hare, and on applying mechanical irritants or cold to the ear of

the animal, examined the effects produced on the heart, and he has thus demonstrated that transient cutaneous excitations augment the beatings of the heart, while strong or very prolonged excitations diminish the number of pulsations.* The experiments of Winternitz and of Delmas are still more conclusive, as these two observers made man their subject. According to Winternitz, when cold is applied to a limited surface of the skin, there is an increase in the beatings of the heart, lasting three minutes, then a progressive decrease.

Delmas undertook in 1869 and 1870 researches and experiments characterized by still greater precision, showing by tracings all the modifications which supervene when a douche is administered. As soon as the cold water touches the body the heart is violently excited, and the pulse becomes irregular and precipitate. To this augmentation of pulsations succeeds a diminution below the normal, a diminution which takes place and is prolonged during the period of reaction. These facts, gentlemen, are of great importance. They show, first, what risk we run in subjecting to hydrotherapeutic treatment persons suffering from cardiac affections. These dangers are not imaginary, and cardiopathic patients have been known to die suddenly under the first effects of the douche. Therefore Priessnitz, who had on more than one occasion witnessed disastrous consequences of this kind, resolutely refused to submit to the douche patients who complained of palpitations or of cardiac or pulmonary oppression. Not being a physician, he did not distinguish anæmic patients from those laboring under real heart-disease,—a distinction of the highest importance, for hydrotherapy is interdicted to cardiac patients, while positively indicated in anæmia. This leads me to speak of the effects of cold water on the composition of the blood.

It is to Thermes that we owe investigations which have given us our knowledge of this subject.† Making use of the processes of numeration and calorimetry devised by Hayem, and which have given a rigorous precision to his studies, he has shown that cold water augments not only the number of the globules, but also their physiological value.

The action of the douche on respiration

* Roehrig, "Die Physiologie der Haut experimentell und kritisch Bearbeitet." Berlin, 1870.

† Thermes, "On the Immediate and Mediate Influence of Hydrotherapy on the Number of Red Globules of the Blood." Paris, 1878.

has been much less studied, and the results of experimenters are contradictory. Johnson affirms that under the influence of a cold shower-bath of one minute's duration, the number of inspirations augments from two to eight per minute. Pleniger also has observed the same increase. According to Delmas, there is sometimes increase, sometimes diminution in the number of respirations, and there is no precise rule. As for myself, I have often witnessed these phenomena of the respiration under the influence of the douche, and can affirm that at the commencement of the douche there is first arrest of the respiration, then several long inspirations succeed, and when the period of reaction is established, the respiratory movements are augmented in number and intensity.

Naturally, this double action of cold water on the circulation and on the respiration entails modifications in calorification. But these modifications under the influence of the douche are at first but slight, for while one experiences a severe sensation of cold while the water is being projected upon the body, and of general warmth when the action of the cold has ceased, the thermometer scarcely indicates a fall of two-tenths of a degree. But what is somewhat singular, during the period of reaction this fall of the temperature goes on, and is the more marked if the individual takes exercise, and may attain one degree C. (the mean is 0.6° to 0.8° C.), continuing for two hours after the douche.

The experiments which Delmas has made with extreme exactness as the basis of these data are accepted as conclusive by all physiologists, and show us once more that it will not do always to assume the sensations of heat and cold which we feel at the surface as really indicative of the temperature of the body. Does not the period of chill in intermittent fever coincide with an elevation of the temperature? It is the same with regard to the effects of hydrotherapy, and while during the period of reaction it seems to us that the heat of the body has considerably augmented, and that this augmentation increases with movement, this is not the case, and the thermometer gives, on the contrary, a decrease in the bodily temperature.

Bottey ("Medical Studies in Hydrotherapy," Paris, 1886), in some recent experiments made to elucidate this subject, has shown that this fall in the temperature depends on the duration of the douche and the temperature of the water. When the douche is very cold (8° C. for example) and of short duration

(two to three seconds), the depression of the temperature is preceded by a short period of elevation,—one- to two-tenths of a degree,—but when the douche exceeds ten seconds we come under the conditions determined by Delmas, and the depression of the temperature, which varies from four- to five-tenths of a degree, is prolonged for several hours without any momentary reactionary elevation.

Hydrotherapy has a marked action on the nervous system. The reflex phenomena determined by the impression of cold on the skin bring into play the nerve-cells of the spinal cord, and effect an equilibrium between the cerebral and spinal functions. Cold applications also modify the cerebro-rachidian circulation, and we shall see that, according to the mode of application of the cold water, we may obtain either effects of excitation and tonicities or of sedation and calm.

Acting on the general and partial circulation, augmenting the globular richness of the blood, modifying respiration and calorification, determining effects of an indisputable character on the cerebral and spinal functions, hydrotherapy influences, in all these ways, the general nutrition, which it notably enhances; and Scheuer* has insisted long and justly on this point. He shows that the blood, driven from the surface under the first effects of the douche, is forced into the different viscera, and in particular into the hæmatopoëtic organs, then that it returns to the periphery during the period of reaction, when the enhanced activity of the capillary circulation augments the chemical combustions there taking place. All our tissues, then, participate in the invigorating action of hydrotherapy, and you readily understand how it is that we have found in cold water, thus applied in a sudden and temporary manner to the surface of the body, one of the most powerful means for energizing the general nutrition.

We come now to the usual modes of application of cold water.

Hydrotherapeutic processes are extremely numerous, and in order to describe them in a clear and methodical manner I shall be obliged to establish numerous divisions. One of these has to do with the force and pressure of the water, and we shall have to examine the processes of hydrotherapy with

* Scheuer, "On the Physiological and Therapeutic Action of Hydrotherapy in Chloro-Anæmic States," Paris, 1885.

pressure—*i.e.*, douches and affusions—and processes where the water is applied without pressure. Another division is based on the temperature. In fact, we restrict hydrotherapy largely to the application of cold water, and you will see that all the degrees of temperature of water are utilized, from ice-cold to hot-vapor baths.

Let us begin, if you please, with the first division,—*i.e.*, water utilized under greater or less pressure. To this head belong affusions, and especially douches.

Affusions are but little used; this is the primitive method which Wright, more than a century ago, employed in the treatment of febrile affections. You see this method still put in practice at the seaside sanatoria. It consists in pouring, or projecting with more or less force, one or more pailfuls of water over the naked body of the patient.

As intermediate between the affusions and douches properly so called, we may mention the *swan's-neck douches* and the *surge douches* (*douches en col de cygne et douches en lame*). The *swan's-neck douche*, which derives its name from the form of the tube which conveys the water, projects upon the neck of the patient a great volume of water. In the *surge douches* a considerable mass of water is made to fall upon the patient, giving him the impression of an enormous billow.

Douches constitute the most essential part of hydrotherapy, at least in France; for we may, in this respect, establish a difference between the hydrotherapeutic practices of this country and those of Germany. Faithful to the practice of Priessnitz, Germany makes great use of partial baths, of wet wrappings, and frictions with wet cloths, while little account is made of the douche. In France, on the other hand, under the influence of Fleury, the douche has taken a preponderant part in hydrotherapy,—so much so that the words are, with us, almost synonymous.

Douches are divided into general and partial; the general are subdivided into fixed and mobile douches. This division is based, as you see, on the different modifications which are effected in the pipe which serves to administer these douches, the word *pipe* (*tuyau*) being, in Italian, *dossia*, from which we have derived the name of *douche*.

The fixed douches the most employed are the shower-bath (*douche en pluie*) and the columnar douche (*douche en colonne*). Almost universal usage is made of the shower-bath. A sprinkling-ball (*pomme d'arrosoir*), furnished with a great number of holes, varying

from two hundred to three hundred, each having a diameter of from one to two millimetres, gives issue to the water, which falls in a fine shower upon the nude body of the patient.

The columnar douche consists in a vertical jet of water, which falls in a full stream, first on the head and then on the body of the patient. I shall not speak of the concentric spray douches (*douches en lames concentriques*), nor of the *sheet or bell douches* (*douches en nappe ou en cloches*), because they are but little in use at the present day.

As for the mobile douches, they are administered by means of a flexible tube with various terminal adjustments. The jet most employed is the simple jet, which may be broken either by means of the finger of the operator, or of a pallet adapted to the tip.

As for the partial douches, they are very numerous: vaginal douches, lumbar douches, rectal douches, etc.; all these douches are administered by a particular arrangement of the tubing, which enables one to limit to a given point of the body the action of the cold water.

There is a partial douche often put in usage, and described under the name of *circular douche* (*douche en cercle*). It is an apparatus which you will find in all the well-equipped hydrotherapeutic establishments, and consists in a peculiar framework, with a number of circles or rings, which deliver the water in a shower upon the body of the patient placed in the midst of these circles. There are stop-cocks which enable one to limit the action of the water to a given number of circles.

We come now to the action of water without pressure, and here we have two great divisions. Sometimes the patient is immersed in a certain quantity of water, sometimes the water is applied to the body in small quantity by means of sponges or cloths. The first subdivision is represented by the piscina and the bath. The piscina (*baignoire*) may be of greater or less size, with running or standing water. As for the bath, it varies also according to the circumstances, and may be general or partial, with running or standing water (foot-baths, sitz-baths, etc.).

Priessnitz made much use of the half-bath, and his practice is still in vogue in Germany. Glatz* affirms even that he derives good results therefrom in relieving the pains of tabetic patients. This is the way this bath is

* A Technical and Practical Study of Hydrotherapy. Paris, 1887.

administered: The patient is placed in an ordinary bath-tub partly full of cold water. During the bath the attendants make cold-water affusions over the whole body and practise energetic frictions with the water of the bath. The duration of the bath varies from five to fifteen minutes.

At other times the water is applied by means of a sponge. Lotions of cold water and sponge-baths have passed from the domain of medicine to that of hygiene, and the people of the north practise them constantly, especially the English, who, in their fondness for their bath-tubs, are in the habit every morning of taking a thorough rub-down with a sponge dipped in cold water.

At other times these frictions of the whole body are made with a cloth wrung out of cold water. On other occasions the entire body is wrapped in a cold wet sheet. This wet wrapping will render you great service in your private practice whenever, as in the country and in small cities, you cannot obtain the proper hydrotherapeutic apparatus. These cold-water wrappings are made as follows: You take a thick sheet, which you dip in a pail of cold water and wring out; then, the patient standing, you envelop him from head to foot in this wet sheet. In cases where there is tendency to congestions of the head, or in women where there are visceral congestions, you take care at the same time to immerse the feet of the patient in warm water. The duration of the wrapping ought not to exceed fifteen to twenty seconds. The wet sheet is then removed, the patient is wrapped in a dry dressing-gown, and by energetic frictions reaction is favored.

Just as we have general and partial douches, general and partial baths, so also these applications may be general or partial, constituting wet packs, half packs, wet swathes. Priessnitz made use of both sedative and excitant compresses; to obtain a sedative effect, the compresses were renewed so as to oppose reaction; to produce an excitant effect, they were left in place so as to determine a very active reaction.

The wet swathe consists in a large piece of cloth, long enough to go three or four times round the body; the end of the swathe is wet in cold water and then applied over the epigastrium and lower abdominal regions, and over this the remaining dry portion of the roller is passed in three or four turns. It is to the same process applied to the entire body that the name has been given of *wet pack* or *half pack*.

This is the way of applying the wet pack, or the half pack, the latter covering only the trunk and leaving the limbs free, the former, on the other hand, covering the whole body: On a hair mattress you spread a woollen blanket, and over this a wet sheet, which has been thoroughly wrung out of cold water. The patient is placed on this sheet, which is tightly wrapped around him, and over this is folded the dry blanket. You do not wish in this case to obtain the ordinary effects of cold, but rather a profuse sweating, therefore the patient is left in the wet packing two or three hours, diaphoresis being favored by spreading over all an eider-down coverlet. At other times the patient is simply wrapped up in a dry blanket and covered with abundant bedclothes; this is what is described as the *dry pack*.

As you see, gentlemen, hydrotherapy is not quite synonymous with cold water. It comprehends, on the contrary, applications of water at all grades of heat, and this is what leads me to the second division of my subject,—namely, hydrotherapy with water at various temperatures. But, in order that we may be agreed as to the precise sense in which modifications of temperature should be understood, I here reproduce Delmas's thermometric table, which gives the degrees on the Centigrade and Fahrenheit scales corresponding to the terms in common use in hydrotherapy:

	C.	Fahr.
Excessively cold.....	0° to 6°	32° to 42.8°
Very cold.....	7° to 10°	44.6° to 50°
Cold.....	11° to 15°	51.8° to 59°
Moderately cold (<i>fraiche</i>).....	16° to 20°	60.8° to 68°
Slightly cool (<i>allegourdie</i>).....	21° to 25°	69.8° to 77°
Tepid.....	26° to 30°	78.8° to 86°
Warm.....	31° to 35°	87.8° to 95°
Very warm.....	36° to 40°	96.8° to 104°
Excessively warm.....	41° to 60° or 70°	105.8° to 140° or 158°.

A given temperature may be constant during the douche or bath, or it may be made to vary. In the first case, we have the cold, the tepid, the warm bath; in the second, the Scot bath, the douche with decreasing temperature, the alternating douche, etc. If the cold bath is the most employed, you will see, as we go on, that the tepid bath, the warm bath, etc., may render us great service.

The douche with decreasing temperature is much in usage. It is especially applicable to nervous patients, who experience, under the influence of cold water, too great a shock, the bath being actually painful to them.

You begin the douche with warm water, and you rapidly lower the temperature by

bringing into play other (colder) jets, so that at the end of the douche the water is cold. This is an excellent mode of employing hydrotherapy in the beginning of treatment of delicate, sensitive patients.

The Scot douche, which is much in vogue, consists in employing water of 30° C. at the commencement of the douche, the temperature to be gradually raised to 40° C., and even to 50° C. For one or two minutes the higher temperature is maintained, then the *séance* is terminated by a cold-water douche of several seconds' duration.

In the "alternating douche" jets of warm water are made rapidly to succeed jets of cold water. Care is taken always to commence with the warm-water jets.

We come now to the applications of water in the state of vapor and to hot-air baths, which belong rather to the department of balneotherapy than to that of hydrotherapy; therefore I shall treat this subject very briefly. We have, first of all, the hot-air chamber, which is filled with hot moist or hot dry air, according as use is made for purposes of sudation of hot air alone, or of hot air impregnated with vapor of water. These closets may be of considerable size, so as to admit at the same time one or more individuals, or they may be mere boxes, in which the body and limbs are encased, the head remaining outside of the apparatus. The latter means of promoting sudation, to which the French term *étuves partielles* is applied (the general term *étuve* (stove) being used to designate the hot-air chamber), is one in very common use, though ordinarily, in private practice, a more simple way of effecting diaphoresis is employed. The subject is seated on a wooden chair, whose seat is perforated with from fifteen to twenty holes, and which is furnished with a vertical perforated board between the front legs of the chair and a stool for the feet to rest upon. The patient is then covered with blankets, which are made to enclose the chair as well; then underneath the chair is placed a spirit lamp, with numerous burners, capable of evolving a great amount of heat. Sometimes a basin of water is heated over the lamp, thus giving rise to a great volume of steam and constituting a primitive vapor-bath. This mode of producing sweating requires but simple apparatus, which can be extemporized on almost any occasion.

The administration of the hot moist-air baths may be briefly interrupted by a cold bath or a hot-water bath. The one constitutes the Russian, the other the Turkish,

bath. In the Russian bath, the patient is admitted into a hot moist-air chamber in which there are benches of variable heights surmounting each other. The higher the subject is seated on these benches the hotter the temperature, which varies between 36° C. and 75° C. [The steam is generated in Russia by pouring water on heated stones, but elsewhere, in a boiler, whence it diffuses itself through the chamber.] Then, when the whole body is covered with sweat, the patient takes a plunge in a tank of cold water, or else receives a cold douche.

The Turkish or Hamman bath is somewhat different. The patient, instead of entering a moist chamber, is admitted into a hot, dry-air compartment, with a temperature between 40° and 80° C. Then he is subjected to warm-water applications and a prolonged massage. These kinds of baths have of late years acquired considerable popularity, and you will find in Paris a great establishment which responds to all the exigencies of hydrotherapy and balneotherapy.

Lastly, I must remind you that there are vapor douches, which are administered by a flexible tube communicating with a reservoir in which the water is in a state of ebullition.

I shall have finished this long and tedious enumeration of hydrotherapeutic processes when I shall have mentioned the method of Chapman. You remember that I have told you before that ice has been vaunted as a hydrotherapeutic agent. Chapman has instituted a complete therapeutic system which consists in employing bags of ice containing one or more compartments, these bags to be applied over various regions of the spinal column, according to the organ which he desires to influence. Chapman has mapped out these regions with great precision, taking as his basis data furnished by the researches and experiments of Claude Bernard and Brown-Séquard, and utilizing our knowledge of all the medullary nervous centres. Such, in their aggregate, are the measures of hydrotherapy which are in usage. These methods may be all brought together under one roof, constituting a vast hydrotherapeutic institute, such as all our great cities now possess, or the principal and more important of these means may be employed in the houses of your patients by means of those movable apparatuses with which you are acquainted.

While recognizing the great advantages which the special hydrotherapeutic establishments present, and this not only on account

of the precision and the multiplicity of apparatus put in usage, but also, and chiefly, by reason of the skill, expertness, and general competence of the medical men at the head of these establishments, it must be owned that in a great many instances you may obtain just as good results with the mobile apparatuses or douches which to-day form part of almost all the bath-houses, while the more elaborate establishments have their special use in the more difficult and delicate cases.

Like every other therapeutic system, hydrotherapy has had enthusiastic partisans of certain exclusive modes of cold-water application, and while Priessnitz made especial use of the wet pack, of the half-bath, and of a rigorous regimen, we see Fleury and his school make almost exclusive use of the cold douche, rejecting entirely the warm or tepid baths; while still more recently, under the influence of Landry and Beni-Barde, warm and lukewarm douches are very much employed.

These varied modifications thus given to hydrotherapy are not merely the results of a passing fashion, but they also find justification, as Beni-Barde has shown, in the variable medical constitutions which have prevailed since the time of Priessnitz.

Who were the patients that flocked to Grafenberg at the time when Priessnitz was at his zenith of popularity? They were gouty, rheumatic people, high livers, and it is easy to understand the prodigious success which Priessnitz obtained in these cases with his hydrotherapeutic procedures, the rigorousness of his dietary system, and the forced exercise to which he subjected his patients.

Then, a little later, came Fleury, who found himself in the midst, not of gouty, but of anæmic people, to whom the cold douche, skilfully applied, brought a rapid amelioration. In our day, diseases of the nervous system predominate, and the number of neuropathic patients increases from day to day. Here the methods of Priessnitz and of Fleury completely fail, while, on the other hand, warm water fulfils special indications which relieve these nervous states. Hence the success of the method first advised by Landry and followed out by Beni-Barde.

I have finished what I had to say concerning the physiological effects of cold water and its different modes of application. In the next lecture we will try and turn these data to practical account, and will take up the indications and contraindications for hydrotherapy as applied to the treatment of chronic diseases.

CARBOLATE OF CAMPHOR.

By M. B. COCHRAN, M.D., SHONOND, WIS.

I USE this name because I know of no other that so fully describes the mixture under consideration. It is prepared by dissolving camphor in a ninety-five per cent. solution of carbolic acid to saturation. The carbolic acid will dissolve about three times its weight of camphor, and the resultant is a thin, clear, oleaginous mixture, having a strong odor of camphor and a very faint odor of carbolic acid. To the taste it has a strong and, at first, slightly-pungent flavor of camphor, but no flavor of the acid. Taken internally, in 10-drop doses, administered in capsules, it produces a sensation of warmth in the stomach which is not unpleasant, and which continues for an hour or two. When applied to the skin it produces a slightly-warm sensation for a few moments, and when applied to an abraded surface it smarts for a moment, and then all pain ceases. When two or three drops are injected under the skin a stinging is felt for a moment, which is followed by complete anæsthesia of the immediate neighborhood. When mixed with an equal quantity of cotton-seed oil, and applied to a fresh wound on gauze or cotton and kept well covered, no suppuration follows,—or has not when I have used it in this way. No vesication or pain follows its use when used in this way, or applied either to the skin or mucous surfaces. I have been using it for several months, and I submit a few cases in which it has been of marked benefit:

Mrs. P. came to me with herpes of the right leg,—numerous clusters of blisters over the entire leg and thigh, which were very painful. One thorough application of the mixture with oil caused an entire cessation of the burning, itching, and pain. No new clusters appeared, and desiccation began at once in the old ones, so that in four or five days the patient was well. Nothing else was used. I removed a large fatty tumor from the right arm of Mrs. P. The incision was five inches in length. I dressed the wound with carbolate of camphor and oil, applied on gauze, and it healed without pain or suppuration.

Wm. S. was struck with a knife, the blade of which entered the skin over the superciliary ridge of the right side, passed downwards, laying open the upper and lower eyelids, entered the eyeball on the lower side, and passed through the inferior orbital plate. He was brought to me, two weeks afterwards,

with a suppurating eyeball and lids ununited. The left eye was beginning to sympathize with the right, and was painful and sensitive to light. I removed the right eye, and dressed the wound with carbolate of camphor. All trouble of the left eye ceased at once, and no pain followed in the right; and in two weeks I fitted the patient with an artificial eye, and he returned to his home.

August A. came to me with his neck encircled with boils that were exceedingly painful. He had one also on his left wrist. Two of those on his neck and the one on his wrist were about ready to suppurate, and the others were just forming. I injected them all with carbolate of camphor, mixed with an equal quantity of sulph. ether. The pain ceased at once. Two on his neck and the one on his arm went on to suppuration, and, three days later, I opened them. The others were aborted, and he had no trouble afterwards. I gave him, however, a teaspoonful of a saturated solution of magnesia sulph. every morning before breakfast in a tumblerful of hot water.

Mrs. J. came to me with an acrid vaginal discharge that had existed for three years, which caused a vulvar eruption, with intense pruritus vagina. It followed the menopause, and her life had been one of utter wretchedness in consequence. She also had severe gastric catarrh, with profuse mucous discharge from the stomach. Anorexia, foul breath, and the fecal evacuations were horribly fetid. Her health was broken, and her nervous system in such a condition that her friends feared insanity. I gave her 5 drops of carbolate of camphor three times a day after eating, and applied carbolate of camphor on a cotton-ball to the os uteri once a week, leaving it for twenty-four hours, and following it with daily irrigations of the vagina with hot water. In about one week the foul breath left her, the abnormal fetor of the alvine evacuations ceased, and the pruritus was cured.

The foregoing are only a few of the cases in which I have used it. It melts readily with vegetable oils and with vaseline, mixes with sulphuric ether, dissolves salicylic acid, cocaine, iodoform, and in a solution of forty grains to the ounce of the latter hides its horrible odor. I believe that with it all the antiseptic properties of carbolic acid, camphor, salicylic acid, and iodoform can be secured without pain or irritation, and that its use, both internally and externally, may give us most excellent results.

November 2, 1887.

INTERMITTENCE IN DISEASE.*

By E. W. HOLMES, M.D., PHILADELPHIA, PA.

PERIODICITY is one of the most extraordinary of all vital phenomena. Linked with the earliest development, it continues manifest through all the varied phases of somatic activity, and ceases entirely only with life itself.

Intermittence has, by some, been limited to the peculiar functional activity inherent in the nature of an organ modified but not induced by external influences.

Periodicity would then only be occasioned by the presence anew of a pre-existing cause, external to the economy, and independent of its influence, its phenomena not being auto-genetic, but at each access occasioned anew by the primary cause.

Both terms express the idea of alternation, but intermittence rather gives us the impression of a temporary pause, or a failure of phenomenon, the cause being annulled, weak, or latent, while periodicity predicates a finished cycle, with a promise of return, the cause being enduring and efficient. Periodicity is, therefore, more properly applied to the evolutions of nature and the phenomena of health, while intermittence, as it were an evidence of debility, pertains to the rhythm of disease. Ordinarily, in the domain of medicine, the terms are not thus restricted, but are often used interchangeably.

An ostensible cause of physiological periodicity would be the influence upon us of seasonal and diurnal changes. Thus Darwin ("Descent of Man," p. 204):

"All vital functions tend to run their course in fixed and recurrent periods, and with tidal animals the periods would probably be lunar, for such animals must have been left dry or covered deep with water, supplied with copious food or stinted, during endless generations, at regular lunar intervals. If, then, the vertebrata are descended from an animal allied to the existing tidal ascidians, the mysterious fact that with the higher and now terrestrial vertebrata, not to mention other classes, many normal and abnormal vital processes run their course according to lunar periods, is rendered intelligible. A recurrent period of approximately the right duration, when once gained, would not, as far as we can judge, be liable to be changed; consequently it might be thus transmitted during

* Read before the Northern Medical Society of Philadelphia.

almost any number of generations. This conclusion, if it could be proved sound, would be curious, for we should then see that the period of gestation in each mammal, and the hatching of each bird's eggs, and many other vital processes still betrayed the primordial birthplace of these animals."

Again (*idem*, p. 31) :

"The homological construction of the whole frame in the members of the same class is intelligible, if we admit their descent from a common progenitor, together with their subsequent adaptation to diversified conditions. On any other view the similarity of pattern between the hand of a man or monkey, the foot of a horse, the flipper of a seal, the wing of a bat, etc., is utterly inexplicable. *It is no scientific explanation to assert they have all been formed on the same ideal plan.*"

A plausible assumption and withal enticing, but open to the objection which obtains against the whole doctrine of *radical* evolutionist theory,—viz., special pleading,—a deft incurvation of facts to suit a preconceived idea ; a proving of the assertion by pushing out of view the contrary ; a spurious attempt to evade as long as possible a primal cause, which, in the event, has to be admitted after all. Similarity of structure by no means declares, of necessity, corporeal unity of origin or of descent, and analogy of function indicates comprehensive design.

Evolution is the unfolding of a glorious plan, with uniform and progressive gradation, which by no means sets bounds to the creative ability. The mere fact of periodic phenomena within and around us proves a parallelism,—a similar working of the same great mind, and not their interdependence. The denunciation, "*not scientific*," is neither demonstration nor confutation.

Admitting the influence of seasonal changes upon us, this only signifies that a part of the economy *responds* to stimulus from without, but does not show that this stimulus originates the power or method of response. Such influence is almost a directing agency, from which the capability of response is well defined, and I care not whether you consider it an endowment of our present system, or trace backwards to the *Amœba*, or to the ultimate forces of nature, the original atom must have at some time, somewhere, implanted in it this power of action, and of rhythmic action, which is, therefore, of original impress. We must clearly distinguish,—(1) a capability, (2) its provocative, (3) its additional and peculiar quality of rhythmic performance.

All of our functions may be said to be periodic. This is based upon the indestructibility of matter ; it is really an outcome of its molecular solubility. Every function must have its period of rest and activity,—a tribute to our fallen nature. Each part to do its duty well must have its time for repose, without which it would soon become exhausted, the vital bond dissolved, and death ensue. This is the beginning and cause of periodicity.

It is, then, a natural endowment, a gift to the body, and not a faculty acquired from without, and is shared in common with the universe of matter around us, and is an evidence of temporary existence. "And there shall be no night there ; and they need no candle, neither light of the sun ; for the Lord God giveth them light" (Rev. xxii. 5), is a prophecy not only that we shall put on immortality, but that there shall be a cessation of periodic phenomena and a persistence of cosmic facts unknown to our sphere.

I would not, moreover, have you forget that many of our functional periods are the result not of original bent but of habit. That acts frequently repeated may become periodic, and many of our bodily needs with fixed intervals of expression, may be affirmed to be nothing more than the results of glandular sensations,—mere assertions of an educated reflex, and hence dependent upon intrinsic causes and conditions. Thus, the feeling of hunger recurring at certain hours is probably subordinate to the reflection of the glands of the stomach, which passes away as they are relieved of their secretions. Certain irritative dyspepsias are accompanied by a feeling of hunger directly after a meal, due, I dare say, to the presence of food causing abnormal irritation and congestion of the follicles, in like manner as the sexual excitement dependent upon the distention of the seminal vesicles and possibly of seminiferous tubules is dissipated by ejaculation, while excessive venery, by inducing irritation, retroactively evolves a constant, though weakened, desire.

We sometimes meet with those curious instances of periodic abortion, in which (ignoring for the moment structural defects, which prevent the uterus attaining more than a limited bulk) the patient, otherwise healthy, throws off the product of successive pregnancies at a uniform term,—only obviated by placing the pregnant woman in bed until past the fatal period.

These and other illustrations which might be adduced show that our habits may be

evolved within us directly contrary to custom or to the influences supposed to be acting from without. There is, therefore, a part of the economy which, under proper training, can regulate and develop rhythmic effects.

The most marked physiological rhythm is found in the respiratory and cardiac cycle.

The respiratory centres are in the medulla at the level of gray matter of the fourth ventricle (the vital knot), placed on either side of the point of the calamus scriptorius, and connected by a gray commissure near the motor nerves of the tongue and lips, and cardiac filaments of the spinal and pneumogastric nerves, so that in labio-glosso-laryngeal paralysis the tongue is generally first affected, then the palate, then the orbicularis oris, followed by syncope and suffocation (Duchenne).

The centripetal paths of respiration are the pneumogastric and the numerous sensory nerves of the skin. The centrifugal, the motor nerves from the cervical and dorsal regions of the spinal cord to the diaphragm and the walls of the thorax. Cut the pneumogastrics, respiration will continue. Divide the spinal cord below the medulla, the facial and laryngeal movements will continue, the nostrils still dilate, the soft palate is swayed by the respiratory current, with a rhythmic widening and narrowing of the glottis. Moreover, the whole of the encephalon may be removed from above, and the spinal cord, as far as the origin of the phrenic cord, from below, without suspending the most essential of the respiratory centres. Now division of the cranial nerves in no way destroys respiration, but the destruction of these centres, as shown by experiment and in disease as above, causes its immediate cessation. Hence it is clear that the respiratory impulses proceeding from the respiratory centres are not simply reflex, but evidently start *de novo* from the centre itself. The centre is automatic and not simply reflex (Foster, Carpenter, Küss, Powers).

The heart of a frog, turtle, or fish will beat for hours, or under favorable circumstances for days, after removal from the body. The beat goes on even after the cavities have been cleared of blood. Küss states that the heart of an executed criminal continued its rhythmic contractions an hour after death.

There have been found in the heart itself three principal ganglia,—the ganglion of Remak, near the opening of the inferior vena cava; the ganglion of Ludwig, in the interauricular septum; the ganglion of Bidder, in the left auriculo-ventricular septum. The ganglion of Ludwig paralyzes, the others

cause movements. The heart of the tortoise being cut into two pieces, in the one comprising the auricles and base of the ventricle rhythmic movements were found to continue, but not in the residue.

The rhythmic pulsatile movements of the heart are visible in the course of the second day of incubation in the fowl, and before any differentiation of tissue can be observed (Powers). The "rudiment of the mammalian heart, which is the earliest of the permanent organs of the embryo that comes into functional activity, consists of an aggregation of cells forming a thickening of the mesoblast beneath the anterior portion of the intestinal canal, and lying in the general pleuro-peritoneal cavity. . . . For a long time after it has distinctly commenced pulsating, and is obviously exerting a contractile force, its walls retain the cellular character, and only become muscular by a progressive histological transformation" (Carpenter).

Brown-Séguard found rhythmic movements of the diaphragm in rabbits after section of the phrenic nerve, and even after destruction of the entire spinal cord. He attributes them to minute ganglia, described by Rouget, on (terminal?) filaments of the phrenic nerve.

Peristaltic movements "may occur in a piece of intestine cut out from the body wholly independently of the central nervous system." "The only nervous elements which can be regarded as essential to their development are the ganglia of Auerbach, or those of Meissner in the intestinal walls" (Foster's "Physiology," p. 228).

Thus far we conclude—

That periodicity is a physiological quality inherent in the body, and existing as an original endowment in the healthy nervous system; that certain ganglia have been demonstrated as in themselves giving out rhythmic impulses, being alone able to evolve these *de novo*, and exercising this function "before any differentiation of tissue can be observed," and certain intrinsic actions, at first irregular, when repeated may become recurrent at stated hours through an educated reflex,—that is, by development of the central or ganglionic nervous system.

Intermittence is a peculiarity of many pathological conditions. Trousseau tells us "the intermittent or remittent type testifies to the existence of the nervous element. Diseases of nervous type often have periodicity, as epilepsy, catalepsy, chorea, many neuralgias, etc., these being manifestations of existing disease. Marsh fever is diathetic, like

gout, syphilis, etc., in that it tends to return at stated periods. Solar neuralgias occur in perfectly salubrious countries, where neuralgia comes on in the morning and goes off at night." A patient with "exophthalmic goitre every summer is seized with fever again or has a persistent cough, but auscultation detects no organic lesion of the lungs."

Professor Agnew, in discussing suppuration, says, "The pain is sometimes periodical, as in disease of the bones or joints, coming on in the evening and continuing for several hours;" and, again, "rigors in deep abscesses may return at regular periods with the uniformity of an intermittent."

Murchison, in an interesting sketch of intermitting or paroxysmal pyrexias and their differential characters (*Lancet*, May 3-10, 1879), enumerates twelve varieties:

1, Malarious ague; 2, enteric fever; 3, relapsing fever; 4, pyæmia; 5, pent-up pus; 6, ulcerative endocarditis; 7, tubercular fever; 8, lymphadenoma; 9, syphilitic fever; 10, urinary intermitting fever; 11, hepatic intermitting fever; 12, morphine habit.

A few of his cases are worthy of brief mention.

Thus, "In typhoid fever, for ten to fourteen days, a patient may present all the usual symptoms, . . . at the end of that time the attacks seem to abort; the pyrexia at first becomes more and more remittent, and then intermits. For a week longer the morning temperature may be normal, or possibly at length subnormal. . . . But in the afternoon, or towards evening, the temperature rises daily to 103° , 102° , 101° ; the patient becomes flushed and restless, and often in the night may perspire profusely. . . . Should the patient be seen for the first time during this stage, his case might be mistaken for one of malarious ague."

Again, "I have repeatedly known cases looked upon and treated as malarious ague when the real cause of the intermittent fever has been pyæmia, and the error is all the more likely to be committed from the fact that large doses of quinine, although they will not arrest, will sometimes postpone the paroxysms of fever."

Again, "Fever in tuberculosis, many weeks before any local signs of tubercle can be discovered, . . . may be due to the deposit of tubercle in the lymphatic glands, to the development of an active process in obsolete caseous deposits or to deposit of miliary granules, which in no ways alter the normal physiological signs."

Again, "Syphilitic fever of intermittent type may occur,—1. In common with development of the eruption and *first* appearance of constitutional symptoms. 2. In common with syphilitic periostitis and rheumatism."

Again, "Passing a catheter may cause signs of nervous origin, but fever of intermittent type may be a result of stricture of the urethra, or from any cause of obstruction of the urinary passages, as enlarged prostate, calculus in ureter, the pressure of new growth upon the ureter. The fever may take an algid type, and may be due to absorption of some septic material produced in the decomposition of urine behind the seat of obstruction."

Again, "Patients with gallstones blocking the bile-ducts, the common hepatic or cystic ducts, are very liable to paroxysms of fever which simulate ague. Quinine seems to postpone the attacks."

Dr. Ord ("St. Thomas' Hospital Reports," vol. xi. p. 36): "A gentleman, æt. 30, who had never been in the tropics, suffered from daily attacks of high temperature, with shivering and sweating. . . . He was sallow, worn, emaciated, with some enlargement of liver, none of spleen, . . . with marked evidence of severe primary and a history of secondary syphilis. . . . Took quinine in large doses, and fever was much reduced, but only for a short time. 30 grains ioidid. potass. daily was given, and after two days of this treatment temperature fell and the rigors ceased."

J. Wickham Legg ("St. Bartholomew's Hospital Reports," vol. x. p. 71): "Paroxysmal hæmaturia is a disease characterized by the sudden appearance in the urine of a certain amount of blood or of its chemical constituents, attended by general symptoms which closely resemble those of a fit of the ague."

Dr. J. H. Musser, of this city, in an instructive monograph on "Paroxysmal Fever now Malarial" ("Proceedings County Medical Society," 1884), reports a patient with such marked symptoms that empyema was suspected, and doubt only removed by paracentesis, proving the effusion was serous.

In another case the early formation of meningeal tubercle simulated malaria in its symptoms, and was treated as such, the true character of the disease only being discovered in the fourth week, seventy-two hours before death.

In another case primary cancer of the gall-bladder was thought to be malarial almost until death.

A patient who came under my care several

years ago had frequent, and at times somewhat profuse, hemorrhages from the bladder, attended by most alarming rigors, with heat and sweating. At times during the chill he would go into a state of collapse, so that it would seem as if he must succumb. There were some suprapubic tendencies. The case was a very obscure one, and a variety of opinions had been given the gentleman as to the cause of the symptoms, among which were hemorrhage from the kidney, possibly malignant, paroxysmal hæmaturia, hemorrhage from stricture of the urethra, etc. By a process of rigid exclusion I managed to locate the trouble in the bladder. Quinine seemed to do good, and washing out the bladder with a double catheter and a solution of boracic acid relieved the pain and vesical irritation, the urethra having been previously dilated to normal by metal bougies. The doubt as to diagnosis was removed in about a year, as, after a long watching, the patient passed with the urine masses which proved under the microscope to be polypoid. In the fall I went out of town for a couple of weeks, and the patient continued the washing out of the bladder himself, and found one day he brought away some of these masses in the eye of the catheter. He reintroduced it and withdrew others, and so continued from time to time till no more came, after which the bleeding stopped, the rigors ceased, and his health and body-weight were much improved. This is now some three years since, and only a few times, and that more especially of late, have there been traces of blood from the passage, with no reappearance of the other symptoms. I could multiply instances, but think we already have sufficient evidence to establish the assertion that intermittence is a concomitant of many diseased conditions.

I have endeavored to show that periodicity is a property of the healthy nervous system. It is therefore merely a healthy phenomenon reproduced in disease. We should not regard it as a symptom, but merely as an epiphenomenon.

We think this explanation far more rational than many other of the clumsy theories in vogue. Thus, Billroth declares, "The paroxysms of fever in pyæmia have a similar origin to those of ague, formed perhaps from decomposing pus being poured from time to time into the blood, *under favorable circumstances* exciting rigors and fevers."

Murchison asserts, "The fever paroxysms are due to propulsion by fits and starts of products of disease from the spleen."

Just as there is a fixed law as to time of birth, of puberty, cessation of menses, and of the cardiac and respiratory cycles, all of which are dependent upon the primary rhythmic endowment of the nervous system, so the action of the *materies morbi* will produce each its own series of symptoms, which may each or all of them be paroxysmal in their manifestation. Of the practical side of my subject I will only speak briefly, as I have already trespassed too far upon your time. We have too long considered chill, fever, sweat, or the recurrence of any one or all of these at regular intervals, as characteristic of ague. We were taught to *always* remember that malarial poisoning might be engrafted upon the onset of other distinct diseases. That malarial poisoning might induce the most grave and obscure symptoms.

I remember well Dr. Wood enforcing this by relating a case of epileptoid convulsions which he regarded as a result of malaria which was, indeed, cured by quinine.

Whilst not denying the virulent and insidious nature of paludal poison, I think we should regard the other side closely, that the rhythmic display may be produced otherwise than by this.

How many of our phthisical patients are treated as malarial, yes, even in the stage of cavity-formation, because the physician was misled by the regular recurrence of certain symptoms! One patient with hectic, loss of flesh, and rigors was declared to have phthisis, when he was suffering from syphilis, with suppuration of inguinal glands. The rigors and fever disappeared under the use of a bistoury.

I have purposely avoided the allied subjects of the mechanism of fever and chill, the rationale of motor impulse, or of peripheral irritation, and the differentiation of diseases, but allow me in closing to inculcate the maxim, Never say your patient has *malaria* or *ague* until you are *sure* he has *nothing else*.

It has been my privilege to endeavor to maintain,—

1. Periodicity is a physiological quality inherent in the healthy body, and more particularly in the ganglionic nervous system.
2. It is modified but not produced by influences external to the body.
3. Intermittence in disease is but a manifestation of a normal function under morbid excitation, and should not be considered a pathognomonic symptom of any class of diseases, much less of any special poison.

4. Intermittence is a symptom attendant upon many diseases.

5. By clearly recognizing the intra-nervous origin, subject, however, to irritation and excitation by extrinsic stimuli, we eliminate one of the most fruitful sources of serious error in diagnosis.

1523 GREEN STREET.

RECOVERY FROM FOUR-FIFTHS OF A GRAIN OF HYOSCINE.

By W. H. H. GITHENS, M.D.

MISS L. S., about 45 years of age, dress-maker, light complexion, medium stature, and of fair physical development, sent for me November 28, 1885, on account of menstrual suppression; this was followed by ovarian neuralgia. Typhoid fever of a mild type gradually developed, and my visits continued through December, 1885, and up to the 12th of January, 1886, when I discharged myself, my patient being able to go out for a short walk. There had been a good bit of delirium through the fever, but the mind seemed to clear up entirely during the convalescence. There was not a perfect return to strength, and the disposition was not precisely what it had been before the fever. In March, 1886, I was called to see her again on account of sleeplessness, and prescribed hyoscine hydrobromate (Merck's), gr. i; alcohol, f3i; aqua, f3iv. M. Sig.—Four drops at bedtime for sleeplessness. Thus giving about $\frac{1}{8}$ grain at a dose. One or two doses usually accomplished the desired purpose. After a few days the insomnia passed away, and the bottle was put aside, less than a fluidrachm having been used. A few days later, while she was alone, she drank all that remained in the bottle, not less than four-fifths of a grain of hyoscine hydrobromate (granting that the prescription had been properly filled). Profound sleep was the only effect of this enormous dose. A neighboring physician was called in; he used towel-slappings and other forms of personal violence, and administered croton oil. I did not see the patient until the next day, when all effects of the hyoscine had passed away, so I can tell nothing of the state of the pupils or skin. The latter was bruised from the violence, and her mouth, tongue, pharynx, and stomach were in a terrible state of inflammation from the local action of the croton oil. I do not know why it was administered.

She committed suicide by hanging, July 27, 1886. Her mania took the form of fear of personal injury by men, the first objects of dread being workmen repairing the street-railway and men in a blacksmith-shop across the way. Removal to another house and mental occupation did not have any good effect: her room became peopled with the phantasms of her brain.

A FEW WORDS ON A CERTAIN KIND OF INSOMNIA.

By F. EKLUND, M.D., STOCKHOLM, SWEDEN.

THE two most reliable signs of perfect health are, firstly, absence of pain; and, secondly, the ability of sleeping tranquilly and soundly.

But, unfortunately, the above state is comparatively rare, as the actual number of those who are victims of this most trying and serious affection—insomnia—is very great, and, moreover, is still on the increase.

As it would be beyond me to enter into a minute or exhaustive treatise on the subject, I must content myself with giving the reader a short account of a certain kind of insomnia which is most frequently met with, and which at the same time is most difficult to treat. I refer especially to the insomnia caused by malaria.

Guided by the experience of many years, I will, in as few words as possible, jot down the results of my observations concerning the different symptoms and forms of the malady. Serious mistakes may result if the cause of any insomnia be either mistaken or unknown.

First, we have a group of patients who sleep neither day nor night. It seems an utter impossibility for them to close their eyes or rest for a moment. All during the long night-watches they lie wide awake and count each stroke of the clock, and are painfully conscious of every sound. They are tortured by their own thoughts, and arise in the morning tired out instead of refreshed, scarcely able to get about, and almost entirely unfit to attend to their daily duties. During the day they sometimes feel overpowered by sleep, but when night comes again it is only a repetition of the previous one, and again the morning dawns without the patients having enjoyed a moment's sleep.

In another form of this complaint, when the patients have once awakened they find it

utterly impossible to get to sleep again, after, perhaps, a rest of only two or three hours at the very longest. Nevertheless, they will feel strengthened and refreshed by this short sleep sufficiently to be able to attend to their business, during which, however, they frequently break down, overcome by fatigue, their limbs seeming to give way under them.

To a third class of insomnia belong those patients who are able to sleep well upon retiring, but who always wake up at a certain time or moment. If it be on the hour, they will always start up out of their slumber while the clock is still striking, and after that there is no sleep for them for the rest of the night. When they awake they state that their short rest seems to have perfectly refreshed them, but they are usually subject to slight chills and fever and sweating, also to neuralgia and lumbago, and frequently to exhaustion.

It is most frequent upon careful examination of such patients to find that they for some time past have been suffering from intermittent fever, and are thus under the continued influence of malaria, and intermission is always more or less evident.

It is my intention to endeavor to give a natural and plausible explanation of the cause of this peculiar insomnia, and it will be hardly necessary for me to add that my conclusions are not based on hypothesis, but on practical experience.

It is a well-known fact that certain alkaloids, such as caffeine, theine, and theobromine, have the property of causing wakefulness.

It seems very probable to me that the microbes of malaria might produce a similar pathological action in many respects to that caused by the above-mentioned alkaloids. It is evident that these microbes are contained in great quantities in the veins, and also in the smaller vessels of the pia mater and the large ganglions of the brain. Here they may act as a most delicate "reagent," by means of which the existence of malaria may be proved,—viz., by their effect in producing insomnia of the patient.

Regarding the treatment of such malaria I have invariably obtained the best results by using quinine.

The treatment generally restores sleep to the patient in a very short time. The following is the formula I mostly use :

R Quin. sulph., .40 to 1 grm. (6 to 15 gr.);
Sod. bicarb., 1 to 2 grm. (15 to 30 gr.). M.
S.—F. tal. dos. No. xii. ad caps. amyl.

Take 1 powder or capsule every morning, and, if the case require it, 1 in the evening.

I found this formula to be most useful. I used the sodium bicarbonate because in most cases the patients were greatly troubled by symptoms of chronic gastric catarrh, which was relieved by its use. In some special cases I found quinine combined with dilute phosphoric acid to be of great value, in the following formula :

R Quin. sulph., 4 grm. (60 gr.);
Acid. phosphor. dilut., 5 grm. (75 gr.);
Syrup. zinzib., 30 grm.;
Aq. dest., 120 grm. M.
S.—A tablespoonful twice a day.

It will perhaps be unnecessary for me to state that I am bitterly opposed to the use of morphine, chloral, or any other narcotic or soporific in such cases. All my honored colleagues agree with me as to the danger of the use of such drugs in this affection. Instead of doing good, they augment and heighten the disease more than the microbes themselves do. In connection with this comes also an overwhelming sensation of excessive fatigue and mental depression, accompanied frequently by increased sexual desires and a morbid anxiety about business, etc.

I have furthermore found a hydropathic treatment to be of great service in the treatment of such insomnia, and usually administer a hip-bath twice daily. The temperature of the water should be from 28° to 32° C., and the patient should remain in the bath for two to four minutes. The water should cover the navel. It may be necessary for the patient to take a course of forty or fifty such baths during treatment. After the bath the body and limbs should be washed and then well rubbed. A bucket of cooler water (say 18° to 20° C.) may be poured over each shoulder, and later, after ten such baths have been taken, the patient should take a cold shower (10° to 15° C.) for about twenty seconds or a minute, and should then be well dried and rubbed. A massage treatment has also good effects.

In advanced stages of the malady friction should be used with a bath-towel dipped in tepid, fresh, or even cold water, as soon as the patient has gotten up.

As for my personal experience, I have spent many days and nights in the marshes; indeed, for the last eight years have lived and practised in a marshy country, and have found the above treatment to be most invaluable both in treating my patients and myself.

Leading Articles.

CHRONIC LEAD-POISONING.

MOST of our readers are no doubt aware that some little time since Dr. J. J. Putnam, of Boston, called attention to the fact that in many cases of obscure diseases of the nervous system the symptoms are due to lead-poisoning, although there is no blue line upon the gums. In regard to the general correctness of these observations there seems to be little doubt. But we suppose few persons are prepared for the disclosures made in a recent paper by Dr. Putnam ("Transactions Association of American Physicians," 1887). In this paper there are reported eighty-six cases, in none of which were the classical symptoms of lead-poisoning, such as colic, marked cachexia, characteristic cerebral attacks or paralysis, or blue line on the gums, and yet in forty-eight of which lead was found in the urine. The various symptoms which were present in the cases in which lead was found are summed up by Professor Putnam as follows:

1. Paræsthesia of the hands and feet (two middle toes); twitching of the fingers; exaggeration of the knee-jerk, especially left.

2. General feebleness; paræsthesia in legs, with slight anæsthesia; twitching of muscles of legs; marked improvement under treatment; malarial history.

3. Spastic paraplegia; cramps and twitching of the calves; knee-jerk and ankle clonus exaggerated.

4. Trembling of hands; sense of coldness and numbness of toes; lancinating pains in legs; fatigue on exertion.

5. Marked progressive spastic paraplegia, with myosis and pupillary reactions; ataxia, and some atrophy of hands.

6. Progressive weakness and stiffness in legs, with diffused and almost universal pains; marked tremor.

7. Temporary pain in chest, with slight dyspnœa; progressive numbness; heaviness and weakness in legs.

8. Numbness in feet and legs, with impairment of strength; tremor of hands and tongue; some wasting of small muscles of the hands; temporary retention of urine.

We are prepared by past experience to believe that multiple neuritis frequently is the result of obscure lead or arsenical poisoning, but confess to some reluctance in acknowledging that so many different forms of nervous and functional disorders are the outcome of one common cause.

The assertion of a chemist that he has found lead in the urine is not absolute proof that the lead really existed in the urine, nor is the existence of lead in the urine absolute proof that the symptoms of disease present in the case are the result of lead-poisoning. This thought naturally leads to two questions: First, Is the method of analysis adopted in the cases of Professor Putnam reliable? Second, May lead be present in the urine of persons free from disease?

The method of analysis adopted by Professor E. S. Wood and his assistants is described by Dr. Putnam as follows (we understand from the context in the words of Professor Wood himself): "The urine is first evaporated to dryness, then fused in a crucible, with the addition of a little pure nitre, till it becomes white. The crucible is then cooled, and dilute HCl added, hot, to extract the residue after ignition. It is then filtered, and the filtrate treated with ammonia to alkaline reaction, to precipitate the phosphates and iron. Sulphide of ammonium is added at the same time, which throws down the sulphide of iron and lead. This is washed three times by decantation with hot water, then water is added, and the whole acidified with

HCl, and allowed to stand until the next day. It is then filtered through a small filter and the residue washed. A little pure (free from iron) nitric acid is then added, drop by drop, by which the sulphide of lead, if present, is dissolved and carried through as nitrate of lead. This is collected in a watch-glass, evaporated to dryness, and the final test made by the addition of a drop of water and a crystal of iodide of potassium."

In a matter like the present it is of the gravest importance that the method of analysis employed by the chemist be correct in all the principles and details. We therefore submitted the above statement to a chemist of authority for criticism. The first point to which he directed attention is that many crucibles contain lead in their glaze, which lead certainly would yield to a heated mixture of organic matter and pure nitre and form a soluble plumbite of lead. A large manufacturer of crucibles at Trenton informs us that many of the glazes contain as much as thirty per cent. of oxide of lead. That the glaze of all crucibles does not contain oxide of lead was established by our chemist by actual testing. Whether Professor Wood's crucibles contained lead or not remains at this distance an uncertain question. The second criticism is as to the meaning of the word "pure." When a "little pure"—*i.e.*, a little concentrated—nitric acid is added to sulphide of lead it does not, as stated in the text of Professor Putnam, dissolve all of the lead as a nitrate, but converts a portion of the sulphide into sulphate, which is insoluble and remains on the filter. There must be, therefore, if the method of Professor Wood be strictly followed out, a loss of lead at this point. Probably Professor Wood used nitric acid which is not concentrated, and which does not convert the sulphide into the sulphate, but the word *pure* ought to have been more definitely explained than it is in the text. A third very important point is the failure of Professor E. S. Wood to state, in the last line of the description of his method, whether he relied upon the formation of a yellowish color, or whether he actually got the crystalline plates of iodide of lead. If he relied upon the color his results are open to error, because if a little nitric acid had been left in the evaporation the yellow color would have been produced by the liberation of a minute quantity of iodine. Or, again, the yellow coloration may have been produced by the action of the potassium iodide upon a trace of copper, which latter may have got into the solution from

the use, or even the contiguity, of brass or copper utensils during the course of the analysis. This is of very frequent occurrence in laboratory operations, and is often due to minute particles of cupric oxide carried by currents of heated air and falling into the material under examination. So, again, the hydrochloric acid may not have completely dissolved the iron from the precipitate of the sulphides of lead and iron, and the result of the final test with potassium iodide (if simply a coloration) may have been due to the presence of iron. In order to avoid these fallacies, the final residue should at least have been tested for copper and iron. Finally, a serious possible source of error in the analysis of urine made according to Professor Wood's method is, that if the urine contain any bismuth it would yield not only the yellow color in the final test, but also a precipitate of yellow crystalline plates scarcely distinguishable by the eye from those of iodide of lead.

In regard to the possible contamination of lead in the bottles in which the urine was collected, Professor Putnam probably secured himself against it sufficiently by acidifying the urine, although, strangely enough, he is in error in the belief that flint-glass, out of which his bottles were made, is free from lead. Flint-glass is lead-glass.

The second question was asked a few paragraphs back as to how far lead may be tolerated in the system of human beings without causing disease. There seem to us only two methods which offer any hope of arriving at the solution of this problem. The first of these methods consists in the making of numerous examinations of the urine of persons who are entirely healthy. If lead be found to be habitually present in the urine of even a small proportion of apparently healthy persons, its presence in any given urine loses much of its significance and we must concede that a very considerable amount of lead must be accumulated in the system in order for it to act as a distinctly toxic agent. Unfortunately, in the series of analyses made at Harvard the urine was examined chiefly of persons more or less out of health, and therefore we are unable to draw any distinct conclusions as to the tolerance of lead by the human system, although Professor Putnam records having found it in the urine of three absolutely healthy individuals. We sincerely hope that some one will undertake a series of analyses looking for lead in urine during health. The second method of testing the relation between

lead in the urine and symptoms is the therapeutic one : if in such cases the symptoms disappear under the administration of iodide of potassium and the other usual treatment of lead-poisoning, it is fairly made out that the symptoms are due to the lead. Failure of improvement, on the other hand, does not prove the lack of connection between the metal and the symptoms, because the metal may already have produced serious organic disease which is irreparable, although the metal itself be entirely removed from the body.

STROPHANTHUS.

THIS new African heart-drug continues to attract attention both abroad and in this country, and the evidence seems to be sufficient to show that it has great practical value.

Professor Drasche (*Wien. Med. Blätter*, 1887, page 586) found 5 drops of the tincture of strophanthus given to the healthy man would produce in about three hours a fall of from about 8 to 12 beats per minute of the pulse, which would last part of the day. After 10 drops the pulse fell in half an hour 12 to 20 beats ; after 20 drops the pulse sank in the single case given from 84 to 54 strokes. There was no influence on the respiration, but a lowering of the temperature, in some cases as much as a degree. Fifteen drops given hypodermically caused great irritation and pain and swelling at the place of injection, violent headache, repeated vomiting and nausea, and copious secretion of urine : the pulse fell in an hour from 96 to 84, and the next day the headache and general ill feeling continued, with a very pronounced local irritation. In a strong forty-five-year-old man suffering from left-sided pneumonia, four doses a day of 5 drops of tincture of strophanthus was followed in twenty-four hours by a fall of the pulse 18 beats per minute, and by a distinct slowing of the respiration and reduction of the temperature 0.8° C. The pneumonia itself was not affected, and the crisis came on the ninth day. In another similar case, under the influence of the strophanthus, the pulse fell from 128 to 88 beats. In acute phthisis the remedy acted very promptly : there was high fever, and the pulse ranging from 140 to 152 ; five minutes after the exhibition of 10 drops the pulse fell 20 beats, and two hours later 40 beats, whilst the temperature had gone down between one and two degrees, and the distress-

ing cardiac palpitation was relieved. The rapidity of the action of strophanthus showed itself also in a case of gastro-duodenal icterus. In twenty minutes after the use of 20 drops the pulse had fallen from 72 to 60, and the blood-pressure, as measured in a temporal artery, had increased ten per cent. According to Professor Drasche, 40 to 50 drops a day must be considered as the maximum dose of the tincture. Under 60 drops a day, in an experimental case, the pulse became exceedingly small, weak, and irregular. In a case of vaso-motor neurasthenia, with great rapidity of the pulse, the continued use of the medicine was kept up, with interruptions, until six hundred drops of the tincture had been taken, without the production of any evidences of cumulative action. Professor Drasche has also used the remedy in a number of cases of heart-disease. In one case of a thirty-six-year-old patient with fatty heart and very pronounced cardiac symptoms, 10 drops of strophanthus tincture produced great relief of palpitations and of the dyspnoea. One hundred and sixty drops were taken in the course of five days without the slightest evil influence. In a second very advanced case, in which there was dropsy, very pronounced dyspnoea, and very irregular pulse (120), and in which digitalis had failed, 5 drops of the tincture every two hours, until thirty drops had been taken, caused the pulse to fall to 108 without becoming more regular, but shortly afterwards the patient fell into a stupor, and four days later died. In another similar case, forty drops of the tincture a day was followed by marked fall of the pulse and increase of the urine. Strophanthin was later given in solution, the four doses each day amounting to two milligrammes. The pulse became very irregular, varying from 36 to 60 beats every minute. There was marked increase in urinary secretion and great lessening of the dyspnoea. In a case of aortic insufficiency, which came into the hospital almost moribund, with the pulse 96, scarcely to be felt, 15 drops in an hour caused the pulse to fall to 72 and become much stronger, and the patient slept through the night, for the first time in three months. Afterwards 40 drops of strophanthus tincture being given daily, the pulse fell to 60 ; but the patient complained of so much burning in the œsophagus and stomach and nausea that the medicine was withdrawn and digitalis substituted. It, however, failed to have influence, and the man shortly afterwards died suddenly. In a second case of

aortic insufficiency, the tincture of strophanthus was given for four weeks regularly, 40 drops a day, with great relief to the dyspnœa. Besides these cases, Dr. Drasche reports several others in which the strophanthus tincture produced results similar to those that have been just described. The effect upon the excretion of urine seems to have been most extraordinary. In some instances the amount excreted after the administration of the drug was five, or even six, times what it had been before. Almost universally when the strophanthus was pushed the patient complained of burning in the œsophagus and stomach, with loss of appetite and extreme gastric distress, which not rarely rose to vomiting; sometimes there was diarrhœa. In no case was there any evidence whatever of cumulative action. The action of the drug is not only more prompt in coming on, but is evidently less permanent than is that of digitalis. Dr. Drasche also tried using the remedy in cases of mitral insufficiency; here the effect of the remedy was often more marked than in cases of aortic disease. In one old case, with bloody sputum and other very severe symptoms, 25 drops a day of the strophanthus tincture had so favorable a result that on the eighth day the patient left the hospital. In a case of mitral stenosis, with very severe symptoms and great cyanosis, after a second dose of 45 drops of the tincture the pulse fell from 88 to 44 per minute and the respiration from 36 to 18, the dyspnœa disappeared, and the heart's action became not only stronger but less irregular. Under the continued use of the remedy the pulse became strong, at the rate of 44 beats, the respiration 16, and the urine enormously increased. This patient took in all three hundred and sixty drops of the tincture without any untoward symptoms, but with the most favorable results, the patient leaving the hospital greatly relieved. Other cases of mitral disease were affected similarly. As the result of his observations, Professor Drasche thinks that whilst we must consider digitalis to act more as a tonic agent upon the heart, strophanthus must be looked upon rather as a cardiac stimulant. He is also particular in cautioning a physician to see that the preparation used is genuine and pure. Strophanthin he believes to fully represent the tincture. As a diuretic, he gives the daily dose of strophanthin as 3 milligrammes, and, for reasons which we have already laid before our readers, condemns its use hypodermically.

Mr. Zerner and Loew (*Wien. Med. Wochenschr.*, Nos. 36 to 40, 1887) have recorded the results obtained in the service of Professor Bamberger, of Vienna, in using strophanthus in cardiac affections. They affirm that it is equal in efficacy to digitalis, and that they have only seen it fail when the degeneration of the heart-muscle has gone to the last degree. The indications and contraindications for its use, they think, are identical with those controlling the employment of digitalis. In one mild case of Basedow's disease, the pulse, which, at the moment of administration, was 100, half an hour later had fallen to 88; half an hour after this it was 84, but four hours later it had regained its original frequency. In seven out of eleven cases of Bright's disease they achieved very good results from its administration. It is especially indicated when there are evidences of secondary failure of the heart in renal disease. In several healthy subjects no diuretic action at all followed the use of strophanthus. This, if it be confirmed, proves that the diuretic action of the drug in disease is dependent not upon any influence upon the secreting structure of the kidney, but is the result of the increased blood-supply to the organ. Zerner and Loew also confirm the statements of Drasche that in large doses the remedy produces nausea and vomiting.

Dr. William Budd reports in the *Lancet*, September 10, 1887, two cases of mitral cardiac disease, with albuminuria, and excessive and other very severe symptoms, in which strophanthus was entirely successful after the failure of digitalis. The effect of the drug upon the secretion of the urine was extraordinary. He used 5 minims of the tincture three times a day.

A new use for this remedy, which more than its properties as a cardiac tonic will serve to render it popular, is its employment as a diuretic in renal colic. Dr. Hutchinson reports, in the *Provincial Medical Journal*, October 1, 1887, a case of marked uric acid diathesis occurring in a man aged 52, who, since twenty years of age, had been subject to periodical attacks of gravel. When Dr. Hutchinson was called to see the case, the patient was then suffering from a violent attack of colic from the passage of a calculus through the ureter. There were severe lumbar pains, scanty urine, and difficulty in micturition. At the onset of the attack the urine was high-colored, and then smoky, and finally contained blood. The bowels were confined; there was no nausea, but total

anorexia. Dr. Hutchinson ordered him turpentine stupes across the loins, plenty of fluid to drink, a seidlitz powder in the morning, and tincture of strophanthus in 5-minim doses three times a day. The result of this treatment was to produce copious diuresis and a rapid relief of the pain.

In the absence of any official standard, the tincture of strophanthus, as sold in various drug-stores, must vary in strength, and the important question as to the proper dose to be employed must remain unsettled. The only recourse that the practitioner has, who does not know exactly the method in which the tincture that he is using has been prepared, is to commence with a minimum dose, and increase until the effects are obtained. The tincture should be prepared according to the method of Professor Fraser, as given in the first volume of the *British Medical Journal* for this year. The dose of this tincture may be set down as 5 drops, carefully increased, if necessary.

DIURETIC ACTION OF CAFFEIN.

IN poisoning by caffein there is usually great increase in the secretion of urine, and the statement of Professor Gublin (*Bull. Thérap.*, xci. 523), that the citrate of caffein is one of our most powerful and certain diuretics, has received abundant confirmation. The effect of the drug upon healthy men would indicate that in dropsies it acts not simply by regulating the circulation of the kidney, but has also a distinct effect upon the renal organ itself. That this surmise is correct is proved by the experiments of W. V. Schröder and A. Langgard (*Centralbl. Med. Wissen.*, 1886), who found that when canulas were inserted into the ureters in an animal whose vaso-motor system was completely paralyzed by chloral, injections of caffein into the circulation caused a very great increase in the urinary secretion. Langgard found that usually before the great increase of diuresis the urinary secretion was arrested for several minutes. This is in exact accord with the experiments of Dr. C. D. T. Phillips (International Medical Congress, Washington, 1887), made with Roy's onco-graph. Dr. Phillips found that immediately after the injection of a small dose of caffein, when the blood-pressure was either slightly depressed, elevated, or unaffected, the kidney underwent a very distinct contraction of its volume, which lasted for two, or even three,

minutes, and was accompanied with arrest of the urinary secretion. After the contraction the kidney rapidly expanded beyond its original bulk, and at the same time the urinary secretion became excessive. These various experiments prove that the action of caffein upon the renal secretion is entirely independent of its influence upon the general circulation. The fact discovered by Dr. Phillips does not show, however, that the diuresis is caused by the increase in the flow of the blood to the kidneys. It is much more probable that the condition of the local blood-vessels is the result of the action of the drug upon the renal secreting tissue; especially is this the case, since Schröder found that the division of all the renal nerves did not prevent the increase of the secretion under the action of caffein. Because the secretion from the uninjured kidney was increased much more than from the kidney whose nerves were destroyed, Professor Schröder believes that the drug increases diuresis by acting both upon the nerve-centres and the secreting structure of the kidney. To our thinking, however, the direct injury to the secreting apparatus of the kidney by division of the renal nerves is sufficient to account for the difference between the influence of the alkaloid upon the normal and the operated-upon kidney, without necessitating a belief of the possession by the alkaloid of a twofold influence. Professor Schröder found that there was an increase not only of the liquid, but also of the solid of the urine.

EPHEDRINE, A NEW MYDRIATIC.

PROFESSOR NAGAI has extracted from the *Ephedra vulgaris* Rich., by a process whose details he promises to publish subsequently, an alkaloid to which he has given the name of ephedrine. M. Kinnossuke Miura has published a preliminary note on the action of this drug in the *Berliner Klin. Wochenschrift*, No. 38, 1887, p. 707. He has found that in the frog a toxic dose (of about 8 to 10 milligrammes) of the chlorhydrate of ephedrine produced progressive slowing, and finally arrest of the respiratory movements, without any stage of acceleration. The frequency of the cardiac rate is influenced in the same manner, and the heart is finally arrested in diastole, and the pupil is dilated. These results follow the introduction of the alkaloid in the pericardium or in the lymphatic sacs. In the mammal both

respiration and pulse are considerably accelerated, and finally are entirely arrested, without any previous slowing; at the same time clonic convulsions occur, and the temperature in the rectum becomes elevated. The intravascular blood-pressure is diminished, and then rises above normal during the stage of convulsions, but finally becomes reduced as they pass off. The pupils are dilated whether the poison be injected subcutaneously or instilled in the conjunctival sac. Death is produced by the arrest of the heart and respiration. A lethal dose is .03 to .4 grm. per kilogramme of body-weight in the rabbit, and .22 grm. per kilogramme of body-weight in the dog. In addition to these notes as to the physiological action of the drug the author likewise, under the direction and in the clinic of Professor Scriba, at Berlin, carried out a series of clinical experiments, testing the value of seven and ten per cent. solutions of ephedrine as a mydriatic in normal and diseased eyes. Solutions of six and seven per cent. have proved themselves unreliable in producing dilatation of the pupil, it occurring in some subjects after ten or fifteen minutes from the instillation, while in others it has not appeared. With ten per cent. solutions the author found that the pupils were dilated in from forty to sixty minutes after an instillation of one or two drops, this dilatation being equal on the two sides when no inflammation was present, and when the refracting power of the two eyes was the same. The dilatation of the pupil produced by this drug is not complete, but it was sufficient to permit ready exploration of the retina in all its extent, even although the entrance of the ray of light into the eye caused each time a slight pupillary reaction. Children and aged persons were found more sensitive to the mydriatic action of ephedrine than adults. The accommodation was not paralyzed at all, or at most but slightly. When the iris was in a state of irritation or inflammation, but little dilatation of the pupil was produced by this alkaloid. In normal eyes the dilatation from the time of instillation to the time of the return of the pupil to its normal diameter varied in duration from five to twenty hours. After two weeks of three instillations daily of a ten per cent. solution no conjunctivitis or no disadvantageous result was detectable, and no increase or diminution of the intraocular pressure. Comparative experiments made with solutions of homatropine have demonstrated that following instillations of this mydriatic six to nine hours

are required for the pupil to return to its normal diameter. It would appear from these facts that the chlorhydrate of ephedrine is a convenient mydriatic, which may be substituted for homatropine for the examination of the ocular fundus: it is distinguished from the latter by the facility with which it is prepared, and by the harmlessness of its employment, even although a solution ten times more concentrated must be employed. In addition, its employment is not complicated by any ill effects, and the accommodation is so slightly paralyzed as to cause no inconvenient results to the patient. We will await with interest Professor Nagai's promised communication as to the mode of preparation and chemical constitution of this substance, and for further details as to its clinical employment.

AMYLENE HYDRATE, THE NEW HYPNOTIC.

OUR readers are familiar with the studies of Professor von Mering with amylene hydrate, or tertiary amyl alcohol. At his suggestion this substance has been extensively tested in the clinic of Professor Jolly. Comparing the effects with other hypnotics, such as chloral, paraldehyde, and urethan, the results seem extremely favorable. As reported by Dr. Scharschmidt, in the *Therapeutische Monatshefte* for September, 1887, the drug was administered to eighty patients in one thousand and fifty different doses, given in brandy, with a small amount of syrup of orange-peel to disguise its taste. It was found, however, that this mode of administration was not satisfactory, since the addition of the syrup caused a variable precipitation of the amylene hydrate. The best mode of administration was found to be in combining the amylene hydrate with red wine, and a small amount of sugar added to it. Apparently an equally effective method of administering it is with a small amount of extract of liquorice, which completely disguises the taste of this substance when dissolved in water. The doses in which it was employed in Professor Jolly's clinic varied from 22 to 75 grains, the latter quantity being only once given. The average dose consisted of 45 to 60 grains. Dr. Scharschmidt tabulates the cases in which this drug was employed, from which it appears that in eighty per cent. of his cases sound sleep, of from five to seven hours' duration, was produced with doses varying from

20 to 45 grains. In comparing this with chloral and paraldehyde, its superiority would appear to be very striking, since only in about seventy per cent. of the cases where chloral was used, or seventy-six per cent. in the case of paraldehyde, was the result successful. In the experiments with amylene hydrate no absolute failure was noted in any case, since sleep was always produced either by the continued use of the original dose, or by gradually increasing the quantity. It is noticeable from this that the writer has obtained even more successful results than Von Mering, since Dr. Scharschmidt finds that in general 22 grains of amylene hydrate were equivalent to 75 grains of paraldehyde, and that the action of 15 to 25 grains of chloral was always less favorable than the results which followed the administration of from 35 to 50 grains of amylene hydrate. Absorption of this new hypnotic by the alimentary canal and by the stomach or the rectum occurs with great rapidity, since in many cases sleep occurred within five or ten minutes after the administration of the remedy. In excited or restless cases twenty or thirty minutes were required for the production of sleep, and in maniacal cases from one-half to one hour. No disagreeable after-effects were noted, no disturbance of the appetite or in the action of the bowels, and but rarely slight headache on the following day. Of special importance is the fact that the statement of Von Mering is confirmed, that amylene hydrate produced no modification of the respiratory or circulatory organs. The rhythm and number of the respiratory movements are not to be distinguished from those of normal sleep. No change in the number of the pulsations or in the pulse-curve, as examined by the sphygmograph, were detected after the administration of the amylene hydrate; in some cases a slight increase and in others a slight decrease in the pulse-frequency being scarcely worthy of notice, and presenting no greater variety than might be expected between the sleeping and the waking states. As yet no positive statement can be made as to whether patients become accustomed to this hypnotic and its effects gradually wear off, but it would seem that its having been used constantly with success in two cases for thirty-nine days would warrant a negative answer. Of the eighty cases in which this drug was employed, twelve consisted of melancholia with stupor, five of melancholia agitata, thirteen of dementia paralytica, one of epilepsy with alcoholic dementia, four of primary dementia, seven of

hallucinatory insanity, one of hypochondriacal insanity, one of stupor, one of chronic alcoholism with insomnia, ten of mania, two of delirium, four of delirium acutum, six of delirium tremens, one of hysteria with insomnia and delirium, one of epilepsy with excitement and delirium. It would appear from these results that the tertiary amyl alcohol has proved itself to be a reliable hypnotic, since it can be employed in heart-affections, and is without influence on the alimentary canal. It is superior to urethan, since it produces sleep even in states of the wildest excitement, and is at any rate equally as good as paraldehyde in efficiency, and is free from the disagreeable odor and taste of the latter.

METHYLENE CHLORIDE AS AN ANÆSTHETIC.

SINCE the introduction of chloroform into medical practice as an anæsthetic there has been a constant effort to discover some other anæsthetic which, possessing the advantages, would be free from the dangers of chloroform. The theory that in the various chlorine compounds the danger is in direct proportion to the percentage of chlorine has obtained much support, and it would therefore appear warrantable that methylene chloride (CH_2Cl_2) would be less dangerous than chloroform (CHCl_3). In spite, however, of this theoretical advantage possessed by methylene chloride, it has not been able to displace chloroform, perhaps from the less degree of anæsthetic power possessed by the former. Our readers are already familiar with the recent experiments of Richardson, who, in 1867, first called attention to this substance as an anæsthetic, and with the fact that in spite of the favorable claims advanced by Richardson, with other writers, such as Spencer Wells, the value of this drug is almost universally denied. Dr. Eichholz and Professor Geuther, in a paper published in the *Deutsche Medicinal Zeitung*, August 22, 1887, attributed this doubt as to the value of methylene chloride as a narcotic to the fact that methylene chloride of commerce is not by any means pure methylene chloride, but that the English preparation is a mixture of one part of methylene alcohol and three and four-fifths parts of chloroform, and that the German preparations consist of one part of methylene chloride and four parts of chloroform. This impurity is further testified by the fact that one hundred grammes of

respiration and pulse are considerably accelerated, and finally are entirely arrested, without any previous slowing; at the same time clonic convulsions occur, and the temperature in the rectum becomes elevated. The intravascular blood-pressure is diminished, and then rises above normal during the stage of convulsions, but finally becomes reduced as they pass off. The pupils are dilated whether the poison be injected subcutaneously or instilled in the conjunctival sac. Death is produced by the arrest of the heart and respiration. A lethal dose is .03 to .4 grm. per kilogramme of body-weight in the rabbit, and .22 grm. per kilogramme of body-weight in the dog. In addition to these notes as to the physiological action of the drug the author likewise, under the direction and in the clinic of Professor Scriba, at Berlin, carried out a series of clinical experiments, testing the value of seven and ten per cent. solutions of ephedrine as a mydriatic in normal and diseased eyes. Solutions of six and seven per cent. have proved themselves unreliable in producing dilatation of the pupil, it occurring in some subjects after ten or fifteen minutes from the instillation, while in others it has not appeared. With ten per cent. solutions the author found that the pupils were dilated in from forty to sixty minutes after an instillation of one or two drops, this dilatation being equal on the two sides when no inflammation was present, and when the refracting power of the two eyes was the same. The dilatation of the pupil produced by this drug is not complete, but it was sufficient to permit ready exploration of the retina in all its extent, even although the entrance of the ray of light into the eye caused each time a slight pupillary reaction. Children and aged persons were found more sensitive to the mydriatic action of ephedrine than adults. The accommodation was not paralyzed at all, or at most but slightly. When the iris was in a state of irritation or inflammation, but little dilatation of the pupil was produced by this alkaloid. In normal eyes the dilatation from the time of instillation to the time of the return of the pupil to its normal diameter varied in duration from five to twenty hours. After two weeks of three instillations daily of a ten per cent. solution no conjunctivitis or no disadvantageous result was detectable, and no increase or diminution of the intraocular pressure. Comparative experiments made with solutions of homatropine have demonstrated that following instillations of this mydriatic six to nine hours

are required for the pupil to return to its normal diameter. It would appear from these facts that the chlorhydrate of ephedrine is a convenient mydriatic, which may be substituted for homatropine for the examination of the ocular fundus: it is distinguished from the latter by the facility with which it is prepared, and by the harmlessness of its employment, even although a solution ten times more concentrated must be employed. In addition, its employment is not complicated by any ill effects, and the accommodation is so slightly paralyzed as to cause no inconvenient results to the patient. We will await with interest Professor Nagai's promised communication as to the mode of preparation and chemical constitution of this substance, and for further details as to its clinical employment.

AMYLENE HYDRATE, THE NEW HYPNOTIC.

OUR readers are familiar with the studies of Professor von Mering with amylene hydrate, or tertiary amyl alcohol. At his suggestion this substance has been extensively tested in the clinic of Professor Jolly. Comparing the effects with other hypnotics, such as chloral, paraldehyde, and urethan, the results seem extremely favorable. As reported by Dr. Scharschmidt, in the *Therapeutische Monatshefte* for September, 1887, the drug was administered to eighty patients in one thousand and fifty different doses, given in brandy, with a small amount of syrup of orange-peel to disguise its taste. It was found, however, that this mode of administration was not satisfactory, since the addition of the syrup caused a variable precipitation of the amylene hydrate. The best mode of administration was found to be in combining the amylene hydrate with red wine, and a small amount of sugar added to it. Apparently an equally effective method of administering it is with a small amount of extract of liquorice, which completely disguises the taste of this substance when dissolved in water. The doses in which it was employed in Professor Jolly's clinic varied from 22 to 75 grains, the latter quantity being only once given. The average dose consisted of 45 to 60 grains. Dr. Scharschmidt tabulates the cases in which this drug was employed, from which it appears that in eighty per cent. of his cases sound sleep, of from five to seven hours' duration, was produced with doses varying from

20 to 45 grains. In comparing this with chloral and paraldehyde, its superiority would appear to be very striking, since only in about seventy per cent. of the cases where chloral was used, or seventy-six per cent. in the case of paraldehyde, was the result successful. In the experiments with amylene hydrate no absolute failure was noted in any case, since sleep was always produced either by the continued use of the original dose, or by gradually increasing the quantity. It is noticeable from this that the writer has obtained even more successful results than Von Mering, since Dr. Scharschmidt finds that in general 22 grains of amylene hydrate were equivalent to 75 grains of paraldehyde, and that the action of 15 to 25 grains of chloral was always less favorable than the results which followed the administration of from 35 to 50 grains of amylene hydrate. Absorption of this new hypnotic by the alimentary canal and by the stomach or the rectum occurs with great rapidity, since in many cases sleep occurred within five or ten minutes after the administration of the remedy. In excited or restless cases twenty or thirty minutes were required for the production of sleep, and in maniacal cases from one-half to one hour. No disagreeable after-effects were noted, no disturbance of the appetite or in the action of the bowels, and but rarely slight headache on the following day. Of special importance is the fact that the statement of Von Mering is confirmed, that amylene hydrate produced no modification of the respiratory or circulatory organs. The rhythm and number of the respiratory movements are not to be distinguished from those of normal sleep. No change in the number of the pulsations or in the pulse-curve, as examined by the sphygmograph, were detected after the administration of the amylene hydrate; in some cases a slight increase and in others a slight decrease in the pulse-frequency being scarcely worthy of notice, and presenting no greater variety than might be expected between the sleeping and the waking states. As yet no positive statement can be made as to whether patients become accustomed to this hypnotic and its effects gradually wear off, but it would seem that its having been used constantly with success in two cases for thirty-nine days would warrant a negative answer. Of the eighty cases in which this drug was employed, twelve consisted of melancholia with stupor, five of melancholia agitata, thirteen of dementia paralytica, one of epilepsy with alcoholic dementia, four of primary dementia, seven of

hallucinatory insanity, one of hypochondriacal insanity, one of stupor, one of chronic alcoholism with insomnia, ten of mania, two of delirium, four of delirium acutum, six of delirium tremens, one of hysteria with insomnia and delirium, one of epilepsy with excitement and delirium. It would appear from these results that the tertiary amyl alcohol has proved itself to be a reliable hypnotic, since it can be employed in heart-affections, and is without influence on the alimentary canal. It is superior to urethan, since it produces sleep even in states of the wildest excitement, and is at any rate equally as good as paraldehyde in efficiency, and is free from the disagreeable odor and taste of the latter.

METHYLENE CHLORIDE AS AN ANÆSTHETIC.

SINCE the introduction of chloroform into medical practice as an anæsthetic there has been a constant effort to discover some other anæsthetic which, possessing the advantages, would be free from the dangers of chloroform. The theory that in the various chlorine compounds the danger is in direct proportion to the percentage of chlorine has obtained much support, and it would therefore appear warrantable that methylene chloride (CH_2Cl_2) would be less dangerous than chloroform (CHCl_3). In spite, however, of this theoretical advantage possessed by methylene chloride, it has not been able to displace chloroform, perhaps from the less degree of anæsthetic power possessed by the former. Our readers are already familiar with the recent experiments of Richardson, who, in 1867, first called attention to this substance as an anæsthetic, and with the fact that in spite of the favorable claims advanced by Richardson, with other writers, such as Spencer Wells, the value of this drug is almost universally denied. Dr. Eichholz and Professor Geuther, in a paper published in the *Deutsche Medicinal Zeitung*, August 22, 1887, attributed this doubt as to the value of methylene chloride as a narcotic to the fact that methylene chloride of commerce is not by any means pure methylene chloride, but that the English preparation is a mixture of one part of methylene alcohol and three and four-fifths parts of chloroform, and that the German preparations consist of one part of methylene chloride and four parts of chloroform. This impurity is further testified by the fact that one hundred grammes of

commercial methylene chloride only cost three and a half marks, while one hundred grammes of the chemically pure methylene cost about twenty-five marks. Recently, however, by an improved process of manufacture, pure methylene chloride has been placed on the market at a greatly reduced price. From an elaborate series of experiments Eichholz and Geuther concluded that, whether in its pure condition or mixed with chloroform, methylene chloride possesses great advantages as an anæsthetic, and the authors make the claim that until now the pure article has never been tested as an anæsthetic on man. This is in accord with studies made in the laboratories of the Medical Department of the University of Pennsylvania.

Their experiments in comparing the action of chloroform and pure methylene chloride may be stated in few words, as follows: First, narcosis occurs with both remedies after about the same time. Second, with both drugs there is a preliminary period of excitement. Third, with methylene chloride there is no increase of pulse in the period of excitement; there is in the course of chloroform. Fourth, in both cases after the occurrence of the narcosis there is slowing of the pulse and respiration, though these symptoms occur sooner and to a greater degree in the chloroform narcosis, and the complete arrest of the pulse and respiration occurred much sooner in the case of chloroform than with methylene chloride. The reduction of temperature in narcosis is with both about the same. Methylene chloride produced salivation; chloroform does not; methylene chloride produced transient narrowing of the pupil. In methylene-chloride narcosis the rigidity of the neck is more marked than in the case of chloroform, but convulsions of the limbs are more frequently seen with chloroform than with methylene chloride. With these points of similarity, the only advantage which might be attributed to the methylene chloride is its very much less dangerous action on the heart. For while in chloroform narcosis after the administration of only five cubic centimetres the heart-action is often imperceptible, the authors claim that they have frequently produced profound methylene-chloride narcosis for nearly an hour without ever producing any unfavorable action on the heart. They also state that even when the pulse becomes arrested by the methylene chloride the animals are much more readily and rapidly resuscitated through artificial respiration. In comparing the narcosis produced by pure methylene chloride and mixtures of

alcohol and chloroform, it was found that the addition of methyl alcohol to chloroform somewhat reduced the poisonousness of the latter without reducing its narcotic action, and therefore is to be preferred to pure chloroform as an anæsthetic. The mixture which they recommend consists of forty-five parts of chloroform to thirteen of methyl alcohol. They conclude their paper with the following sentences: First, that the substance heretofore employed as methylene chloride is a mixture of chloroform and methyl alcohol; second, this mixture is to be preferred to chloroform for the production of narcosis; third, that pure methylene chloride produces narcosis quite as rapidly and as profound as either of the above preparations; fourth, that the action of pure methylene chloride on the circulation and respiration is, by far, less dangerous than that of either of the other preparations.

GLEDITSCHINE.

IN a letter to the *Medical Record* of November 5 the genuineness of gleditschine is reasserted, and a proposition is made by Mr. Goodman, through Dr. Claiborne, to submit the leaves supposed to come from the *Gleditschia triacanthia* to a committee composed of medical men, a chemist, and a botanist, who are to determine, first, whether the leaves are really those of the tree which they have been supposed to represent; second, whether they contain any alkaloid; and third, if an alkaloid be found, whether it is an anæsthetic. We understand that Drs. George F. Shrady and F. P. Foster have agreed to serve upon the committee. Is it possible that there is an alkaloid gleditschine, which has really been obtained by Goodman, and that the intermediate druggists have, finding the demand greater than the supply, put upon the market a solution of cocaine under the name of gleditschine?

THE TREATMENT OF GOITRE BY SUBCUTANEOUS INJECTIONS OF ERGOTIN.

A CORRESPONDENT writes us inquiring the exact technique in the treatment of goitre by hypodermic injections of ergotin. In this he gives us an almost impossible task. It is but a short time since this method of treatment was introduced by Coghill, and the discrepancy between the few writers who have published communications on this sub-

ject is so great as to render it impossible to fix the exact status of this mode of treatment. Bauvens, writing in the *Journal de Médecine* for September, 1887, seems to have had remarkable success. His first procedure was to inject 16 minims of a solution containing one part of ergotin to seven of glycerin and seven of water. This proving unsuccessful, he then injected the same quantity of the solution of three parts of ergotin to seven of glycerin and water, and this proving somewhat efficacious, the strength of the solution was then increased to five parts of ergotin to seven of glycerin and seven of water, and in a period of two weeks four injections of 16 minims, which were administered. These injections were somewhat painful, and caused slight inflammation and swelling, but after three weeks both inflammation and goitre were claimed by Bauvens to have completely disappeared. He claims that the injection should not only be subcutaneous, but should be carried into the parenchyma of the gland.

Our own opinion is that the irritation produced by ergotin injections is so excessive as to render it almost unfit for hypodermic use. It is nearly generally acknowledged from experience in gynecological practice that the injections into the skin of the abdomen must be given up, and that the nates alone are fitted for such irritating injections, a fact already proved by the syphilologists for corrosive sublimate and calomel. On the other hand, great difficulty attends the selection of the most suitable solution, for as long as we are ignorant of the active principle of ergot, we can naturally not expect to get a constant preparation of its active principles. As a rule, the greatest reliance may be placed upon the watery extract of ergot. But this also causes troublesome local symptoms even when injected into the nates. A considerable part of the burning pain which follows the use of preparations of ergot is dependent upon their acid reaction. It has been found by Bumm (*Centralblatt für Gynäkologie*, August 28, 1887) that the ergot preparation might be neutralized by a slight addition of soda without interfering with its efficiency, but that the preparation cannot be kept in an alkaline condition on account of its tendency to undergo rapid decomposition. Another source of irritation lies in the concentration of the solution, since the objection to the larger quantity of fluid is not as serious as the local pain and inflammation caused by more concentrated preparations. Weak solutions are, besides, more rapidly absorbed than stronger

solutions, and it may be said that if five, or at most ten, per cent. of the watery extract twice purified, neutralized with soda and filtered, is injected into the muscles of the nates, the local irritation produced is not worth mentioning. As to whether a similar state of affairs holds for injections into the thyroid, or as to whether injections of ergotin offer better hopes of cure than enucleation, must as yet remain undecided.

Reports on Therapeutic Progress.

THE USES OF SACCHARIN.

Saccharin must be regarded from a two-fold aspect in its therapeutical effects and uses: first, antiseptic; and, second, sweetening. It is asserted by competent authorities—Aducco, Mosso, Stutzer, and Stadelman—that it approaches in energy such antiseptics as salicylic acid and thymol. On the other hand, it does not arrest or interfere with the normal fermentative action of the animal secretions in the stomach or intestine. It is without any action on ptyalin or pepsin. Nor does it appear to have any secondary action on the digestive secretions, passing quite unchanged out of the system through the kidney in the urine, in which latter it may be found within half an hour from its ingestion. The result is no different if it be injected subcutaneously or into the intestinal tract. It is not even found in the mammary secretions in either case. Yet so readily is it absorbed and eliminated that even when as much as seventy-five grains were taken daily no trace could be found in the system in twenty-four hours. Professor Leyden and other physicians—notably Drs. Salkowsky and Stadelman, who have used saccharin continuously in hospital practice both as a medicine and for dietetic purposes—state that even when taken in quantities far larger than are required for ordinary sweetening purposes with food, and over a long period of time, there were not the least injurious effects. So reliable are the reports on the use of saccharin in Germany that the authorities have authorized the completion of large contracts for the supply of tablets to the army. Thus it would appear that in saccharin we have an agent which is absolutely harmless in its passage through the system, eliminated from it unchanged without any deleterious effects, transitory or other, on the genito-urinary system, with sweetening properties three hundred times as strong as cane-

sugar, and free from the injurious results which, under certain conditions, follow from the decomposition of a carbo-hydrate in the system. How far, under what conditions, and in what secretions its special antiseptic properties may be utilized experience may determine, but even the simple fact that a pleasant antiseptic, harmless in operation on the tissues, can be passed through the body in a short time is one of both considerable moment and interest. That its antiseptic properties are manifested as an antifermentative agent in the urine has been proved by the researches of Mosso and Stadelman. It does not appear that this fermentative retarding influence of saccharin, from which we might have expected so much in cases of chronic cystitis, has as yet been shown to act curatively in this affection. But there are numbers of cases of rapidly-decomposing alkaline urine in which early fermentative changes promote the decomposition, when, it is only reasonable to argue, it would have a retarding and therefore beneficial action.

It is as yet rather a matter of surmise how we may apply the properties of saccharin in the treatment of various affections. In the *Medical Press* for October 12, 1887, DR. H. MACNAUGHTON JONES gives a number of indications for the therapeutic employment of this drug which are worthy of attention. So far, we naturally recur at once to true diabetes and those transient glycosuric states in which there are distinctly fermentative tendencies in the blood, as, for example, in epidemic furunculus and anthrax, and as we find frequently proved by the boils or carbuncles of diabetes mellitus. Careful experiments have shown that saccharin in solution greatly retards the fermentative progress of torulæ, and it would also be interesting to know what special influences on schzo-phytes or micro-bacteria solutions of saccharin possess. It has long been the desire of the physician to be able to administer in such acute infective diseases as smallpox and typhus fever antiseptic and antifermentative remedies which would not nauseate and might be palatable or capable of being disguised, and which in combination with antipyretic medicines would not interfere with the action or administration of these latter. It seems that, if we cannot yet assert that we have arrived at this much-desired object in this instance of saccharin, at least its discovery has shown that the acquisition of such an antiseptic as that referred to is possible. In the diluents, mannite, sugar of milk, and gluten, we have three most use-

ful means of administering saccharin therapeutically or dietetically in solid form. The tablets before alluded to are composed of saccharin, carbonate of sodium, with or without some other medium, as mannite. Powders ready prepared with the same diluents of various strengths may be had. Half of one of these pellets will be quite sufficient for the small cup of tea or coffee.

In gout, the necessary dietary may be made more bearable by the employment of saccharin; so, also, in the bladder-affections of old age and in biliousness it may be employed with advantage. In many cases of gastric catarrh, skin-affections, eczematic skin-affections in children, where saccharin food is counter-indicated, saccharin may be availed of for sweetening food and disguising the taste of medicines. In addition to these uses of saccharin, its value in pharmaceutical practice promises to be very marked. The mixture of six drachms of tincture of chloride of iron, two drachms of four per cent. solution of spirit of saccharin, renders this valuable preparation quite agreeable to the taste; so, also, equal parts of saccharin and fluid extract of cascara sagrada disguises the taste of this valuable aperient. Thirty grains of salicylate of sodium, with thirty drops of spirits of saccharin, in seven drachms of water, becomes quite palatable; so, also, the unpleasant but useful chloride of ammonium lozenges may through its use be rendered more agreeable. Saccharin might likewise be substituted for the sugar in a compound powder of liquorice, where the large amount of the sugar now present is against its frequent use as an aperient. The iodide of iron is, like the muriate, well disguised, and is a more permanent preparation when made up with saccharin than the present syrup.

In this connection the following notes as to the chemical properties of saccharin, published by MR. A. D. GRAVILL in the *Pharmaceutical Journal and Transactions*, are of interest. Saccharin now occurs as a very pale yellow, nearly white, amorphous powder, free from grittiness, but giving a distinct sensation of roughness when rubbed between the fingers. It is not entirely free from odor, but this is very slight and not at all objectionable, reminding one of a very slight flavor of essential oil of almonds. Its taste is intensely sweet and persistent, which in the raw state is followed by a slight harshness upon the tongue and palate. The sweetness is very distinct when diluted to 1 in 10,000. Under the microscope it presents no definite form of crys-

tallization. A temperature of 100°C ., even if continued for some time, has no perceptible effect upon saccharin; it loses no weight, and undergoes no physical change. It fuses at a temperature of from 118° to 120°C ., and at 150°C . forms a clear light yellow liquid, which boils a few degrees higher. At the latter temperature dense white fumes appear, and a condensation of tufts of acicular crystals (some well defined) is found upon the cool surface of the apparatus. These crystals, except for a slight sweetness of taste, correspond in characters and tests to benzoic acid. The sweet flavor may be due to the presence of a very small quantity of undecomposed saccharin, carried mechanically with the fumes. The escaping vapors, which are very irritable, and give a more decided odor of hydride of benzole than the powder itself, also communicate a very distinct sensation of sweetness to the back part of the palate. Heated over a flame, with free access of air, saccharin carbonizes and burns with a dull, yellow, smoky flame, leaving a residue amounting to 0.65 per cent. of sodium salts. It does not reduce an alkaline copper solution, but, like glycerin, liberates boracic acid from borax, the latter salt dissolving saccharin readily in aqueous solutions, due, no doubt, to a displacement of the boracic acid.

The strong acids, either hot or cold, show no characteristic color reaction; the compound enters solution at the boiling-point of the acid, and, in the case of hydrochloric, shows a white granular separation on cooling. Sulphuric acid develops an uncharacteristic light brown color.

The compound, like most of the organic acids, shows a characteristic reaction with ferro- and ferricyanide of potassium. In the former case no change is perceptible until boiled, when a greenish-white turbidity appears with the liberation of small quantities of hydrocyanic acid. In the latter case a trace also of this acid is set free, with the formation of a very distinct green solution, the latter reaction being very perceptible with a few drops of a 1 in 1000 solution of saccharin in water. Heated with lime, very distinct colors of benzoic aldehyde are developed.

Saccharin possesses very decided acid properties, and combines readily with alkalies or alkaline carbonates, forming andro-orthosulphamine-benzoates of the same, in the latter case at the expense of the carbonic anhydride, causing strong effervescence. These

combinations are very soluble in water, the alkaline carbonate thus forming a ready medium for the solution of this acid, which alone is so sparingly soluble. Another advantage of some importance is, that, while the harshness of flavor perceptible in a simple solution of the acid is destroyed, the great sweetness appears to be distinctly intensified and refined.

The following shows the solubility of the saccharin in the various liquids quoted, all, with the exception of the boiling water, being taken at 60°F . :

Boiling water.....	0.60	parts per 100 by volume.
Cold "	0.20	" " "
Alcohol, .800.....	4.25	" " "
Rectified spirit, .838.....	3.20	" " "
Ether, .717.....	1.00	" " "
Chloroform, 1 49.....	0.20	" " "
Benzene.....	0.40	" " "
Petroleum ether.....	Insoluble.	

It is also sparingly soluble in glycerin and fixed oils, and, to a greater or less extent, in volatile oils. Benzoic aldehyde dissolves saccharin in large quantities.

Mr. Gravill states that he was somewhat disappointed at the slight solubility of saccharin in ether, as it has been repeatedly stated to be very soluble in that liquid.

The quantity of saccharin required to communicate an agreeable degree of sweetness, like sugar, differs with the material to be sweetened, but from one-half to one and one-half grains, according to taste, will be found sufficient for an ordinary breakfastcupful of tea or coffee infusion.

EFFECTS OF HOT WATER UPON THE UTERUS.

As a result of his experiments upon rabbits, M. MILNE MURRAY, in the *Revue Médicale*, reports that,—

1. The non-gravid uterus of the rabbit is subject to rhythmical contractions, one every two minutes.

2. The introduction of water at 105° to 110°F . produces an immediate state of tetany of the uterus, lasting from five to thirty minutes.

3. The muscular contraction is accompanied by simultaneous contractions of the smaller vessels, and the organ becomes exsanguine. The contraction of the vessels disappears gradually before the muscular spasm, and is not followed by dilatation.

4. Water, at 32° to 42°F ., produces, after

thirty to fifty seconds, a less energetic spasm than water at 105° to 110° F.

5. The spasm is easily reproduced at short intervals by stimulating the uterus with hot water. It is not reproduced at a long interval by hot water.

6. A faradic current of short interruptions acts in the same way as hot water, and produces tetany.

These results serve to explain the employment of irrigation in the treatment of uterine affections.—*Medical Press*, October 19, 1887.

THE ANTAGONISM OF DRUGS.

Recent investigations render it probable that alkaloids or extractives formed from food in the gastro-intestinal canal, or from the tissues of the body, cause many of the diseases we are called upon to treat. These alkaloids or extractives arise from physiological or morbid changes, and if in undue quantity, or if not quickly eliminated, they may act like poisons introduced into the system from without. Some of these ptomaines and leucomaines produce effects similar to vegetable alkaloids, as, for instance, atropine, muscarine, or curare. Indeed, muscarine can be obtained not only from the fungus *agaricus*, but also from animal tissues.

In the *British Medical Journal* for November 12, 1887, DR. SIDNEY RINGER shows that some inorganic and organic poisons may be completely antagonized, the normal function being restored, and this being so, warrants the hope that with more accurate information we may be able to obviate the effects not only of inorganic and organic alkaloids introduced into the system, but the effects of ptomaines or leucomaines engendered in the animal body. Probably some of our success in treatment is due to our drugs antagonizing these products.

A short time ago an interesting controversy arose regarding the reciprocal (mutual) antagonism of drugs. On one side it was maintained that drugs might be mutually antagonistic, while other observers denied this statement. The former maintained that the effect of a drug might be antagonized by a second drug, which, if increased in quantity, would manifest its own individual effects, but these effects could be removed by increasing the quantity of the first drug. To take an example, atropine will antagonize the action of muscarine, and muscarine the action of atropine on the heart. To take another in-

stance, atropine will antagonize the action of jaborandi on the submaxillary gland, and *vice versa*; if, after atropine has antagonized the action of jaborandi, a further quantity of jaborandi is administered, it will overcome the action of atropine and salivary secretion will return.

Rossbach disputed this, and maintained that while one drug increases another depresses or suspends function, and the drug which increases function can never overcome the effect of a drug that has abolished function. He admitted that when atropine arrests the secretion of the sweat-glands pilocarpine may produce perspiration, but he asserts that this occurs only with a small dose of atropine just sufficient to paralyze the secretory nerves, but not the secretory cells of the gland, and that pilocarpine stimulating the cells may produce perspiration. But he maintains that a larger dose of atropine paralyzes both the secretory nerves and the secretory cells, and after this stage no amount of pilocarpine will excite perspiration.

Dr. Ringer demonstrates that the effect of a toxic dose of calcium chloride on the detached ventricle of the frog's heart can be quite antagonized by a toxic dose of potassium chloride, and, *vice versa*, that a toxic dose of potassium chloride, sufficient not only to arrest spontaneous beats, but sufficient to prevent a strong induction shock exciting any contraction, can be antagonized entirely by a toxic dose of calcium chloride, and by the careful apportionment of the two salts their antagonism can be so nicely balanced, that the ventricle will beat spontaneously and quite naturally. Moreover, a toxic dose of potassium chloride will antagonize a toxic dose of veratrine, and, *vice versa*, a toxic dose of veratrine will antagonize a toxic dose of potassium chloride, and these two substances may be given with such equipoise as completely to antagonize each other, so that the ventricle will beat quite naturally and spontaneously. So that in the case of calcium chloride and potassium chloride, and again in the case of veratrine and potassium chloride, we may have in the circulating fluid two of each series present in toxic doses without either poison exerting any apparent influence on the ventricle, which goes on beating spontaneously and normally; but, if one salt were administered singly, it would powerfully affect the functions of the ventricle to an extent incompatible with life.

Referring first to physiological antagonism, Dr. Ringer shows that if the ventricle of the

frog, or of the eel, or of the tortoise, is fed with saline solution (.66 per cent.), contractility soon ceases, and cannot be induced by a strong electric shock. On the addition of a lime-salt, even in very minute proportions, as 1 part of lime-salt to 10,000 parts of saline solution, contractility immediately returns, but the contraction is abnormal, for the dilatation of the ventricle is greatly prolonged, so that the whole contraction lasts much longer than natural. The addition of a small quantity of a potassium-salt, as, for instance, potassium chloride, 1 part in 15,000 of circulating fluid, obviates this effect of the calcium-salt, accelerates dilatation, and induces a perfectly normal beat, and with such a solution good contractions are sustained for several hours. Here, then, we have an antagonism between lime- and potassium-salts, affecting, however, only one part of a contraction,—namely, the relaxation of the contracted muscle.

Not only are the salts of these two substances—potassium and calcium—antagonistic in physiological doses, but they are likewise antagonistic in toxic quantities.

If to a solution capable of sustaining the ventricular contractions we add a toxic dose of potassium chloride, the contractions speedily cease, even when the ventricle is strongly stimulated. Now, on adding a toxic dose of calcium-salt, the potassium chloride is antagonized, and, if the calcium-salt is added in suitable quantity, complete contractility is restored, and the ventricle beats spontaneously and normally; and, *vice versa*, if we add to the circulating fluid a toxic dose of calcium chloride, we greatly prolong the duration of the contraction, and especially retard relaxation; but, on the addition of a toxic dose of a potassium-salt, these lime effects are obviated, and normal spontaneous contractions ensue.

Here, then, we have instances where two substances in toxic doses so antagonize each other that natural beats occur; while either substance, added alone to the circulating fluid, powerfully affects the functions of the ventricle to an extent incompatible with life.

We are able, however, to analyze the antagonism between these salts more minutely still. During a contraction, four distinct sets of changes occur in the muscular tissue of the ventricle,—namely, changes occurring during the latent period, during the period of contraction, during the period of relaxation, and reparative changes, independent of those permitting relaxation. Now, potassium-salts, like

veratrine-salts, greatly retard these reparative changes, so that in a ventricle poisoned by potassium chloride, these reparative changes are very slowly performed, and hence, after the completion of contraction and relaxation, if a subsequent contraction is soon induced it is a very weak one; or, if the stimulus is too soon applied to the ventricle, no contraction may occur, and cannot be induced till a short time has elapsed, and then the amount of contraction depends on the length of the diastolic pause. This effect of potassium chloride on the reparative changes a calcium-salt completely obviates.

We see, then, that a potassium-salt accelerates relaxation but retards reparation, in both these respects being antagonized by a calcium-salt, and *vice versa*. Another antagonism between potassium- and calcium-salts still remains to be noticed. If a ventricle be allowed to remain without contracting from a few seconds to a minute, then, on exciting it, the first contraction is weak, and the subsequent contractions grow gradually stronger till normal contractions occur. This staircase character of beats depends on the action of the potassium-salt in the circulating fluid, and the degree in which it occurs is in proportion to the relative amount of potassium chloride in the circulating fluid. A calcium-salt, as calcium chloride, quite obviates this effect. If sufficient calcium chloride be added, no matter how long the ventricle remains without contracting, the staircase character of the beats is prevented, or is very slight indeed.

Strange as it may appear, veratrine affects the ventricle much after the manner of lime-salts. Thus, added to simple saline solution, it will restore contractility; and further, like lime, it greatly prolongs the duration of the contraction, and especially delays relaxation of the contracted ventricle, and, like lime- and potassium-salts, we find veratrine- and potassium-salts are mutually, or reciprocally, antagonistic.

For instance, the addition of veratrine to the circulating fluid produces either great irregularity in the contractions, or very great delay in dilatation, according to the temperature of the room. This irregularity a toxic dose of potassium quite removes, and good spontaneous contractions return. Further, if the ventricle is greatly weakened or arrested by adding a toxic dose of potassium chloride, veratria quite antagonizes the potassium chloride effects, and restores spontaneous and normal contractions.

Barium- and calcium-salts, as might be expected from their chemical relationship, have many actions in common. It is interesting, too, that, although lime-salts and barium-salts both broaden the beat, causing fusion and contracture, barium-salts effect this more powerfully than calcium-salts, yet after barium has produced its effects, on the addition of a calcium-salt, instead of obtaining the sum of their united action the effects common to both salts become less. In other words, lime takes possession of the muscular tissue, excluding the action of the barium-salts. It would appear, then, that two substances affecting the same tissue in the same way, when administered therapeutically, one will not necessarily intensify the action of the other, but may replace the other, and we get the action of only one substance, and this, while having a greater affinity for the tissue, may induce a less physiological effect.

These results are very interesting, and have considerable importance, both physiologically and therapeutically. Thus, we have seen that barium and calcium both exert an influence in the same direction, but the barium molecule is the more active in respect of its influence of the ventricular contraction. If, however, we bring both molecules into action simultaneously, we see that the resultant effect, instead of being greater than with either component, is less, the lime displacing the barium and inducing its less physiological disturbance. The relation of this subject to practical medicine is very clear and important, for on the question of the combination of two drugs we must remember that the joint action of two drugs functionally similar is not necessarily greater than that of either separately, and may be even weaker than one of them given separately; for in some instances two substances having the same action do increase the action of either separately, so that we get the sum of their joint action. This is the case with lime and veratrine.

So far we have seen that substances may be antagonistic in two ways. The first we may term physiological, for instance, where two substances inducing an opposite physiological effect on a tissue may be so adjusted that the poisonous action of both is prevented. In the other case the antagonism is probably chemical, and one substance may by a stronger chemical affinity displace another poison, and this may occur, and, indeed, is most likely to occur, when both substances are chemically related and have a similar physiological effect.

But there are other ways in which a substance may act as an antidote.

A lime salt in the circulating fluid, we have seen, is necessary for the contraction of cardiac muscle. Now, a soluble oxalate destroys function, in part by combining with the lime in the circulation, and rendering it insoluble and so inoperative. Here, then, we obviate the poisonous effects of an oxalate by adding lime to the circulation. There are still, however, other ways in which we can antidote a poison. A soluble oxalate not only withdraws function by withdrawing lime, but is directly to some extent poisonous to the cardiac muscular tissue; and this poisonous action we obviate by the administration of a lime-salt, which combines with the oxalic acid, forming an insoluble, and therefore inoperative, compound. To take another instance, soluble barium-salts are poisonous to the cardiac muscle, and arrest the ventricle in systole. Now, the addition to the circulating fluid of a solution of sulphate of sodium will precipitate the whole of the barium, and the ventricle will speedily resume its normal contractility, even though the contractions had been suspended for an hour. The effect of the sodium sulphate is very rapid. Barium-salts, one would think, can prove poisonous only to the tissues after more than enough has been absorbed to combine with the whole of the sulphuric acid in the blood and tissues, and it is possible that part of the action of a barium-salt may be due to the withdrawal of sulphuric acid from the tissues.

Finally, there is another way by which the poisonous action of some substances can be greatly lessened. Some poisons prevent the changes which take place in the exercise of a function, as, for instance, the contraction of the muscle. They do not destroy the structure, they only suspend function, and this power they possess only when the poison reaches a certain percentage of the circulating fluid. If the fluid is diluted, then the percentage amount becoming less, the poisonous action is greatly reduced. This is the case with potassium and most other salts. This fact probably explains the effect of bleeding, which has been successfully employed in some cases of poisoning, and is highly successful in uræmia. The loss of blood induces a rapid absorption of the intercellular fluid and water from the gastro-intestinal canal, and so diluting the poison, lessens or removes the symptoms. If bleeding proves unsuccessful the influence of dilution suggests transfusion of a saline solution, also the free ad-

ministration of liquids by the stomach, methods Dr. Ringer long ago suggested.—*Brit. Med. Jour.*, November 12, 1887.

CREOLINE: A NEW DISINFECTANT.

DR. F. VON ESMARCH, assistant at the Royal Institute for Hygiene in Berlin, publishes an important and interesting article in vol. ii., Nos. 10 and 11, *Centralblatt für Bacteriologie*, etc., upon a new disinfectant—*creoline*—which will at once arrest the attention of students, the more especially so since Prof. Dr. Eugene Fröhner, of the Royal Veterinary High School, has confirmed, by the most careful experiments, the views expressed by Dr. von Esmarch. Dr. Fröhner describes the results as "astonishing," both in regard to internal administration and external application, and believes that its use in mange and itch will be of value in political economic studies. Experiments were made with creoline and carbolic acid with decomposed material, Asiatic cholera, typhoid, and anthrax; the minutest tables of analysis are given in seconds, minutes, hours, and days, all the changes being noted, and, with the sole exception of the bacilli and spores of anthrax, creoline proved itself to be the most powerful germicide. As yet, Dr. von Esmarch is unable to say why it fell behind carbolic acid in anthrax. In the first trial the results were equal, but in the second experiment creoline did not manifest such germicidal power as the carbolic acid. Dr. von Esmarch says, "All of my liquids were thoroughly decomposed, and emitted a most offensive odor. This disappeared almost entirely when a small quantity of creoline was added, and the mixture agitated every few seconds. The same addition of carbolic acid produced no effect, even when a much larger percentage was used." He also adds, "The action of *creoline* preparations surpasses by far those of carbolic make."—*Boston Medical and Surgical Journal*, November 10, 1887.

THE ANTISEPTIC TREATMENT OF WOUNDS.

MR. W. J. PENNY summarizes the important points in the antiseptic treatment of wounds as follows:

"To recapitulate the antiseptic or aseptic treatment of wounds: 1. Arrest all hemorrhage, thus preventing the accumulation of blood-clot, the nidus for development of

micro-organisms. 2. Remove all foreign bodies, such as dirt, detached pieces of bone or tissue. 3. If foreign bodies or micro-organisms have gained an entrance, purify thoroughly with an efficient antiseptic. 4. Provide very free drainage, in the most dependent part if possible. 5. Bring the parts into accurate apposition, like to like; but carefully avoid tension, especially of the edges of the wound or in damaged or unhealthy tissues. 6. Apply a large dressing sufficiently impregnated with a reliable antiseptic, and very absorbent and elastic. 7. Bandage firmly and evenly to get elastic compression. 8. Elevate the part to lessen the blood-pressure and effusion while the vessels are weak from the injury. 9. Give absolute rest; change the dressing as little as possible. Visible discharge is the indication if the dressing is reliable. 10. Attend to the general health and give a free supply of good food and fresh air, in this way promoting the resisting and healing power of the tissues. Recognition of these principles, their study and adoption, are of as much or more importance to a surgeon than a knowledge of anatomy or manual dexterity. By them you take surgery out of the region of chance and make it much more an exact science. If you happen to have an infectious case, let me impress upon you, gentlemen, not to look on it as an unavoidable accident, but recognize it as being due to some mistake in your chain of treatment, to be found out and in the future guarded against. None of us are free from mistakes or accidents; the best surgeon is he who has the least number, who recognizes that he is not infallible, but strives to discover his mistakes, and from them learns lessons for his future guidance."—*Lancet*, October 29, 1887.

ACETANILIDE AND ANTIPYRIN IN THE TREATMENT OF EPILEPSY AND CERTAIN ALLIED DISORDERS.

The control of antipyrin and acetanilide manifest over the nervous system has led many observers to use them in the treatment of a variety of nervous affections. Medical journals at home and abroad have devoted considerable space to the reports of cases so treated, which, as yet, are, however, so few in number as to scarcely warrant the deduction of any positive conclusions. DR. JOSEPH LEIDY, JR., in the *New York Medical Journal* for October 29, 1887, reports a number of cases of epilepsy, hystero-epilepsy, hysteria, insomnia, neuralgia, and lumbago in which

these drugs were used, with results which, though encouraging, are hardly sufficient to warrant their maintaining the position which many have alleged for them. The cases of epilepsy were selected irrespective of their causation or variety. Those of *tabes dorsalis* were all of syphilitic origin. Headaches were mostly of the congestive type. Neuralgias consisted of the trigeminal, intercostal, visceral, and suboccipital varieties. Notes of thirteen cases are published, which were evidently those in which the results of these drugs were most favorable. Dr. Leidy summarizes his results as follows :

Of thirty-six patients with epilepsy, fourteen were greatly benefited by acetanilide and three by antipyrin. Acetanilide aggravated the attacks in four cases.

In five cases of hysteria antipyrin proved itself a useful remedy, and worthy of further trial ; the results from acetanilide were negative.

In three cases of hystero-epilepsy the results from both drugs were negative.

In four cases of insomnia the use of acetanilide was attended with some benefit. Antipyrin failed signally, although in one case, due to nervous exhaustion attendant upon sexual excesses, it proved effectual in relieving the headache and producing a refreshing sleep.

In fifteen cases of supraorbital and suboccipital neuralgia, nine were greatly relieved by acetanilide and four by antipyrin.

In two cases of intercostal neuralgia acetanilide gave immediate relief.

In five cases of nervous headache great benefit was obtained from acetanilide. Antipyrin proved of doubtful utility.

Of seventeen patients with sciatica acetanilide benefited eight ; negative results with the remainder.

Of ten cases of lumbago, seven were relieved temporarily and two permanently by acetanilide.

In six cases of rheumatism pain was greatly relieved by acetanilide, and in one case by antipyrin.

In five cases of *tabes dorsalis* the gastric crises and headache were relieved by acetanilide, formication disappeared in four cases under observation ; in one case no benefit was derived.

In conclusion, it may be said,—

1. *In epilepsy*, when acetanilide does good, its action is rapid ; it does so by diminishing the violence and number of the attacks, and, as it has a tendency to aggravate the disease

in some cases, the nature of which could not be determined, although it occurred only in those cases with a marked hereditary predisposition, its use should not be continued over two weeks unless some benefit has been obtained.

Cases of *petit mal* prove the more amenable to treatment, though in two cases of *haut mal* the drug was of great service. Antipyrin has proved itself inferior in every respect to acetanilide. Neither remedy is to be used as a substitute for the bromides, but simply as an addition to the limited number of drugs now at our command.

2. *As an analgesic* acetanilide has proved itself a valuable remedy ; the majority of the cases treated have been benefited. Antipyrin appeared beneficial in several cases, though it is not to be ranked with acetanilide.

3. *As a hypnotic* further experimentation is needed, but from the cases under observation both drugs are of doubtful efficacy.

In the administration acetanilide was used first and considered the safer drug. From acetanilide there are no objectionable after-effects, except it be cyanosis, which only occurs after the ingestion of large doses, and usually in cases attended with marked elevation of temperature ; on the other hand, collapse, disturbances of the gastro-intestinal tract, respiration, and circulatory apparatus, with fatty metamorphosis of the liver and kidneys (Dr. Porter, in *New York Medical Journal*), prove sufficient objections to the use of antipyrin.

The dose of acetanilide varied from gr. iii to x ; that of antipyrin from gr. x to xv.

TERPINHYDRATE.

DR. S. RABOW says in the *Therap. Monatshefte* for August, 1887, that among the many new remedies which have found their way into therapeutics, terpinhydrate and terpinol have chiefly come into use. If oil of turpentine and water be allowed to stand for a time, upon the walls of the vessel will be found small needle-like crystals. These are nothing else than terpinhydrate, or more correctly, terpin-dehydrate ($C_{10}H_{14} \cdot 2H_2O + H_2O$).

The production of this interesting body is as follows : A mixture of four parts of rectified oil of turpentine, three parts of alcohol ($80^{\circ} C.$), and one part of nitric acid is put in large, shallow porcelain dishes and allowed to stand for three or four days. The crystals which have formed are then collected and allowed to drain thoroughly ; they are then pressed between absorbent paper, and are re-

crystallized in a cold solution of ninety-five per cent. of alcohol. The product is about twelve per cent. of the original turpentine oil.

Terpinhydrate is a large, colorless, odorless, rhombic crystal, having a faint aromatic taste. It is with difficulty dissolved in cold water and turpentine oil, more readily in hot water, alcohol, ether, or carbohydrates.

The first careful examination of its physiological actions was conducted by Lépine, of Lyons, in the year 1885. He found that the drug had a similar action upon the respiratory organs as the oil of turpentine, and also acted similarly both upon the kidneys and nervous system. Lépine states that small doses (.2 to .6 grm. = 3 to 9 grs.) increase the bronchial secretions and facilitate expectoration. Large doses diminish the secretions and lessen the respirations to a marked degree, and produce a cessation of expectoration. The author has used the drug in over two hundred cases of bronchitis, using the above-named small dose, almost invariably obtaining the desired results.

Germain Sée found that large doses were useful in different states of phthisis pulmonalis in the checking of the copious secretions.

In cases of bronchitis where the bronchial tubes were surcharged with secretions and when dyspnoea existed, the remedy always acted with certainty. Also in fresh hæmoptæ it proved to be an invaluable hæmostatic, as it produced its results more rapidly than ergotin.

Kien, Clermont, Ferreira, Morra, Chéron, and others have recently referred to its value in diminishing the secretions in bronchitis and bronchocele. The usual dose advised being from .75 to 1 grm. (12 to 15 grs.) daily.

Guelpa alone reaches different conclusions. He gives but little weight to the effect of terpin upon the mucous membrane of the bronchia or its effect on the kidneys, and hence throws it aside, substituting for it terpinol.

Lépine also found that terpin acted upon the kidneys, and thus could be regarded as a direct diuretic.

Small doses are sufficient to cause a marked increase of urine. Its value for affections of the kidneys is judged to be highly probable, as large doses given to dogs have resulted in hæmaturia and albuminuria. Its asserted value in cystitis and chronic gonorrhœa requires additional evidence.

The well-known property of turpentine oil of relieving certain neuralgias, especially of the ischias, etc., is observed by Lépine to be

also a property of the terpinhydrate. He found in many such cases that doses of 1 grm. (15 grs.) of terpin afforded as much relief as would be given by several grammes of the oil of turpentine. According to our present knowledge, the use of the drug may be continued for a long time without producing injurious effects.

The only disagreeable accompanying symptoms which have been observed (and these rarely) are purging, pain in the epigastric region, and meteorismus.

In order to avoid these symptoms it is advisable to take the remedy during meals.

The size of the dose depends very naturally upon the nature of the result desired. Daily doses of .2 to .5 grm. act as an expectorant, whilst doses of 1 grm. *pro die* check the secretions, and may be also used to alleviate pain. It may be given in the form of pills or in wafers, or in a dilute alcoholic solution.

R Terpini hydrat., 3 grm.;
Sacch. alb.,
Mucil. gum arab., q. s.
Ut f. pilul. No. xxx.
S.—One pill three times a day.

R Terpin. hydrat., 10 grm.;
Spirit., 150 grm.;
Aq. dest., 100 grm. M.
S.—One tablespoonful three times a day.

R Terpin. hydrat., 5 grm.;
Glycerin, 30° C.,
Spirit., 95° C.,
Syrup simpl., aa 70 grm.

(The terpin should be dissolved in the warm glycerin, and the mixture of alcohol and syrup. simpl. should be added, and the whole well shaken. Each tablespoonful contains about .5 grm. of terpin. *Vigier and Chéron.*)

The author's experiences with terpin hydrate are very favorable, and sufficient, he says, to warrant his giving conclusive testimony as to its value. As, however, many questions upon the subject have been directed to him, he went still further and instituted inquiries among several practitioners who had large and valuable opportunities of observing its effects. He speaks of being especially indebted to Dr. Lazarus, of Berlin, and to Dr. R. Hausmann, of Meran, for a full and interesting statement of their experiences. Dr. Lazarus writes as follows:

"I consider the pill form the most useful, as in the solution so large an amount of alcohol is necessary that the effects of the latter are considerable. I have also seen that even doses of 1.5 to 2 grm. daily, when taken in pill

form, and during meal-time, produce no unpleasant symptoms. Indeed, I believe that only large doses can be depended upon to give an assured result.

"When an intense irritation of the mucous membrane of the bronchi is observed, accompanied by a meagre secretion, the use of terpin is indicated. It always increases the secretion, making it more watery. It lessens the irritation and aids and facilitates expectoration. In eight to fourteen days the catarrhal symptoms gradually disappear. My observations, which have resulted from wide experience, will be endorsed by very many of my colleagues who have largely used this remedy."

Dr. Hausmann does not write quite so favorably. He says,—

"Sée says in the third part of his 'Medical Clinic,' page 225, 'Terpin is an energetic modifier of the respiratory mucous membrane and a strong antiseoretorium. It lessens the secretions in pulmonary catarrh and chronic bronchitis.' Although I have firmly adhered to the use of terpin in pulmonary and bronchial catarrh I have never yet observed a complete stoppage of the secretion, although I have given doses of .80 to 1 grm. daily. In nearly all the cases, although the secretion diminished with rapidity, I observed the effects to be but temporary. I have noticed, however, that patients have been able longer to endure the use of terpin than turpentine oil. Sée believes that after a continued use of the drug no gastro-intestinal troubles result; but my opinion is that this is questionable.

"I have found neither the pill form nor the alcoholic solution so valuable as the practice of giving it in wafers.

"As a deodorizer the oil of turpentine is decidedly better than terpin."

JHAMBUL—A NEW REMEDY FOR DIABETES.

The jhambul is a small evergreen tree, indigenous to the humid region of India, especially to the Malayan peninsula. Both the bark and the seeds in this plant would seem to possess medical properties, the seeds apparently being more active. Dr. W. H. MORSE, writing in the *Maryland Medical Journal* for October 29, 1887, states that he has employed the powder of the bark and seeds in doses of 5 grains three times a day. He claims that the effect of this drug is to increase the vaso-motor and reflex functions of

the spinal cord, producing a general rise in blood-pressure, especially in the renal arteries. Nausea is occasionally produced, and respiratory movements are increased in number and depth and intestinal peristalsis increased. In diabetes it is said to lessen the specific gravity and quantity of the urine and diminish the amount of sugar, while the abnormal thirst and other unpleasant symptoms of the disease are overcome. Before endorsing these statements, which we must admit are apparently confirmative of other papers on the same subject, we must wait for extended experience. To be sure, if the drug proves successful in arresting these diseases, we can afford to laugh at the explanation of its action, given as follows by Dr. Morse: "The formation of sugar in the urine is arrested by a prevention of the formation of starch."

ANTIPYRIN IN SEA-SICKNESS.

The Paris correspondent of the *Lancet*, November 12, 1887, writes: "The Société de Biologie has devoted part of its last two sittings to the discussion of the different means recommended for the relief of sea-sickness. A note was presented by M. Hentz on the best way of administering cocaine, and received without any expression of opinion. M. Dupuy said that sea-sickness was more severely experienced by dyspeptic subjects, and particularly those who had dilatation of the stomach. In eleven cases he had given antipyrin in doses of from 2 to 3 grammes for a few days before embarking, and the patients had all informed him that they had been free from sickness. M. Dastre said he had instituted a series of experiments upon animals, imitating as closely as possible the movements of 'pitching' and 'rolling.' He had found that there was an incredible displacement of the abdominal viscera, which strike against the diaphragm and cause the gastric uneasiness. The body struggles with these displacements by means of muscular contractions, and the respiratory rhythm accommodates itself to them. Professor Brown-Séquard remarked that this theory of visceral displacement was very old, and one which he had been able to verify in his frequent passages across the Atlantic. It was evidently the view entertained by Wollaston, who recommended Arago to place a pad over his stomach when he crossed the Channel. M. Maurel had no doubt as to the influence of the stomach, but thought the cerebral shock

also played a part in the determination of the symptoms, inasmuch as the sickness always occurs when the boat is going down, never when it is being lifted up. The best preventive was lying on the back. Beyond the statement that sea-sickness is associated with dilatation of the stomach, and the hope held out by M. Dupuy that in antipyrin we now possess a remedy for it, there was nothing new in the views expressed by the different speakers. I have referred, however, at some length to the subject, because, my own seafaring experience has been somewhat extensive, extending over intervals during the last fifteen years, and including some kind of trial of every new drug recommended. Until a month ago the plan I always recommended was to take bromide for some days before going on board, and, if discomfort was felt notwithstanding, the dorsal decubitus was to be adopted. This, together with champagne, is generally what the transatlantic captains advise. In a recent trip to New York I tried two other remedies. The surgeon of the ship recommended me tincture of capsicum, and I had also taken a supply of antipyrin. As far as one case goes the result of the antipyrin was most satisfactory, and I can to this extent endorse the experience of M. Dupuy. The capsicum was also serviceable as a palliative, for several persons who had taken it continued to ask for it, but it did not arrest the sickness like antipyrin. A fellow-passenger who suffered from dilatation of the stomach with *clapement* was not sick at all."

THE PHYSIOLOGICAL ACTION OF THE OIL OF TURPENTINE.

Notwithstanding the fact that the oil of turpentine has been used for many years with success in certain morbid conditions, but little effort has been made to study its relation with the animal organism other than by the bedside. DR. H. A. HARE, in the *Medical News* for November 19, 1887, relates a few experiments which he has made in this connection, of which the following is a summary:

1. The oil of turpentine in small doses, resembling those ordinarily given in practical medicine, produces an increase in the number of the cardiac beats due to a direct stimulant action on the heart.
2. In larger doses it produces distinct slowing of the pulse, due to a stimulation of the pneumogastric or inhibitory centre.
3. That its influence on the vaso-motor

system, if at all, is very slight, either with large or small doses.

4. That poisonous doses (5 c.c. to 10 c.c.) (≈ 80 to 160) produce death by cardiac failure when injected directly into the jugular vein.

5. That the drug in small doses increases reflex action somewhat, but in large doses decreases it, the increase being due to a stimulation of the spinal cord, and the decrease due to depression of the sensory side of the cord and afferent nerves.

CHLORIDE OF AMMONIUM IN THE TREATMENT OF HEPATIC DISEASE.

In his monograph on the treatment of hepatic disease, SURGEON-GENERAL W. STEWART showed that chloride of ammonium in hepatic congestion produces a local depletion from the portal capillaries with each succeeding dose of the drug, and at the same time, by a species of auto-transfusion from the portal into the general circulation, the entire portal system, from its origin in the venous radicals in the intestinal mucous membrane, is freed from engorgement, and thus the liver is not relieved from congestion and its functions restored, and the occurrence of dysentery, so apt to supervene in hepatic congestion, and particularly in tropical abscess, is prevented. The depletion of the congested abdominal viscera thus effected, unlike that by leeches or other local means, is not attended with depression or loss of vital fluid, a loss which, in such cases, is but ill borne. Since the publication of his first paper on this subject in 1870, Dr. Stewart states that his experience with this drug has been quite extensive, and he is able to confirm the testimony of Murchison, that in doses of 20 grains two or three times daily it induces free diaphoresis, increases the flow of urine, diminishes the portal congestion, and relieves hepatic pain. He also believes that it stimulates the absorbents, especially those of the liver, and would seem to affect absorption of hepatic abscesses.

The symptoms produced by this drug in hyperæmia of the liver are stated by Dr. Stewart to be characteristic, and are specially to be noted, since, so far from being evidences of the medicine disagreeing, they are signs of its successful action. They are only evident as long as the liver is congested, and Dr. Stewart even goes so far as to claim that their occurrence after the administration of the drug in any given obscure case may be considered

diagnostic of hepatic disease. The symptoms now to be described occur shortly after the medicine is taken, in from five minutes to half an hour. Sometimes a "shock" is felt, or as if "something gave way" in the side; at other times a succession of shocks is experienced in the hepatic region, accompanied or not by a pricking sensation ("pins-and-needles"), or as if cold water were trickling down the side; or the action is described as that of "a pulling" from one hypochondrium to the other, or from the margin of the right costal arch upwards and backwards, as if through the liver; or a "clawing," "working," or "gnawing sensation" is spoken of as felt by the patient. When a single sharp shock is experienced in a debilitated, nervous, and susceptible subject, it is often severe. Immediately afterwards, however, the severe hepatic pain vanishes, and never again returns with its original severity; and with each succeeding dose a sensation of "pulling" only is felt in the hepatic region, till at length all sensible action ceases with the removal of the hepatic congestion, the case being one of simple enlargement of the liver. With the local actions excited in the liver and related parts—through reflex nervous action—when a full dose of the drug has been taken, motor impulses are similarly communicated to the muscles of the intestinal canal, causing its peristalsis to become more rapid and energetic, as evidenced by the "twisting" and other movements experienced in the situation of the duodenum, or all over the abdomen, and which at times are more sensibly felt in particular parts, in the situation of the umbilicus, or in the inguinal region. Simultaneously with or closely following the above phenomena, the abdominal muscles may be thrown into tonic contractions, which are perceptible at times to both sight and touch; and pulsatile movements are felt, and are sometimes visible, along the margins of the right inferior ribs. All these phenomena are highly purposive, contributing, with other vital actions and processes brought about by the drug, to diminish portal congestion, restore the diseased liver to a healthy state, and afford relief to the entire system.

The following is a summary of the auxiliary treatment, diet, and management of congestion of the liver, and mode of administering the ammonium chloride:

Bearing in mind what has been said of the therapeutic effects of the drug in hyperæmia of the liver, and the indications to be drawn from the symptoms and pathology of the dis-

ease, the first thing to be done is to put the patient to bed, there to remain, in acute cases, during the whole course of the disease; in short, till the congestion, pain, and general and local distress and uneasiness shall have subsided, and that the patient may have no occasion to quit his bed, a bed-pan and urinal should always be at hand, as well as a trusty attendant to minister to his wants. By the recumbent position and the avoidance of all sudden and violent movements, mechanical rest and support are given to the enlarged, weighty, and oppressed or painful organ. The horizontal position, too, facilitates the auto-transfusion of the blood from the portal system, through the hepatic capillaries, into the general circulation, under the influence of our special remedy,—a process which will be better understood now that the reader is in possession of the details of the local signs expressive of the effects produced by it: the excitation of the muscles of the intestinal canal to increased peristalsis, and those of the abdomen and thorax surrounding the liver to tonic contractions, by which muscular pressure is brought to bear on the radicals of the portal vein, and on the liver and gall-bladder, which not only hastens forward the entire portal stream, but may squeeze out of the liver some of the superfluous blood, as well as free it and the gall-bladder from retained bile. By the increase of the functional activity of the liver, as well as the increased flow of blood to the skin, as a further result of its action, a *vis a fronte* is brought into play in aid of the *vis a tergo* above described, by which the equilibrium of the entire circulation is speedily restored. The free perspiration induced by the drug is also promoted and chills avoided by the rest and warmth of bed. It is to this latter stage of its operation that much of its value is due,—the free diaphoresis favors sleep, while the nervous system generally is exhilarated and soothed, and the patient almost entirely relieved from all his distressing symptoms.

It is equally important that the congested (or, it may be, inflamed) liver should enjoy, as far as possible, physiological rest. To this end, on no account must solid food be given to the patient, and wine, beer, or other alcoholic stimulants must be strictly prohibited. The diet must be of the least irritating character, and only small quantities of milk, beef-tea, or farinaceous articles should be taken at a time. Barley-water may be taken freely as a drink. If there be diarrhoea, the patient passing frequent loose bilious or dark-colored

motions, a pill composed of two grains of mercury and three grains of Dover's powder, repeated every two hours till four or five have been taken, will be found the most effectual means of checking it without the risk of setting up gastro-intestinal irritation. Looseness of the bowels, however, does not contraindicate the use of the chloride of ammonium,—indeed, it is in itself the best remedy in cases of diarrhoea associated with hepatic congestion. The only condition which contraindicates the immediate use of the drug in acute cases is the existence of a combined hot and dry state of the skin with pyrexia. Under such circumstances its use should be preceded by a few small and frequently-repeated doses of solution of acetate of ammonia, till the skin is rendered moist and perspirable. Pyrexia being absent,—or, if present, the skin being soft and perspirable,—the chloride should be at once commenced and persistently administered in doses of 20 grains twice or thrice daily, with strict attention to the rules above laid down as to diet, rest in bed, etc., till it no longer produces sensible effects, or till all local uneasiness, hepatic pain, and tenderness have subsided. Fomentations or hot bran-bags applied to the seat of pain in the side will be of use in aiding determination to the skin generally, as well as by their local soothing effects.

Dr. Stewart reports in the *Lancet* for October 22, 1887, typical cases of that state of the disordered liver, which, commencing in imperfect discharge of the liver-functions, when long continued terminates in congestion of the portal veins and engorgement of the vital ducts. If this stage of the disease be neglected its tendency is to terminate in subacute inflammatory reaction with marked tendency to suppuration. In this, as in other forms of tropical hepatitis, ammonium chloride would appear to be the one special remedy, and the statements of Dr. Stewart would appear to be confirmed by the statistics and cases published in his monograph.

These results of Dr. Stewart we believe are in unison with those of other practitioners. The remedy has been used in chronic torpor of the liver and chronic hepatitis to some extent in this country with asserted good results, and is referred to in such diseases in at least some of our standard treatises.

METHYLAL.

DR. B. W. RICHARDSON, in a paper read before the Medical Society of London on

October 24, 1887, continues his studies of methylal (*Medical Press*, November 2, 1887). His conclusions may be summarized as follows:

1. Methylal is hypnotic and antispasmodic.
2. Its action lies between ethylic alcohol and ethylic ether. It may be looked on as a volatile alcohol, and resembles closely pure methylic alcohol in action.
3. It can be administered by inhalation as vapor, by hypodermic injection, and by the mouth in aqueous solution.
4. It reduces arterial tension, and by local action excites glandular activity.
5. The sleep it induces is not profound unless the dose be excessive. It is quickly eliminated, and leaves no serious effects. It causes no vomiting or stomachic disturbance.
6. A fatal dose by inhalation kills by complete relaxation of the muscular fibres of the heart, leaving the heart distended with blood and the vascular organs intensely congested.
7. It combines with ether, alcohol, amyl nitrite, and many other remedial agents with which it acts in concert, while it equalizes their action by reason of its own solubility.
8. Its tendency is to maintain the fluidity of the blood, and it may, therefore, be of service in combination with ammonia.
9. It promises to yield a safe and effective anæsthetic mixture in combination with ether.
10. It reduces the animal temperature, but not to the same degree as common alcohol.
11. Used as an anodyne it passes out of the body without producing organic injury when not often repeated.
12. But, like all bodies of its class, it must be given in increasing quantities in order to keep up its effects, and it would soon yield evil as well as good by its habitual use in the community at large.

THE EFFECTS OF ANTIPYRIN ON CHILDREN IN SCARLATINA AND BRONCHITIS ACUTA.

Although the value of antipyrin as an antipyretic has been largely discussed and almost universally acknowledged, its use in the above-named diseases has been almost, if not entirely, disregarded. Can it be that the drug has not been tried in these serious ailments, which are always accompanied by a high fever? Or has the fear of collapse, which sometimes occurs, caused the physician to abstain from its use? The only use to which antipyrin has been put among children (at least the only account published) was in

whooping-cough, where small doses were recommended (*Therap. Monatshefte* for May, p. 201). The result of the experiences of DR. JULIUS FRIEDLAENDER, which appeared in the *Therapeutische Monatshefte* for August of this year, cannot therefore fail to be of interest to the profession. His experiments were on children under six years of age, suffering either with scarlatina or bronchitis acuta.

It may also be mentioned that the remedy was always willingly taken by the little patients when given in wine or raspberry syrup.

In scarlatina the drug did not seem to have any effect either on the duration of the disease (four to six weeks) or on the accompanying complications, with the exception of catarrh of the air-passages. On this it seemed to have a beneficial effect. This, when treated with antipyrin, was never severe. In every case, after taking the remedy from one to three times in twenty-four hours, in doses of .6 grm. (9 grains), the children seemed brighter, ceased gritting their teeth, and gladly took milk, wine, or bouillon, and were also willing to be freely examined, which had not been the case before. In nearly every case perspiration soon began, was followed by tranquil sleep, and in about two hours the temperature had sunk to about 38.5° C., the pulse was about 120, respiration easier and not so rapid. These results took place in some cases after a single dose of .6 grm. (9 grains), but the effects of the drug only lasted from eight to ten hours, according to the patient's age, and the dose had to be repeated once or twice in twenty-four hours. All the children (fourteen) recovered.

In one case of otitis interna suppurativa bilateralis, accompanied by extreme restlessness, gritting of the teeth, and twitching of the extremities, and with a temperature of 40.2° C., the disease being in its third week, the author was able to produce a state of "euphory," which lasted for twenty-four hours, by means of three .6 grm. (9 grains) doses of antipyrin, each dose given within thirty minutes of the other.

The patient was a little girl, aged 5. These heroic doses were repeated when the violent symptoms of the malady had again been gradually increasing for about twelve hours. The author says that he would have used the remedy again as soon as the euphory had begun to subside, but was hindered from doing so by the parents of the child, who looked upon the remedy as a "highly dangerous drug," and would not permit of its

use until the violent symptoms had again manifested themselves; then they would implore him to administer it again. He would then be forced, "for precaution's sake," to sit by the bedside until full action had taken place, which usually was in about two hours. The child recovered in five weeks after the gradual use of 1.8 grm. (28 grains) of antipyrin.

The otorrhoea, however, continued for some ten weeks longer in spite of an energetic use of "Politzer," dry cleansing, and subsequent filling up of the passage with acid. boric. pulv. (although the decomposition of pus was in a measure checked by this treatment), and the little patient, who, during her whole illness, had not spoken a word, and had only seemed to hear slightly when under the full influence of antipyrin, remained deaf and dumb.

Dr. Friedlaender states that his experience with the drug in bronchitis acuta of children has been far richer. He confesses that before he definitely settled upon the use of antipyrin he had lost many children with this disease. The duration was usually two or three weeks. Since he has used antipyrin in bronchitis of children the disease seldom continues for over a week. The author says that he must call attention to the fact that antipyrin has only proved of such great value in cases which were marked by a high fever, whereas those cases where the temperature was only moderately high (below 39° C.) were but slightly affected by the drug. From which it would appear that antipyrin is far more potent in bronchitis, when the catarrh is hindered from loosening by a high temperature.

Another peculiar fact that the author notes is that antipyrin acts far better on well-kept children than on those of poor parentage who are poorly taken care of.

Perhaps it is because the children who are well cared for are better able to stand the weakening accompanying symptoms of antipyrin. Since Dr. Friedlaender has used antipyrin in such cases which are especially suited for its use,—viz., when the temperature is over 39° C. and the patient well nourished,—all the children (thirty in number) have recovered after only a week's illness. And also among weakly children where the temperature was below 39° C. a careful use of the drug gave very good results, and the author states that he has lost far fewer patients of this class than before using antipyrin.

During a recent murderous epidemic of

bronchitis, which raged last winter in the vicinity of the author's labors in Russia, the mortality was fifty per cent. in the cases observed by himself and his colleagues. By the use of antipyrin, however, the mortality of the little sufferers was reduced to 0 per cent. among the children who came under the first category, while the mortality of the children coming under the second category (the number of which the author cannot exactly give) was, at the very highest, estimated to be only ten per cent.

The author's method of using the remedy is as follows: As soon as apathy is noticed (the temperature being usually then over 39.5°C.) he at once gives .6 grm. (9 grains) to .9 grm. (14 grains) of antipyrin in one dose. Doses of .6 grm. (9 grains) will be sufficient for children under two years of age, and its effect will last for about twenty hours, while doses of .9 grm. (14 grains) in larger children (under five years of age) will only be sufficient for about twelve to fifteen hours; therefore it will be necessary to give the last-named dose twice in twenty-four hours in order to insure the desired effect. Most of the little patients perspire freely after taking the drug, then fall into a gentle and refreshing sleep, from which they awake in one or two hours perfectly bright and happy and contented. Others, again, will improve more slowly and gradually without either sleeping or perspiring. The cough loosens; breathing becomes easier and less rapid; there is an inclination to play. In addition also the author always orders wine, food which is rich in albumen, gentle aperients, and caffeine.

R Caffeine puri, .06 to .2 (i to $\text{iii}\frac{1}{2}$ gr.);
Sod. bicarb., 1.5 to 3 (xxiv to xlvi gr.);
Aqu. foenicul., 60 (Zii);
Syr. ipec., 30 (Zi).

M. S.—Every half-hour to every two hours one teaspoonful.

In three to five days the change for the better becomes very marked. Although there is a loss of appetite, the child's cough will be much easier, its general appearance brighter, and it will be active and playful.

Usually during convalescence the author continues to give half-doses of antipyrin once a day, .3 to .45 grm. (or $4\frac{1}{2}$ to 7 grains). The children who perspire freely after full doses of the drug usually recover more rapidly than others.

"I hope," says the author, in conclusion, "that my observations may throw further

light upon the interesting actions of this new antipyretic, and especially that they may lead to further inquiries and investigations concerning its beneficial actions in bronchitis acuta of children."

CASCARA SAGRADA IN CONSTIPATION.

DR. JOHN W. FARLOW read a paper on the uses of cascara sagrada in the treatment of constipation at a recent meeting of the Suffolk District Medical Society, in which he spoke in the highest terms of the use of this remedy (*Boston Medical and Surgical Journal*, October 27, 1887). According to his experience the cases for which cascara sagrada is particularly adapted are the chronic cases, and especially those with weak digestive organs. For such cases this is far superior to rhubarb, senna, aloes, liquorice powder, and the usual laxatives, either alone or in various combinations. For acute cases its peculiar properties are not so much required, although it generally acts promptly, surely, and without secondary constipating effect. The different preparations which may be employed are the cascara cordial and solid extract and the fluid extract. Dr. Farlow generally uses the fluid extract.

It is an active and reliable preparation; the dose is small, and can be easily regulated by increasing or diminishing the number of drops taken at a time. The taste is bitter, to which some object, while others find it not unpleasant. To the latter it can be given in water or with equal parts of glycerin in water. Most of the substances supposed to disguise the taste only add a sweet to a bitter, and the combination is to many worse than either alone. The fluid extract of liquorice is perhaps as good an excipient as any. Cascara cordial has an agreeable taste, and is preferred by many. The dose is of course larger, and is not so easily regulated as the fluid extract. The solid extract is given in pill form, and consequently can be taken without the bitter being tasted. If, however, the dose in each pill proves too large, a new lot with a smaller dose has to be procured, which is a disadvantage as compared with the fluid extract.

The dose of the cordial is about a teaspoonful morning and night, or oftener. The solid extract is given in doses of 2 grains or less three times a day. The dose of the fluid extract is from 5 to 25 drops, and may be taken as follows: if the case is of long standing, and one in which many drugs have been tried, 10 or 15 drops are to be

taken in water before each meal and at night. If that does not cause one soft dejection a day, in two or three days the dose should be 25 drops four times a day, and tell the patient to take sufficient to have one dejection a day. Then, in a few days at any rate, or immediately, if he has more than one stool a day, he is to diminish the dose from 30 to 25, 20, or 15 drops, but always enough for one soft stool a day. It is better to diminish the quantity taken at a time than to lessen the number of times. It will be found that 5 or 10 drops at night often prove sufficient. It is well to omit the medicine from time to time, and it can frequently be dispensed with altogether. If necessary to resume it, let only the amount be taken that was previously found to be sufficient.

Dr. Farlow's paper evoked considerable discussion. DR. MINOT stated that he had used this remedy to a considerable extent in the treatment of constipation, always with the most satisfactory results. He had found the dose to be variable: in some cases the amount required to produce the desired action being considerably greater than in other cases, without any appreciable difference in the patients. Ordinarily he had prescribed 10 drops, which might soon be reduced after a few doses to 5 drops, and then discontinued entirely.

DR. C. P. PUTNAM only had used cascara to a slight extent: his results were variable and uncertain, a result probably to be explained by the small number of cases in which he had used it.

In reply to the question as to whether the degree of constipation which exists is in any way a guide to the dose of cascara which should be given, Dr. Farlow replied that he knew no guide to the exact amount which would be required in any case, but each patient must try the drug in a dose of moderate character, and increase or diminish the amount as the case requires. Dr. Landowski, who introduced it into France, and who experimented largely with it in the clinic of Dujardin-Beaumetz, as did also Dr. Eymeri, draws the following conclusions as to its use: The medicine purges easily, generally without colic, at a relatively small dose; its use not only does not excite anorexia, but, on the contrary, it excites the appetite, which is especially worthy of remark; at the end of ten or fifteen days of its employment, one can often stop the medicine without the constipation beginning again. If at the end of a certain time the constipation sets in again,

one has only to take the medicine again for three or four days. He thinks it particularly good in cases of intestinal atony, and, when it succeeds, he does not know of any better means of combating obstinate constipation.

CLINICAL NOTES ON SULPHATE OF SPARTEINE.

DR. J. PRIOR, docent in Bonn, prompted by the experiences of Germain Sée, has for some time past been using sulphate of sparteine as a heart-remedy in general, but found it especially useful in affections of the cardiac muscles, be it either change of tissue or weakness; further, also in valvular troubles when the compensation was affected, and particularly when the pulse was irregular, jerky, or arrhythmic. The author sums up the results of his observations with the drug in the following notes:

1. Sparteine increases the secretion of urine. This, in healthy patients and under certain circumstances, may take place without the circulation being materially affected.

2. Whether, according to the views of H. Leo, sparteine owes its diuretic property to its effect on the epithelium of the kidneys or not has not yet been proved. It is, however, very possible that the effect the drug has on the heart's action increases the quantity of urine, as the author's experiments have proved to him beyond all doubt that sparteine sulphate materially affects the pressure of the blood.

3. It must also be mentioned that, although sparteine had a beneficial effect on almost every heart-trouble, yet in several cases it had no apparent effect whatever. It acted best when used in cases of irregular compensation which resulted from valvular affections.

4. The drug usually commences to act in about two or three hours after it has been administered, and the effects last for a few hours, but in some cases even for as long as three days.

5. If the remedy has overcome the irregularity of compensation it will keep the heart's action regular for some time, as is shown in notes 12 and 13.

6. In patients where the secretion of urine has been suppressed by the affection of the heart's action, the drug will perform the double duty of regulating the heart's action and at the same time increasing the secretion of urine; the oedema and the serous transudations will also disappear.

7. The pulse frequency will be lessened,

which is explained by the heart's action having been regulated, and the pressure of blood increases.

8. It will be well to mention that also in those cases where sparteine has no apparent effect on the heart's action and has failed to regulate it, yet the pressure and difficulty in breathing was always relieved.

9. No beneficial effects were observed from the drug when used in cases of bronchial asthma.

10. On one occasion only were evil after-effects observed to follow its use, and that was after a dose of 2 grammes (31 grains). The pulse once became irregular. This was the only case where any disagreeable effects were noticed. Above all, the drug seems to have no injurious or irritating effect on the stomach or bowels.

11. Concerning the size of the dose which is necessary to insure the action of sparteine, it was found that doses of .02 (about $\frac{1}{3}$ grain) *per dosi* and .1 ($1\frac{1}{2}$ grains) *per die*, which, by Voigt, are called "medium doses," were too small. A far better action was observed when from the very outset doses of 1 decigramme ($1\frac{1}{2}$ grains) were given, and in some peculiar cases even as much as 2 decigrammes ($3\frac{1}{4}$ grains) at a dose, and in a few special cases this dose was repeated several times during the day. In this respect the author agrees with Germain Sée, and also with H. Leo, who both advise .1 doses ($1\frac{1}{2}$ grains) several times a day, and who ordered 2 or more grammes of sparteine sulphate to be taken in two or three days.

Larger doses than this should, however, be used with the greatest possible caution, as it has been observed that when over a certain amount has been given the action of the drug was reversed, and caused a still greater irregularity of the heart's action than that which had existed before the drug was used. From this fact it was, however, seen that,—

12. This artificial irregularity ceases in eight to twelve hours, and the former state again supervenes, and now smaller doses of the drug may be given with the same effect as though the drug had never been used before. From this it may be justly inferred that,—

13. No accumulative effects of sparteine sulphate need be feared.

The author considers the use of the drug indicated in all cases of heart-trouble in which digitalis, which is still the reigning cardiac remedy, has been tried without avail, or when from some reason or other its use is

abstained from, or when it is desired to regulate the heart's action in the soonest possible time.

Furthermore, the use of sparteine is of great value in stenocardiac attacks; it will give relief and good results even when the heart's action is seemingly unaffected by it.

Its diuretic action is also of great value. The author is still in doubt as to its accredited action in bronchial asthma, but, at any rate, it cannot be compared with other remedies which are used in that disease.—*Zeitschrift für Therapie*, Vienna, October 15, 1887.

THE VALUE OF CALOMEL IN CERTAIN DISEASES OF CHILDREN.

The careless and indiscriminate use of calomel properly leads to its condemnation as a remedy, but now that the cases in which its employment is indicated are being recognized with a greater clearness, we can recognize the great value of this remedy in diseases of children, especially if properly selected. DR. GEORGE B. FOWLER, in the *New York Medical Record* for November 19, 1887, refers to several affections common to children in which the greatest advantage may be expected from its employment.

Diarrhœas.—Diarrhœas in children are of varied severity, and may depend, in otherwise healthy individuals, upon several different causes,—over-feeding, improper feeding, dentition, and other nervous influences, atmospheric disturbances, and changes of temperature. Whatever the cause, the first thing to happen is an arrest of, or interference with, digestion. The food then begins to act as a mechanical irritant, or, ptomaines and poisonous gases being produced, as a chemical one, and diarrhœa ensues. Here calomel, given in $\frac{1}{4}$ -grain doses, and combined with the bicarbonate of sodium and a little sugar, repeated every half-hour, until one-half or one grain, according to the age of the child, has been administered, will, in most cases, relieve the symptoms. Of course the diet must be carefully regulated, and it may be necessary, after the bowels have moved several times as an effect of the medicine, to administer small doses of Dover's powder at intervals of two or three hours,— $\frac{1}{4}$ to $\frac{1}{2}$ grain.

Dr. Fowler believes that the remedy in this affection acts both as a cathartic and antiseptic. It relieves congested mucous membrane, and, if there be vomiting, is almost unequalled in relieving that symptom. In entero-colitis

he proposes the same plan of treatment as in simple diarrhoea, and in cholera infantum, combined with stimulants and hot or cold water enemas, as the case requires, he has succeeded in obtaining excellent results.

In all the common *derangements of digestion* where slight diarrhoea may or may not alternate with constipation, and hard balls of pale faeces are voided, Dr. Fowler gives calomel in minute doses twice a week until the bowels are uniformly loose. Then he gradually reduces the frequency of the dose, and, finally, after about three weeks, stops it altogether. For peevishness, fretfulness, anorexia, accompanied or not with slight fever, calomel is the remedy.

For *intestinal worms* the author uses nothing but this agent. In fact, whenever he desires a cathartic effect he rarely employs any other medicine than this salt of mercury.

It has long been known that calomel caused an increase of the discharge of urine, and within a year or two several papers have appeared reviving the treatment and attempting to explain its action in this connection. The writer has employed it in two cases of *pleurisy* with the best results. The urine in both instances was markedly increased, and this, together with the slight catharsis, was effective in rapidly causing absorption of the fluid. It is certainly indicated in other dropsical conditions. It is safer and more active than digitalis and acetate of potassium, to say nothing of its preference as regards taste and ease of administration. In *pneumonias* of children, where there is danger from oedema of the lung, or suffocation from accumulated mucus, calomel demonstrates its diuretic and absorbent powers by relieving these conditions and averting the danger.

Dr. Fowler is likewise a strong advocate of the use of this salt in diphtheria, and believes that it is the best remedy there is to combat this dread affection with advantage. His experience with it in this disease has been so extraordinary, so incredible, having only lost two cases out of thirty, that we can scarcely endorse his eulogy of the drug in this disease. He claims for calomel that it is the best and most agreeable cathartic for children, and that it is an antiseptic and an effective diuretic; that all will admit.

THE OIL OF TURPENTINE IN DIPHTHERIA.

The value of this drug in diphtheria and similar diseases is beginning to be universally

acknowledged, and the following results of the experiences of DR. C. ROESSE, of Hamburg, only serve to give further proof of its efficacy in this serious disease (*Therapeutische Monatshefte* for October, 1887):

During the past four years the author has treated sixty cases of diphtheria with the oil of turpentine, among which two patients were 1 year old, five were 2 years old, five were from 3 to 5 years old, ten were 6 years old, six were 7 to 9 years old, fifteen were 10 to 15 years old, ten were 16 to 20 years old, six were 20 to 30 years old, and only one patient was older than this.

Out of the sixty cases thus treated only five died. Two of these were the children aged 1 year, who were moribund when the author was called in, and died in the course of a few hours. Two of the other deaths were a little girl aged 2 and a lad aged 15. Both died after an illness of only thirty-six hours, which from the very outset had been of a most violent character. Both patients were well nourished and well cared for. The other death was that of a poorly-nourished boy, aged 15, who was also weak and poor-blooded; in him the disease lasted for five days.

Not counting the two first-named cases, there practically remains only three deaths in fifty-eight cases, which is about a death-rate of five per cent.

The oil of turpentine was given by the teaspoonful three times a day. As a corrective, Dr. Roesse used spiritus ætherus, 1 gramme (16 minims) of the spirits to every 15 grammes (4 drachms) of turpentine oil.

At the same time he gave a tablespoonful of a two per cent. solution of sodium salicylic. every two hours; also used ice-bags, and had the patient gargle frequently with a one per cent. solution of potassium chlor.

The following are the results of his observations:

1. The fever and the frequency of the pulse decreased rapidly.
2. The subjective difficulties, such as headache and difficulty in swallowing, were soon relieved.
3. The duration of the disease was greatly shortened.
4. The local symptoms ceased to grow worse in most cases as soon as the first dose of the drug had taken effect.
5. The danger of choking only occurred in one case,—viz., that of a boy 3 years old. Tracheotomy was performed, but this is the only case in which the operation was necessary.

The author abstained from painting the throat, as he contends that his experience has shown him that the practice is utterly valueless. Aside from this, the author remarks that he considers the private practice of patients painting their own throats as very unsafe, and should be carefully guarded against.

The oil of turpentine was used with the greatest possible caution in anæmic and decrepit cases, and patients with cardiac troubles.

In sound-hearted patients the increase of the heart's action was carefully watched. The author's patients were given strong bouillon or beef-tea, old port wine, and milk. The thirst was quenched with ice-water, with or without raspberry syrup.

The diet consisted only of the above-named fluids, no solid food of any kind being given.

Dr. Roesse stopped the use of turpentine oil so soon as the patient was free from fever and the local symptoms had improved. Usually 15 to 20 grammes (4 to 5 drachms) were sufficient, but in a few cases as much as 60 grammes (2 ounces) were given during the course of the disease.

The author states that he has never observed any signs of poisoning resulting from the use of turpentine oil.

Slight partial paralysis was once observed after the disease had left, but was speedily corrected by small doses of iodide.

A NEW METHOD OF EMPLOYING IODINE FOR ANTISEPTIC PURPOSES.

Antiseptic medicine—not merely preventive, but employing antiseptics as therapeutic agents in the treatment of disease, more especially of a zymotic type—is more and more becoming worthy of the attention of physicians. It will be frequently noticed that the remedies employed in the treatment of infectious diseases for the protection of those in attendance and for the prevention of the spread of infection often produce satisfactory changes in the conditions of the patients themselves. Thus, fumigation of the sick-room of a scarlet fever patient will often be attended with a marked diminution of the throat-symptoms, and with a perceptible decrease of pyrexia, restlessness, exhaustion. It appears to be tolerably well established that the most favorable period for the propagation and development of con-

tagion is in the night-time; perhaps mainly because the sunlight is temporarily withdrawn, and, the house being closed against the free transmission of air, impurities from exhalations, excretions, and various other sources accumulate. Accepting this statement as correct, it occurred to MESSRS. J. H. CASS and GEORGE BROWNEN (*Med. Press*, October 5, 1887) that if the materials employed for illuminating purposes in the night could be utilized for the evolution of a disinfectant, a useful preventive of contagion would be obtained. Koch came to the conclusion that the only effective disinfectants besides chlorine, bromine, and iodine are corrosive sublimate, osmic acid, and potassic permanganate.

We must necessarily exclude the mercurial sublimate from our consideration. Valuable, perhaps the most valuable, as it is among antiseptics for local surgical application, its highly poisonous character forbids its employment as a general medicinal disinfectant. Osmic acid and bromine are too expensive for general use, and the offensive odor of the latter would also militate against its employment. Chlorine has the same objections from the disagreeable pungency of its vapor. The potassic permanganate is also comparatively valueless unless employed in considerable strength. Iodine, however, presents none of these disadvantages. It has long been recognized by all authorities as a true germicide disinfectant. Iodoform, which acts by the gradual and continued liberation of free iodine, is now almost universally employed in the surgical application of antiseptics. The deodorizing properties of iodine have been long known, and although it has for very many years been employed for that purpose in the cancer-wards of the Middlesex Hospital, and probably in many other similar institutions, its employment as a general disinfectant has been greatly lessened, owing to the difficulties experienced in its regular and gradual vaporization. Combined, however, with salicylic acid, we find that it can be readily and permanently incorporated with fats, paraffins, or wax, and when candles made from these hydrocarbons thus treated are ignited iodine and phenol are evolved in a gaseous vaporized form. The phenol is produced by the decomposition of the salicylic acid, and its amount varies according to the temperature or rate of the combustion. Its presence may be verified by passing the vapors of the combustion through dilute nitric acid, and thus producing trinitrophenol or picric acid. But where the combustion is

rapid and complete the phenol is entirely destroyed, as all other *organic* materials, such as eucalyptus, which has been suggested for somewhat similar treatment, must necessarily be. It is not so, however, with regard to the iodine. Being *inorganic*, it is wholly volatilized and thrown out as vapor into the surrounding atmosphere, but it is in no sense destroyed. Its presence in the gaseous products of the combustion may be demonstrated by passing them through a solution of starch, or along a tube moistened with starch-mucilage. In either case the iodide of starch is speedily produced, and may be recognized by the usual tests. A very faint odor of iodine may be detected when these candles have been burnt in quantity in a close atmosphere; but this is never unpleasant, or in the least degree irritable to breathe; indeed, in several cases of asthma, spasmodic cough, and "hay-catarrh," the patients have experienced great relief from the iodine-vapor thus liberated. As a deodorizer its action is most marked; the smell of tobacco-smoke is quickly and entirely destroyed by the combustion of these candles in the smoking-room. The air of stuffy rooms and smelling closets may be rapidly purified by the same means. The odors of sulphuretted hydrogen and of ammoniacal air from a close stable have been very speedily and completely discharged by contact with the same vapor.

NOTES ON ANTIFEBRIN.

The following interesting notes on antifebrin by PROF. A. BOKAI are the results of the labors of the institute for experimental pathology of Klausenburg. They were published in the *Deutsche Medicinische Wochenschrift* for October 20, 1887, and will be of special interest to pharmacologists, as they treat mostly of the pharmacodynamics of antifebrin.

1. Antifebrin kills infusoriæ. A .5 per cent. watery solution of the drug will in a few minutes stop the movements of balantides and opalines, also of flagellates; and in fifteen minutes to a half-hour all these micro-organisms will have completely lost their motive-power. The infusoriæ of a simple infusion of hay are killed with even greater rapidity; the flagellates are here also the last to die. Antipyrin does not act any more powerfully on infusoriæ than antifebrin; the salts of thallin are more active, but the most energetic of all of these new antipyretics in this respect is kairin.

2. The moving bacteriæ (spirilli and bacilli) of an infusion of hay retain life and continue to move in a .5 per cent. solution of antifebrin as long as three hours. The antizymotic action of the drug which is claimed by Krieger, Cahn, and Hepp cannot possibly be very energetic.

3. A .5 per cent. (indeed, even a .25 per cent.) solution of antifebrin will stop the protoplasmic movements of the amœbæ in an infusion of hay in four or five minutes.

4. The amœbic movements of the colorless blood-corpuscles of rabbits cease in four to six minutes when placed in .5 per cent. solution of antifebrin containing .6 per cent. of common salt; the same result may be obtained by a .25 per cent. solution.

5. The red blood-corpuscles of man, rabbit, dog, and frog dissolve in a .5 per cent. solution of antifebrin containing .6 per cent. of salt.

When examining the solution in which the red blood-corpuscles had been dissolved (by means of the microspectroscope) it was observed that the characteristic absorption stripes or lines of methæmaglobin in the red portion of the spectrum were absent.

6. A similar salty .5 per cent. solution of antifebrin will paralyze the motoric nerve-ends of the muscles of a frog in the same manner as curare. After continued influence the striped muscular fibres lose their power of contraction entirely. The nerve-centres are not excited or affected by the above solution.

A fatal dose of antifebrin will render a rabbit helpless in five minutes; in ten to fifteen minutes convulsive twitchings begin, and the respiration becomes more and more slow and labored. If an electric current be applied directly to the muscles even an hour and a half or two hours after the drug has been administered, they will contract actively; if, however, the current is brought in contact with the motor nerves, only slight contraction will take place. At the moment of death the muscles will still contract strongly when the electric current is applied directly to them; the motor nerves, however, show no reaction.

7. Toxic, but not fatal, doses of antifebrin irritate the vaso-constrictor centre of the spinal cord and paralyze it.

8. The cyanosis, which is very great when fatal doses of antifebrin have been given, results principally from the effects of the poison on the respiratory organs; which may be explained, firstly, by a paralysis of the motor nerve-ends of the respiratory muscles; and, secondly, by a probable paralysis of

the respiratory centre in the medulla oblongata. The cause of the cyanosis in animals should never be sought in the formation of methæmaglobin, as even when the largest doses of the drug were given neither before nor after death was methæmaglobin traced in the blood. It may be added that methæmaglobin was, however, found in the blood of a dog when under the influence of doses of antifebrin which were not fatal. It is very possible that in these animals (canines) the cyanosis is accompanied by the formation of methæmaglobin, yet only accompanied and not caused by it, as also in dogs the respiratory functions are always impaired by antifebrin, even when given in only slightly toxic doses. The author is of the opinion that the cyanosis observed in man is caused by vascular spasm.

9. Antifebrin does not seem to have any effect on the brain, although it appears to affect the sensitive elements of the spinal cord. Professor Bokai asserts the above, as he has observed that in rabbits poisoned with the drug when they are still able to voluntarily move their extremities, reflex movements were impossible. The animal did not move when its tail (otherwise so sensitive) was pinched, and did not squeak when the ischiatic nerve was severed.

10. The power antifebrin has of reducing the heat of the body when given in non-toxic doses is due to its property of lessening the production of heat.

In toxic doses this is increased by the vascular paralysis; in man it is accompanied by perspiration. The author's assertion that antipyrin lessens the production of heat is sustained by the fact that the motor nerve-ends of the muscles, and also the muscles themselves, are paralyzed by the drug. Professor Bokai does not consider that total paralysis of the motor nerve-ends is necessary for the lessening of the production of heat, but holds that their partial paralysis or paresis is sufficient to hinder its production.

Such a paresis must, therefore, take place in man, when, upon taking large doses of the drug, the temperature falls with such marked rapidity.

The presence of paresis is noticeable in the weakness, adynamia, and tired feeling about which most patients who are taking antifebrin constantly complain.

In those cases of antifebrin-poisoning where, in the blood of a man or dog, methæmaglobin is found, there can be no doubt that this also will lessen the production of heat to a marked

extent. Further, the power antifebrin has of dissolving the red blood-corpuscles, if (as is not unlikely) this could take place in living blood, would undoubtedly also tend to lessen the production of heat.

Still another point should be mentioned which has led the author to the conclusion that antifebrin has the above property.

Toxic, but not fatal, doses of antifebrin, when given to a rabbit, cause a spasm or contraction of the cutaneous vessels (medicinal doses have a similar effect on a man); this lessens the giving out of heat through the skin; still, in spite of this, in a short time (both in rabbits and man) the central (rectal) temperature will be reduced. We must now also take into consideration the fact that antifebrin has little or no effect on the heart, and so in this case the fall of temperature is clearly due to the lessening of the production of heat.

That this is really the case will be made apparent by the following brief account of two of the author's experiments:

A dog was put under the influence of tincture of opium (per venam) and then tied down by his four legs in a room the temperature of which was 20° to 23° C. Professor Bokai then placed a thermometer under the skin of the lower part of one of the hind legs, and placed another between the muscles of the other hind leg, and still another in the rectum. After the normal temperature as indicated by each thermometer had been carefully determined, the author introduced into the stomach of the dog a large, although not fatal, dose of antifebrin, and for the next four hours proceeded to carefully record every change of temperature of each thermometer. The table which he had thus procured he carefully compared with another table of the temperature of a canine which had been similarly prepared, but which had not been given antifebrin. The comparison showed that in the animal which had not been treated with antifebrin the temperature under the skin sank 4.2° C. in four hours, the temperature between the muscles sank 2.3° C., and in the rectum 2.1° C., while in the dog that had been given antifebrin the temperature under the skin sank 4.4° C., in the muscles it sank 4.5° C., and in the rectum 4.6° C. It will be observed that in both animals the fall of the temperature under the skin was nearly uniform; the temperature of the muscles, however, sank 2.2° C. lower in the animal treated with the drug, and the temperature of the rectum of the same animal

2.5° C. lower in a like period than in the dog that had not been given the drug.

Should the temperature of the skin after a time have indicated a rise, then the great reduction of internal temperature could be easily explained by the giving out of heat through the skin. As this was not the case, and especially as we observed such a rapid fall of temperature, the cause can only be explained by the lessening of the production of heat in the muscles.

Finally, the author concludes by stating that a student in his institute, Mr. Emanuel Deutsch (*Cand. Med.*), has been making a series of experiments relative to the effect of antifebrin on the nitrogen contained in the urine, and has found, as might have been expected, that antifebrin has the power of greatly decreasing the quantity of nitrogen in the urine. Mr. E. Deutsch is working according to the "Kjeldahl" method, and his observations will be shortly published.

ARSENICAL PIGMENTATION IN PEMPHIGUS.

At a recent meeting of the Clinical Society of London, DR. HANFORD reported a case of pemphigus occurring in a child aged 13, and terminating in complete recovery after nearly a year (*Medical Press*, October 19, 1887). The limbs, trunk (except parts of chest and abdomen), face, tongue, mouth, pharynx, mucous membrane of nose, conjunctivæ, and orifice of the vagina were all affected. The eruption came out in crops, and was accompanied by rise of temperature. Micro-organisms were found in the bullæ which contained pus, but not in those which contained serum. Quinine in large doses was given with benefit, and arsenic. Of the latter, 15-minim doses of Fowler's solution were given thrice daily, and continued for ten weeks. After this, the skin of the whole body was noticed to be dry, brawny, and darkened in color. The axilla, groins, and abdomen were almost as dark as in Addison's disease. The skin looked dirty, but the color was proved to be due to pigment, deposited chiefly in the rete, but partly in the more superficial epithelium. The arsenic was stopped, and the patient treated by wet-packing, and in a month the skin had resumed its normal, smooth, moist appearance, and much of the pigmentation had disappeared. Also on the hands and feet there were many elongated patches of cicatricial-looking skin, thickened and elevated. These

patches were covered with white points, like millet-seeds, just beneath the epithelium, and resembling, to the naked eye, miliary tubercles. They were not tubercular, but consisted of accumulations of degenerating epithelial cells in the deeper part of the epidermis. They disappeared in four or five months. It is possible that this condition also was due to the arsenic. Several colored drawings and photographs illustrating these conditions were exhibited. A third case of pemphigus was described, in which there was some ground for suspecting implication of the mucous membrane of the intestinal canal. It presented also the atrophied glossy condition of the skin of the hands mentioned in the first case, and which is so suggestive of an implication of the peripheral nerves. No definite affection of sensation or of the reflexes, however, could be discovered, though reference was made to the statement of Dr. Pasquale Ferraro that he had found advanced changes of an atrophic degenerative nature in the posterior horns of the dorsal spinal cord, and also in the peripheral nerves, the ganglia on the posterior nerve-roots, and in the sympathetic ganglia. Two further instances of arsenical pigmentation were narrated, and the opinion was expressed that small doses of arsenic— $\pi\lambda v$, or $\pi\lambda x$ —of the liq. arsenicalis repeated thrice daily for about two months were capable of producing a pigmentation of the skin, chiefly of the abdomen, lower part of chest, lumbar region of the back, axilla, groins, and inner part of the thighs. This condition was not necessarily accompanied by roughness and dryness of the skin, and disappeared slowly in from one to four months, or rather longer.

DR. CROCKER, referring to the pigmentation of the skin, said that this was fairly common on the site of eruption, as a result of the treatment of psoriasis by arsenic. General pigmentation, however, was less common, but did, nevertheless, occur from time to time. He had then under his care a boy with a bullous erythema, which he was treating by arsenic. Latterly the boy's skin had become pigmented. He thought it should be generally known that pigmentation was likely to follow prolonged treatment with arsenic, quite independently of the eruption. It was probably due to a deposit of the metal itself in the skin. The pigmentation lasted a very considerable time, much longer than four months, as mentioned by the reader of the paper.

DR. GOODHART took up the question of

fever mentioned by the reader of the paper, he having a case now under his notice, in a little girl, in which high fever occasionally occurred. He said that this case showed very plainly the peculiar property of arsenic to control the disease, though not to cure it. In this case the dose of arsenic required to subdue the eruption was so high that it could not be continued, and then the eruption recurred.

SIR DYCE DUCKWORTH wished to add his testimony as to the value of arsenic in the treatment of pemphigus. He had formerly been sceptical as to the benefits claimed for its use, but had more recently had ample proof of its efficacy, several cases having been apparently quite cured thereby. In one of these cases marked pigmentation had followed the use of 12 minims of arsenical solution three times a day.

THE ACTION OF CHLORIDE OF ETHYLENE ON THE CORNEA.

In the *France Médicale* of July 5, 1887 (*London Med. Record*, October 15, 1887), MM. R. DUBOIS and L. ROUX publish the results of their researches on the action of chloride of ethylene on the cornea, which was the subject of a communication to the Academy of Science.

The interest of these researches lies principally in the very experimental opacification of both corneas, under influence of an agent administered through the respiratory organs. The animals experimented upon were dogs, that were made to inhale the vapors of chloride of ethylene for one hour and a half. The eyes presented nothing particular, except a considerable diminution of intraocular pressure and an irregular astigmatism already noticed by M. Dubois in prolonged action from chloroform-anæsthesia. With anæsthesia by chloride of ethylene these modifications are much more apparent.

The cornea remains transparent as long as the inhalation continues, and afterwards as long as the animal throws off by the lungs the anæsthetic. But after from sixteen to eighteen hours, sometimes less, the two corneas lose their transparency, take a bluish opalescent tint, and give a peculiar expression to the animal. On the two dogs in question this strange effect took place during the night, and was first observed in the morning on their awakening. No other disturbances were observable. The inhalator had been so arranged

that the anæsthetic vapors could have no direct contact with the eye.

One of the animals was killed, the other kept under observation for a fortnight. Both presented the same symptoms. In the living dog the tension of the eyeball was still considerable, although less than the first days. The maximum of intraocular tension was attained at the moment of the production of the corneal opacity.

The curvature of the cornea was evidently exaggerated, principally along the vertical meridian, causing a regular astigmatism, easily appreciable with the disk of Placido. At the moment the opacity of the cornea was first noticed there was no trace of irregular astigmatism; the surface of the cornea had preserved its polish, but examined through a magnifying-glass, very numerous minute depressions were observable all over it. The general aspect is that of total anterior staphyloma, opaque and symmetrical in both eyes. Vision subsists, but is rather dimmed by the opalescence of the cornea. The ophthalmoscope shows that the crystalline lens is still transparent, but the details of the back of the eye are not distinguishable. The oculo-pupillar reflex is retained, and also the oculo-palpebral reflex. The sensitiveness of the cornea and of the retina did not appear to have been affected. For the last two days there is amelioration in the state of the cornea. At the outset the opacity was uniform, but at present, under the ophthalmoscope, with a strong light, numerous whitish arborisations are discernible, the direction of which radiates from the periphery towards the centre.

The experiments of M. Ranvier at the Collège de France on the cornea of animals used for experimentation having shown that the cornea may lose its transparency when subjected to pressure, it is not impossible that the variations of intraocular pressure noticed may be the cause of the opacity produced in the living animal. The question arises whether in this case it is not a dishydration of the cornea, more particularly of certain constituent elements of that membrane, the more so that M. R. Dubois has already proved the powerful dishydrating action of anæsthetic vapors on animal and vegetable tissues. What seems to confirm this view is the remarkable loss of weight of the animals experimented upon, unexplainable by an increase of the phenomena of assimilation or by refusal of food. These observations are most interesting, and augment the list of those so little understood accidents which so

suddenly supervene at the moment when the economy is getting rid of poison, and which differ so entirely from those produced by the penetration of the poison into the system.

USTILAGO MAYDIS AS AN OXYTOCIC.

During the months of May to August, 1887, DR. W. A. N. DORLAND, while serving as a resident obstetrician in the Philadelphia Hospital, tested the efficiency of ustilago in those cases in which the parturient pains had almost or entirely died away during the second stage of labor, and he reports nine cases in the *Medical News* for November 5, 1887, grouping his conclusions from them as follows:

1. *The toxicology and physiological action of the drug.*

No cases of poisoning in man by the drug are on record. That it is, however, possessed of toxic properties in large doses has been proved by Mitchell. (See THERAPEUTIC GAZETTE, 1886, p. 223.) He found that in the lower animals, in large doses, it acted violently upon the spinal cord, paralyzing first the sensory, later the motor, tracts, finally involving the motor and probably also the sensory nerves. Like ergot, then, it is probable that the chief force of the drug, in toxic doses, is expended on the nerve-centres, producing a toxic paralysis.

After the administration of the drug in three instances, there was considerable nausea, followed by vomiting of the ustilago, together with the other contents of the stomach. This nausea seems to be of a similar character to that produced by the ergot of rye, and calls for no further discussion.

The action of ustilago upon the uterus has been more carefully noted. After the ingestion of a sufficient amount, in from twenty minutes to half an hour, the pains, if present, are increased in severity, in frequency, and in duration, presenting a marked clonic character, following each other in frequent succession, with a decided intermission between each. In this respect it differs decidedly from the action of ergot, which, in full doses, produces one continuous, tonic spasm of the uterine muscle. It is this property of ergot which has, when administered before the delivery of the placenta, produced in so many instances the irregular contractions of the uterus, of which the hour-glass is a well-known example. The employment of ustilago

seems to be entirely free from such unpleasant complications.

In addition to being a valuable adjuvant in stimulating weak uterine contractions, ustilago seems to possess the property which some years ago was ascribed to quinine,—namely, of exciting uterine pains when entirely suspended. This has been noticed by Leonard and others.

As to the time required for the action of the drug to become apparent, it may be said that it differs in different cases, depending, undoubtedly, upon the rapidity with which it is absorbed from the gastro-intestinal tract and carried into the system. In the above record, in only two instances did it require over thirty-five minutes before the ustilago acted upon the uterine tissues, and in the latter case it will be remembered that most of the drug was ejected by emesis. In the remaining seven cases the average time required was twenty-five minutes.

The effect produced by ustilago upon the other unstriped muscular tissues of the body has not been inquired into. Probably it produces the same increase of intestinal peristalsis and the same rise in the arterial pressure, due to vaso-motor spasm, as is produced by ergot. This is yet open to investigation.

2. *The indications for the employment of the drug.*

It may be noticed that in all the above cases the ustilago was not administered until complete dilatation of the os had been accomplished. Whether or not a disastrous effect would be produced by the administration of the drug prior to the commencement of the second stage of labor cannot be stated. As yet, that question has not been decided. From the study of the physiological action of ustilago, it would appear that all danger of the irregular contractions of its compeer, the ergot of rye, would be precluded, and that if there were any possibilities of the exigencies of the case demanding its use, it might be employed with impunity during the first stage of labor. At present, however, it seems that the first indication for its use is the failure of the pains, with *complete dilatation of the os uteri*.

In none of the cases was the drug employed until the pains of labor had either become so weak that they were inefficient to accomplish the expulsion of the fœtus, or until they were entirely suspended. This, then, the author considers the second indication for its use,—namely, the *inefficiency or entire suspension of the parturient pains*.

After the ustilago had been taken, it may also be noticed that in no case was there the slightest tendency towards a post-partum hemorrhage. In each case, after the expulsion of the placenta, the uterus remained in a state of firm contraction. While during the three months the great majority of the remaining cases, in which the customary ergot had been employed, showed no tendency whatever towards this alarming accident, however, in two instances was there such an occurrence demanding prompt attention. The third indication, then, for the employment of ustilago is claimed to be *a condition of uterine inertia threatening or producing post-partum hemorrhage.*

3. *The dose and mode of administration.*

The preparation of ustilago employed in all reported cases was a good fluid extract. The dose of this varies from $\frac{1}{2}$ to 2 drachms, 1 drachm being a fair average. This may be repeated at intervals, as required. Should it be necessary, it may be used hypodermically, in doses of from 5 to 15 minims.

Finally. *The advantages of ustilago over ergot.*

Dr. Frank H. Potter, in a paper on the "Proper Use of Ergot in Obstetrical Practice," closes his article with a series of ten conclusions. In these he states that when administered during labor the action of ergot is uncertain, producing irregular contractions, rigidity of the os, with interference of the placental circulation, or too rapid expulsion of the fœtus, jeopardizing the maternal tissues. He also asserts that the life of the child is endangered through absorption of the oil of ergot, and that indirectly the drug may prove a cause of puerperal septicæmia by preventing the removal of every portion of the placenta and membranes. His last conclusion is as follows: "The proper use of ergot in obstetrical practice is limited to those cases in which, after the expulsion of the placenta, the uterus refuses to contract, or, having once contracted, shows a tendency to secondary relaxation. Even in these cases reliance should not be placed upon it alone, but its action should be supplemented by the other means used to provoke uterine contraction."

When compared to this formidable array of objections, the employment of ustilago seems much to be preferred to that of ergot. It does not produce irregular contractions, with all the consequent complications and sequelæ; containing but two and a half per cent. of fixed oil, while ergot contains from

twenty-five per cent. to twenty-eight per cent., the dangers of absorption are reduced to a minimum; and, finally, as it can be procured at a cost of fifty per cent. less than that of ergot, it seems to be on a fair highway towards the supplanting of the latter in obstetrical practice, should the results of the investigations thus far be confirmed by subsequent researches.

THE SURGICAL TREATMENT OF PERITONITIS.

The propriety and value of surgical intervention in the treatment of certain forms of peritonitis formed the main subject discussed at a late meeting of the London Clinical Society. The cases which gave rise to the debate belonged to two different categories, and perhaps for that reason the discussion was rather involved. It may therefore be convenient to analyze it on each head. In his successful case of acute suppurative peritonitis, MR. BARWELL was pursuing the practice which was brought before the notice of the Royal Medical and Chirurgical Society by Mr. Treves and Mr. Marsh two years ago, giving rise to an interesting debate on the occasion. For although, as Mr. Barwell said, the priority in conception of this procedure rests with the late Mr. Hancock, the operation itself, with the deliberate intent of treating the peritoneal condition, was first performed by Mr. Treves. It may now be considered not only a legitimate but a very valuable means of treatment, and one which is sure to become more widely practised. Mr. Barwell's case was also instructive, as the President pointed out, on account of the large accumulation of gas present within the abdominal cavity; which makes it more than likely that the peritonitis had been excited by a perforation of the bowel, perhaps of the vermiform appendix. General peritonitis due to perforation is almost invariably fatal, so that physicians may be justified in having early recourse to the aid of the surgeon, who by incision and drainage can promise a more favorable issue. As to the *technique* of the operation, nothing can be simpler, and it was clearly shown that no better medium for washing out the cavity could be employed than pure water, provided this were supplied in sufficient amount, and the irrigation were as thorough as possible. At the Clinical Society more attention was bestowed upon the subject of tubercular peritonitis, the two cases furnished by DR. KNAGGS and MR. CLARKE, of Huddersfield, forming

the chief topic of the debate. Here we may remark how deep-rooted is the notion that tubercular disease of a serous membrane like the peritoneum is necessarily fatal, and the impression conveyed by Dr. Burney Yeo's questions was certainly to that effect. We may refer all those who still hold to this opinion to a clinical lecture on "Tubercular Peritonitis in Children," by Dr. Gee, published six years ago (*The Lancet*, January 1, 1881), and his statement that "recovery from tubercular peritonitis is common" will be endorsed by physicians who practise in children's diseases. In adults cases of recovery from this disease are less common, but Sir Spencer Wells's celebrated case is a standing refutation of the prevalent pessimistic views which would regard tubercular peritonitis as being as hopeless as cancerous. The debate, however, did good service not only in correcting this impression, but in showing how materially recovery is aided by draining the cavity of its contained fluid. Here, again, a lesson may be learned from the practice often adopted in the case of children with considerable success,—viz., simple paracentesis. Whether irrigation and continuous drainage is superior to paracentesis, which may have to be repeated, experience alone will show; but that the essential thing is to withdraw the fluid so as to allow the affected serous surfaces to come into contact was strikingly brought out in the report which Mr. Treves gave of the recently recorded experience of German surgeons. The measure of success obtained did not seem influenced by the adoption of various methods; the essential point was that the peritoneal sac should be laid open. It would thus appear (as was suggested in the debate) as if the effused fluid were itself a source of danger; but that it is absolutely necessary to "alter the character of the inflammation" by the injection of iodine, carbolic acid, or other irritants is still an open question. Dr. Knaggs and Mr. Clarke are to be congratulated on the result of their bold treatment, which may well be adopted in similar cases uncomplicated by active tubercular disease of the lung or ulceration of intestines. Such cases in the adult are not so very common, and their diagnosis is not always simple; but that the local tubercular process may be quite arrested and the general condition of the patient vastly improved by local drainage (aided, of course, as Mr. Parker pointed out, by general treatment) has been amply shown.—*The Lancet*, November 5, 1887.

EGYPTIAN TAMARIND FOR HEMORRHOIDS.

In the *Medical and Surgical Reporter* for November 12, 1887, Dr. J. C. BROBST calls attention to the use of Egyptian tamarind for bleeding hemorrhoids, and states that in his practice he has had most extraordinary demonstration of its curative powers in many cases which had been by others deemed incurable. He employed the decoction of the tamarind flower in doses of 3 or 4 wineglassfuls, but unfortunately, however, he does not give the quantity of the drug used for making this preparation. After the use of this drug he states that the itching and burning become gradually relieved, and where the affection is complicated, as it usually is, with constipation and a loss of appetite, the good results are especially marked.

NOTES ON THE PHYSIOLOGICAL AND THERAPEUTICAL ACTIONS OF SOLANIN.

According to Clarus, solanin is a narcotic poison which has the property of paralyzing the spinal cord and vagus endings, and of exciting the peripheric nerves.

In former years Geneuil experimented with the drug, and came to the conclusion that solanin exerted its narcotic properties on the medulla oblongata, spinal cord, and nerve-branches, and thereby caused a paralysis of the extremities and of the sensitive and motoric nerves.

CAPPARONI had recently conducted a series of experiments with solanin on man. His results are as follows:

A very small dose of solanin (.10 grm. = 1.54 grains) will cause (especially in individuals with a sensitive stomach) a sensation of burning in the stomach, salivation, and nausea. All these symptoms prove that the drug causes a local irritation. When the drug is given where the stomach has been previously anesthetized, or when it is administered hypodermically, this irritation does not take place.

The same dose causes a lessening of the pulse's frequency and of the respirations, and a decrease of the reflex activity of the excitomotor tendency of the spinal cord and medulla oblongata.

Solanin does not seem to have any influence on the brain-centres; it is not a hypnotic; the pupils do not undergo any change.

In the circulatory system small doses of solanin lessen the rapidity of the heart's ac-

tion and increase the pressure of blood in the arteries.

Toxic doses, however, cause the pulse to increase greatly, and lessen the arterial pressure, and also increase the respirations. Solanin is thrown off by the kidneys, but has no effect on the secretion of urine, neither is it a diaphoretic.

As to its therapeutical actions, the author has found it of great value in cases where it was necessary to reduce the irritability of the spinal cord; also in asthma, in difficulties in walking, and muscular spasms of a peripheric origin, in tremor, etc.

The author usually gave .15 to .30 grm. ($2\frac{1}{2}$ to $4\frac{3}{4}$ grains) daily, divided into a lesser or greater number of doses, according to the special needs of the case.—*Zeitschrift für Therapie*, Vienna, October 15, 1887.

AN ANÆSTHETIC COMBINATION OF CHLOROFORM AND OXYGEN.

In a recently published paper on oxygen in chloroform-narcosis, DR. KREUTZMANN, of San Francisco (*London Med. Record*, October 15, 1887), states that the use of a mixture of oxygen and chloroform for anæsthetic purposes was first recommended by Neudörfer, of Vienna, who anticipated that such a mixture would, on inhalation, cause speedy insensibility without excitement, and be absolutely safe and free from the bad results of the ordinary anæsthetic agents. This recommendation, although Neudörfer's first trial was attended with the best results, has not been followed in consequence of certain difficulties in obtaining by the original method the required mixture of gas and chloroform vapor. Kreutzmann has given up all endeavor to supply the chloroform in fixed doses according to Neudörfer's directions, and now, in order to administer the mixture in an efficient manner, he attaches, with the intervention of an exhausting pump, an elastic bag containing oxygen to Junker's chloroform apparatus. In this way oxygen in the place of atmospheric air is pumped through the chloroform, and the patient inhales oxygen impregnated with chloroform vapor. It is pointed out that some air is taken in at the same time, as it is impossible to exclude this by the mouth-piece.

Dr. Kreutzmann speaks very favorably of the results obtained from the use of this mixture in twenty-three operations of different kinds, performed by Dr. Morse, of San Francisco, on patients of both sexes and varying

in age from seven to fifty-six years. In every instance the anæsthetic acted with extreme rapidity, and repeatedly after a few deep inspirations such a degree of anæsthesia was attained that pain was no longer felt, although reflex action was still maintained. In cases in which deeper narcosis was required further administration of the mixture always removed any tendency to struggling. Children and young subjects were rendered insensible in a remarkably short time, but with drinkers the administration lasted longer. In not a single case was any marked excitement observed. With slight anæsthesia no change took place in the pulse and respiration. In instances of deep narcosis the respirations were accelerated and the pulse-frequency was diminished. In many patients the face became congested and covered by perspiration. After a state of incomplete anæsthesia the patient "came to" at once when the inhalation of the mixture had been arrested, and after a more prolonged and deeper narcosis there was for some time a quiet sleep, which, however, did not resemble in any way the deep coma observed after the administration of ether or of pure chloroform. Invariably the patient in recovering from the effects of the anæsthetic became conscious at once, and did not suffer subsequently from headache, vomiting, or nausea. Whether death from chloroform may be avoided by practising this mode of administration remains to be determined by further and more extended experience, but the small quantity of chloroform that is thus used, and the almost complete absence of any subsequent bad effects, permit us, Dr. Kreutzmann thinks, to entertain the best hopes in this respect.

HYDROGEN SULPHIDE IN ASTHMA AND CHRONIC BRONCHITIS.

DR. BATTISTI (*London Med. Record*, October 15, 1887) has experimented upon patients affected with chronic bronchitis and asthma. He finds that his patients, after absorbing during three months, twice a day, monosulphide of sodium, have experienced neither the least disgust nor slightest irritation of the stomach. He proceeds as follows: Lehmann having shown that the absorption of carbonic acid by the stomach is easier when fasting, Dr. Battisti prescribes the ingestion of sulphurous water fasting, or four hours after meals. In order to avoid repugnance he uses the following formula: Monosulphide of sodium, 1

gramme ; distilled water, 500 grammes. One teaspoonful of this solution contains one centigramme of the monosulphide, and he gives 1 or 2 spoonfuls a day, according to the toleration by the patient, which is equivalent to about one litre of Eaux Bonnes water. Calculations based on the chemical equivalents of monosulphide of sodium and of carbonic acid show that one-quarter of a litre of this gas is sufficient to entirely decompose one gramme of monosulphide. The patient, therefore, takes 1 teaspoonful of the sulphurous solution, and immediately afterwards 1 soup-spoonful of Rivière's potion, or a glass of seltzer water. Rivière's potion is preferable on account of its lesser volume. Dr. Battesti has obtained the best results with this treatment, without its producing any disgust or irritation to the patient.

Reviews.

TEXT-BOOK OF THERAPEUTICS AND MATERIA MEDICA.

By Robert T. Edes, A.B., M.D.

Philadelphia : Lea Brothers & Co., 1887.

When it was announced that a new work on therapeutics was about to appear from the pen of Professor Edes, we looked forward with much eagerness to the expected addition of a new American classic to the already long list of therapeutic treatises, and thought that perchance the well-known volumes of Bartholow and of Wood would be superseded by a fresher and more learned rival. The eagle seems, however, this time to have plumed its feathers for a very lowly flight, and instead of a classic, we are astonished to find that the late professor of Harvard University has written a small book which bears the same relation to a full treatise on therapeutics that a two years' medical course does to a three or four years' curriculum. The work is a sort of primer of the subject, which may be useful for students to cram from, but can be of but little value to any one who desires to thoroughly study the most important of all the branches of the science and art of medicine. Perhaps we can convey our idea of the aims of the book by stating that it should be classed as a modern representative of Biddle's *Materia Medica* and of Neill and Smith's *Compend* of a still earlier generation. Of course a reviewer cannot be expected to waste time in reading through an elementary book like the present. He is justified in taking out a few articles and from them judging the rest. We primarily selected the

article on digitalis as a specimen article. We find that the whole subject of physiological action and therapeutic use of this remedy is discussed in about a page and three-quarters, and even the terse, dogmatic statement of effects in this article is so out of concord with the teaching of most leading physiological therapeutists of the day, that it is of the highest importance that the author should elaborate the page or two into a long article and demonstrate the correctness of his views. That "digitalis finally causes the paralysis or exhaustion of the heart and of the vaso-motor system and death by paralysis of all cardiac nerves," is certainly open to challenge. The statement, "The change from the strong to the weak pulse may take place suddenly, especially on exertion. This is spoken of as the cumulative action. It does not, however, imply any actual accumulation of the drug in the body," is also at variance with our own experience and with the teachings, we think, of other therapeutists of authority. The so-called cumulative action of the drug is not the sudden change from the strong to the weak pulse, and does, to our thinking, apply an actual accumulation of the drug in the body. As an instance of what is really meant by the cumulative action we may cite a case from our experience of a patient with excessive effusion in the pleura who had been taking digitalis for some weeks without sensible effect, when one morning the pulse suddenly dropped from about 90 to 70; the next day the pulse was 60, then 50, then 40, the beats remaining strong and full. This sudden excessive action almost invariably develops when there has been no diuretic action of the drug, and is not rarely seen after tapping for ascites when digitalis has been previously given steadily for a length of time. Under these circumstances the obvious explanation is that the digitalis has been long in the serum throughout the body, and that the withdrawal of large quantities of the fluid from the abdomen by tapping, and the consequent removal of the pressure from the outside of the blood-vessels, causes a relaxation of those blood-vessels, which is followed by a rapid absorption of serum with its load of digitalis, so that at once a very large amount of the poison is precipitated upon the heart. We also notice in this article on digitalis the statement that "the digitalin of the last edition of the *Pharmacopœia*," etc. There is no such thing as the digitalin of the last edition of the *Pharmacopœia*, this preparation having been dropped out at the last revision.

There is such a demand for short-cuts to knowledge in America and for cram-books that we have no doubt the work of Dr. Edes will sell, but we do not think that it will add to its author's reputation.

SEXUAL IMPOTENCE IN THE MALE AND FEMALE. By Wm. A. Hammond, M.D., etc.
Detroit, Mich.: Geo. S. Davis, 1887.

The history of human depravity is by no means pleasant reading, but, perhaps, it is necessary to the understanding of certain cases, if their cure is to be sought. Perhaps, too, a writer dealing with such topics is all the better for the absence of prudery, and a business, matter-of-fact manner. Still, if ever a book deserved the seclusion of lock and key this production certainly does. The histories, as given by Dr. Hammond, are certainly graphic, and his devices for the cure or amelioration of these moral monsters are ingenious; but the thought cannot but arise whether it is worth while to attempt any relief for some of them, and whether the physician who aids them in avoiding nature's relentless punishment is not condoning crime and almost an accessory after the fact. The book is easily written, and admirers of "Lal" will recognize the author's characteristic style more readily here than perhaps in more erudite works like his treatise on nervous diseases. Some valuable ideas, too, can be gathered from these pages, which tend in the direction of rational treatment, and the adaptation of special means and special ingenuity to special cases, for Dr. Hammond follows no beaten track if he knows it. From what we have said above, the reader may infer that "sexual impotence" is by no means a work for promiscuous reading; in fact, it is about the most dangerous one for such a purpose with which we are acquainted. This, however, is inseparable from the nature of the task that the author has undertaken, and we commend the work to those whose special pursuits lie in the direction of those diseases and conditions which nature has entailed upon the vicious for the best of purposes, and which man should not entirely relieve even if he could.

E. W. W.

THE DETERMINATION OF THE NECESSITY FOR WEARING GLASSES. By D. B. St. John Roosa, M.D., LL.D., etc. Physician's Leisure Library.
Detroit, Mich.: Geo. S. Davis, 1887.

The ignorant physician, ignorant of the cunning art of the oculist, may search many primers and handbooks for advice on the topic discussed in this book. He will gen-

erally be disgusted, and conclude that if the specialist has any really valuable hints to give him, the fear of trusting him too much, and of lifting the veil of the oculistic Isis too high, has deterred him from revealing them. There is only one way that will occur to him, —*i.e.*, to study the specialty himself, and "become as gods," knowing all about it, as well as his teachers. Dr. Roosa, however, has something to tell, that he tells without fear of rivalry, and has produced the most useful monograph which we have yet seen. By reading it carefully, and getting this simple and cheap apparatus that he recommends, one can without an excess of knowledge decide pretty readily as to any necessity for sending his patient to the higher powers. He also has the good old-fashioned way of talking plain English, and when he uses technical terms he explains them, so that the explanation explains, and is not, as so often, worse than the problem. We think the trifling cost of this book will be money well expended by any one in the profession and in Cimmerian darkness on the subject, that so many are in, who will buy it and read it until its contents are familiar.

E. W. W.

CYCLOPÆDIA OF OBSTETRICS AND GYNÆCOLOGY. Vol. VI. and Vol. VII. A Handbook of General and Operative Gynæcology. By Dr. A. Hegar and Dr. R. Kaltentbach. In two volumes, Vol. I. and Vol. II. Edited by Egbert H. Grandin, M.D., etc.
New York: Wm. Wood & Co., 1887.

The value of the Cyclopædia becomes more evident with the issue of each succeeding volume. Of the two before us, Vol. VI. of the series contains sections on gynæcological examinations, minor therapeutic manipulations and elementary operations, and operations on the ovaries. The discussion of anæsthesia as used for examinations is interesting. The author prefers ether. The directions given for the various procedures are simple and intelligible. Everything necessary is well illustrated by good wood-cuts. As regards dilatation of the urethra to admit the finger, we find the author expressing the idea that patients, after this method of exploration has been employed, "are not secure against permanent incontinence." In regard to specula and the methods of using them, we find little or nothing novel or original. Cervical dilatation the author produces by "solid, bougie-like instruments of unchanging size." The author's are of hard rubber, cylindrical, not conical like those of Tait, but with conical tips. The diameters increase

from two millimetres by degrees of one millimetre. Eversion of the rectum is recommended for inspecting the lower part of the anterior rectal wall ; for the rest specula are needed.

Accidents following the use of vaginal injections are attributed by the author to all forms of instruments, but less to the irrigation than to the rubber compression syringes. Many accidents are not easily explained. The uterine syringe, if used with care, is not entirely abandoned. The canal should always be somewhat dilated previous to their use. Irrigation of the uterine cavity is considered a valuable therapeutic agent.

Pessaries are considered as a necessary evil. Everything possible to benefit the existing condition should be done before their introduction. Abdominal belts are recommended for a certain class of cases. Studley's double ring pessary is described, along with many other new and rare instruments. Tampons, local abstraction of blood, and artificial impregnation are discussed. Of the latter procedure he says very truly that so many causes not requiring it may be found as the real factors in the causation of sterility that but little remains for artificial impregnation to do ; it may be employed in stenoses, especially flexion stenoses in the upper part of the cervical canal. "Every physician," he says, "will probably experience a feeling of disgust at being concerned in such procedures ;" "but there are motives" which may overcome such feelings. A more important matter than mere squeamishness is the extreme doubtfulness of a successful result. The spermatozoa are so fragile that their mere transfer to a syringe may result in their heads becoming separated from their tails. In order to win in this game both heads and tails are required, it seems. Massage in gynecology is discussed pretty exhaustively, and the author concludes that its results are by no means very valuable. General and special operative procedures occupies the remainder of Volume VI. There is an excellent section on the prevention of surgical infection, and the subject of ovariectomy finishes the volume.

The second volume contains operations on the tubes, broad ligaments, and vagina ; operations in urinary fistulæ, prolapse operations, and operations on the vulva and perineum. The whole subject of the disease of the tubes, and operations for their relief and cure, is so new, and is exciting so much interest, that on that account, if no other, the present volume will be eagerly sought and

studied. All that illustration can do will be found here, and the various operations and modifications of operations are minutely and clearly described. E. W. W.

A SYSTEM OF GYNÆCOLOGY BY AMERICAN AUTHORS. Edited by Matthew Mann, A.M., M.D., etc. Vol. I. Three colored plates and two hundred wood engravings.

Philadelphia : Lea Brothers & Co., 1887.

"Gynæcology," the editor tells us, "has now grown to an extent which requires for its thorough treatment the co-operation of representative men." Growth of Western towns and cities pales before the achievements of gynæcology,—twenty years ago nameless, to-day full-grown. In these few years we have witnessed the development of a science ; is it possible, asks the observer, for another score of years to give us another equal increment ? Will not research and daring exhaust the field ? Will not subdivision and specialism reach ere long their ultimate atoms adamant and indivisible ? Has not the field been exhausted by the reaper, the gleaner, the very birds of the air, and have we not, in reaching the microscopic stage of investigation, neared the end ?

Dr. Mann, in any case, has done us a service. If this be almost a completed science, then he has gathered it together in one perfected whole, and his work will be all the better appreciated.

The excellent historical sketch of gynæcology, by Edward W. Jenks, M.D., opens the volume. There is shown its progress from Hippocrates till to-day,—progress very slow and tortoise-like for centuries, then very rapid and electric for the past few years. As for its further progress, in reading the flood of literature it evokes one is struck with the universal sameness of the material, and the vast efforts made by the writers to strike out new paths, efforts by no means always successful.

"The Development of the Female Genitals," by Henry J. Garrigues, M.D., "The Anatomy of the Female Pelvic Organs" by Henry C. Coe, M.D., follow the opening chapter. Dr. Coe has given a very minute, elaborate, excellently-written and profusely-illustrated article. It is by no means dry and unsuggestive, but filled with practical remarks, like a running commentary. "Malformation of the Female Genital Organs" is another excellent article by Dr. Garrigues. "Gynæcological Diagnosis," by Egbert H. Grandin, M.D., marks the commencement of the truly practical part of the book. Here we are introduced to all the many instruments

and varieties of instruments which Smith has appropriated and Jones modified for diagnostic purposes. Good wood-cuts delineate them and careful description tells us how to use them. The author is far from condemning the uterine sound. Except in pregnancy and cellulitis it is incapable of doing harm if properly used. The routine rectal examination he thinks unnecessary, but urges it in virgins, as a preliminary to vaginal examination, often obviating the necessity for the latter. "General Consideration of Gynecological Surgery," by E. C. Dudley, A.B., M.D. In this article general antisepsis, the use of opium, quinine, and ice, are studied; the important question of "when to operate" is discussed, with "preparatory treatment;" in short, all the practical minutiae of operative procedure are carefully enumerated. "General Therapeutics," by Alexander H. Skene, M.D., is another valuable contribution, which aims to give the reader "a rational system of therapeutics." The study of different remedies and their value in this chapter is excellent.

"Electricity in Gynecology," by G. D. Rockwell, A.M., M.D., and "Menstruation and its Disorders," by W. Gill Wylie, M.D., form the next two chapters, followed by one on "Sterility" by A. Reeves Jackson, A.M., M.D. "Diseases of the Vulva," by Dr. Matthew D. Mann, treats of malformations, injuries and wounds, hernia, vulvitis, ulcerations, œdema, phlebectasia, and hæmatoma, of the skin-diseases affecting the vulva, of vaginismus and coccydinia, and contains, besides wood-cut illustrations, one very fine colored plate of lupus hypertrophicus. Throughout the article the treatment of disease occupies a prominent place, and adds greatly to its value.

Dr. Chauncey D. Palmer contributes the article on "Inflammatory Affections of the Uterus;" also well illustrated, and containing two excellent colored plates exhibiting erosions of cervo-granular degeneration, elongation, catarrh, laceration, chronic hyperæmia, metritis, and endometritis.

"Sub-Involution of the Uterus and Vagina" is by Thaddeus A. Reamy, A.M., M.D., and "Peri-Uterine Inflammation" by Richard B. Maury, M.D. The latter is of especial interest at present, and gains added value from its discussion of the benefits of the antiseptic midwifery. The volume concludes with "Pelvic Hæmatocele and Hæmatoma," by Ely Van De Warker, M.D. These varied and valuable articles cover seven hundred and sixty-nine pages, and in almost, if not

all, cases exhibit a thorough, systematic, and complete study of these various subjects in the light of the knowledge of to-day. We think this work as far as published bids fair to stand first in works of the kind, and contains all that is to be found in many books and scattered in many periodicals here brought together in one accessible and not too voluminous whole. E. W. W.

TRANSACTIONS OF THE MICHIGAN STATE MEDICAL SOCIETY. Vol. IX. 1887.

Detroit: D. O. Haynes & Co.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF MISSOURI. Thirteenth Annual Session. 1887.

St. Louis: W. E. Corveas.

The Transactions of the Michigan Society present us with a number of papers of considerable interest. "How Typhoids are Generated in Germany" is an able article on sewage irrigation. "Some of the Cold-Weather Communicable Diseases" discusses the communicability of diphtheria, smallpox, scarlet fever. Evidently the society, in its discussion of the paper, felt no hesitation in struggling with the great bacteria problem. "The Nature and Treatment of Cholera Infantum" deals with the question of a special ptomaine as the active agent in the production of the symptoms of the disease. Chemically isolated by the writer, Dr. Victor C. Vaughan, he is prepared to prove that it exists in cheese, ice-cream, and milk under certain conditions, and "may be made artificially by the action of nitrous acid gas at a low temperature upon the nitrate-butyrate or other salt of anilin." It is "decomposed when heated with water to near the boiling-point, and is developed in milk by the growth of a germ which multiplies very rapidly when the conditions are favorable." The conditions—limited air and a warm temperature—are found when newly-drawn warm milk is placed in tightly-closed cans and then kept warm. This discovery of Dr. Vaughan has attracted much attention during the past year, and, while perhaps too much stress has been laid upon its importance, it is well to bear it perpetually in mind, though as yet none of the methods proposed for its utilization, none of the agents advanced as antidotes for tyrotoxicon, seem effectual remedies. Time alone will tell whether in this discovery we have the clue both to the causation of certain diarrhœas and at the same time to an accurate method of cure. The whole article, however, deserves a thorough study, not omitting from

attention Dr. Vaughan's method of preventing by proper care the formation in milk and milk-compounds of this obnoxious substance. Perhaps the most suggestive clinical observation made by the author is upon the recurrence of diarrhoea when even good milk is again reverted to as a food after milk containing tyrotoxin has already set up its diarrhoea. This observation, many times repeated, seems to show that there is still left, after the violent vomiting and purging, something—organisms of the nature of bacteria or ferments—which finds in the pure milk, when given as food, a field for the development of more poison. This is analogous to what occurs after apparent recovery from Asiatic cholera, where a number of observers have attributed serious and even fatal relapses to a few teaspoonfuls of milk. The author of the paper promises to give to the world the results of his further experiments, undertaken "with the object of ascertaining the effects of certain germicides on the development of the poison."

The volume contains many papers of interest: a very good one on "Constipation;" one on "Bergeon's Method;" on "Imperative Impulses in Mental Disease;" on "The Analogy between Acute Idiopathic Pleuritis and Acute Articular Rheumatism," in which the writer endeavors to prove the essentially identical causation of both diseases; very good articles on "Pseudo-Membranous Sore Throat" and "A Few Thoughts on the Nature of Diphtheria."

In the department of "Surgery" we find "Antiseptic Surgery for the Country Physician," an article on "Intubation and Tracheotomy," on "Treatment of Hemorrhoids and Fissure of Anus by Gradual Dilatation," on "Nasal Obstructions." Under "Ovariectomy" articles on "Ophthalmia Neonatorum," "Vaginismus," "Is Gynecology Fashionable?" "On the Radical Cure of Retrodisplacements of Uterus and Procidentia by Surgical Operation," a case of hysterectomy, and other papers. These are all good, live papers, and show a somewhat high average of excellence.

The Transactions of the State Society of Missouri are more brief, but have excellent articles on a variety of topics, among others, "On the Practical Applicability of the Theories of Bacteriology," "Proper Food for Infancy and Childhood, etc.," "Milk as a Source or Medium of Infection;" in fact, a very considerable amount of good, substantial medical work is shown in these papers, proving that the West is fully capable of doing its share in the march of progress. E. W. W.

ANATOMY, DESCRIPTIVE AND SURGICAL. By Henry Gray, F.R.S. Edited by T. Pickering Pick. A new American from the eleventh English edition. Thoroughly revised and re-edited, with additions, by William W. Keen, M.D. To which is added Landmarks, Medical and Surgical. By Luther Hoiden, F.R.C.S.

Philadelphia: H. C. Lea's Son & Co.

How many thousand copies of Gray's "Anatomy" have been sold to the rising generation of doctors in the United States during this last twenty years no one who has not access to the books of the Lea Brothers can well tell. But certainly this work has been a mine of wealth, which has been both carefully and successfully worked by the American publishers. It would be very interesting to know how much of the stream of gold has dribbled into the pockets of the authors and editors of the book. The present volume maintains all the features which have given so great popularity to the work of Dr. Gray. It has been brought up well abreast to the times by the English editor, and has added to it very much of interest during its passage through the Philadelphia press. In most of the figures the arteries are colored red, the veins blue, and the nerves yellow; also in the figures of the bones attachments of the various muscles are outlined red. This certainly gives not only greater picturesqueness but greater distinctness to the drawings, and adds very much to the ease with which they are rapidly comprehended on inspection. Altogether the book, as it now stands, is probably the most useful for immediate hurried reference, as well as for the purposes of the student, that there is in the language. Of course it lacks the completeness and minuteness of such a great work as Allen's "Anatomy," or even the two-volume book of Sharpey and Quain.

INSANITY: ITS CLASSIFICATION, DIAGNOSIS, AND TREATMENT. A MANUAL FOR STUDENTS AND PRACTITIONERS OF MEDICINE. By E. C. Spitzka, M.D.

New York: E. B. Treat, 1887.

We confess to a feeling of disappointment when we found that this work of Dr. Spitzka, of whose approach to our editorial table we had previously heard, was nothing but the second edition of his well-known manual, and not the larger treatise which the preface of the first edition made us hope soon to see. It is hardly necessary to notice in detail the second edition of a book which follows so soon upon the first. It is sufficient to reiterate the opinion, that we affirmed after

careful reading of the first edition,—namely, that the work is, upon the whole, the most satisfactory study of insanity that we know of in the language. It is a great pity that Dr. Spitzka could not find a publisher who would make his volume more attractive in the matter of type and paper. Possibly fifteen cents a volume are saved in the cost of publishing the book, but we opine most readers would sooner give three dollars for a handsome book than two dollars and seventy-five cents for the one that is before us.

Correspondence.

LONDON.

(From our Special Correspondent.)

I am writing to you in the beginning of November, but the shades of the waning year are already falling upon us. We have passed through the first outburst of acute catarrhs and congestions begotten by cold and damp, or by the organisms, as some of our friends would say, which arise and flourish in the inclement and unpropitious meteorological conditions that characterize the opening of an English winter. Christmas will presently be here, with the pleasant respite from labor, and the few days of air and sunshine with our friends in the country, which, it is to be hoped, some of us may manage to secure. Meanwhile, we are hard at work. The winter session at the medical schools is in full swing. The societies leave us hardly one quiet evening at home out of the six. The journals are supposed to be publishing more attractive and useful communications than those which satisfied the editorial conscience and their limited circle of readers in the silly season. With all this the question rises in the thoughtful mind, What progress can be claimed during the year that is dying? As one grows older and more gray one comes to be more accustomed to slowness in real advance, to be satisfied rather with steady, even if it be but small, improvement, than to be prospecting and retrospecting for startling epoch-making discoveries.

Therefore it is that I am not dissatisfied with our record for the passing year. From my present stand-point I can see that we are nearer the truth in certain great questions pathological, and have attained to greater success in certain great matters therapeutical, than was our position in November, 1886.

Beyond all question the greatest develop-

ment in treatment with us during the year is to be found in *surgery*. I do not mean by this to directly insist upon the successes achieved by English surgeons in their formidable undertakings on the brain and abdominal cavity, brilliant though these undertakings are. I do not refer to operations, but to *operating*. There is something about the whole proceeding in the excision of a breast or the removal of a kidney nowadays that strikes us as perfectly unlike the method of operating a few years ago. At the bottom of this change for the better lies one great principle,—cleanliness. Whether we choose to regard this as a pathological or as a therapeutical advance matters nothing: when the science of medicine is perfect, pathology and treatment will stand side by side in their mutual interdependence. Perchloride of mercury has undoubtedly attained a high position as a disinfectant and antiseptic during the past twelve months, while iodoform holds its own in its proper sphere of application. With these and other antiseptics, and with the clear appreciation of the principles on which they act, the surgeon now finds the field of his operations increased to an almost unlimited extent.

A continued effort has been made in England, during the year, as well as on the Continent and with yourselves, to *press* into the service of the physician those disinfectant measures which have gained so much credit for the surgeon. But, unless where the knife can reach, I fear but little real improvement has been effected in this way. We can now treat empyema with something approaching satisfaction, but phthisis remains an *opprobrium redendi*. Intrapulmonary injections have been tried without success,—to put the result as favorably as possible. Inhalations continue to hold a place in the practice of many, but are as consistently deprecated by authorities of equal eminence. The year has practically seen the birth and the death of the Bergeon treatment in this country. I have failed to find a single word spoken in favor of intrarectal injections in England, always excepting the occasional record of a successful case, valueless, of course, from a scientific point of view. Not that the method has been condemned untried. Although we have not arrived at the pitch of enthusiasm on this subject which you appear to have reached in the States,—to judge by the number of advertisements of apparatus in the sheets of your medical journals,—still, I am assured that the gaseous enemata have been

fairly tested. With this experience fresh in our minds, let us be more cautious and critical in the future.

When we turn to the department of diseases of the *heart*, we are tempted to point at once with a sense of satisfaction and insular pride to the secure position which strophanthus continues to hold among the cardiac tonics. Of the value of this drug there can be no doubt. Much has been written, in a loose and casual way, about the use of strophanthus in dropsy; and many comparisons, for and against it, have been drawn with digitalis. All this is little to the point; but the fact remains clear and unquestionable that Professor Fraser, of Edinburgh, has introduced to us a cardio-vascular agent of the first rank, which rapidly increases the cardiac force and raises the arterial pressure in cases of dilatation of the heart, and which evidences its power for good both by free diuresis and by speedy amelioration of subjective distress. With the advance of strophanthus in estimation may be said to have occurred the comparative decline of convallaria and caffeine, about which we heard so much a few years ago. Neither of these drugs appears to possess the reliability of digitalis and strophanthus. It is only our leading authorities that seriously attempt to discriminate the cases of heart-disease suitable for each of these drugs respectively, or for combinations of any two of them. I gather that in England there is a pretty general agreement with the view that has been lately arrived at on the Continent from experimental evidence, that caffeine is strictly a direct renal stimulant, not a cardiac tonic; and that to secure its full action in dropsy we ought to combine it with digitalis, convallaria, or strophanthus.

Our specialists in diseases of the *nervous* system are not as a body known for their confidence in therapeutics: their attention is so fully occupied with the investigation of the pathological and regional diagnosis of cerebral and spinal disease that they have but little time or enthusiasm left for other than routine treatment. Yet the soundness of the method that they pursue—the thorough investigation of the nature of disease as the first step—has lately been proved by brilliant therapeutic results. Foremost in this connection comes, of course, the surgical treatment of tumors of the brain and cord, some instances of which I have had occasion to mention in my recent letters to you. Next in importance to these results must be regarded, in my opinion, the discovery and treatment of peripheral paralysis,

especially alcoholic paralysis. This disease proves to be far more common in England than we had any idea of; and it is not easy to exaggerate the amount of benefit that has been accomplished for patients since it came to be generally recognized and properly treated. No clearer illustration than alcoholic paralysis could be adduced at this moment of the soundness of the view expressed in an early part of this letter, that the best kind of progress in medicine is that which is slow, steady, and unphenomenal.

We have heard very little, so far, in England of the application of the newer methods of investigating and treating diseases of *digestion*. You know what I refer to,—the method of systematically emptying the stomach by various means, whether after a test-meal or not, and whether for the purpose of diagnosis or of treatment. Abundant attention has lately been drawn to the use of the stomach-tube in articles in our journals bearing on the observations of German and Russian physicians, and only a couple of weeks ago Dr. Clifford Allbutt brought the subject forcibly before the Medical Society of London. I fear our patients have too much of a dislike—not to say horror—of forcible evacuation of the stomach for this method ever to be much practised here, unless in urgent cases of dilatation, when relief by siphoning is eagerly practised by the sufferers themselves after a little education. We must be content to accept the conclusions arrived at by our continental *confrères* when they are a little more settled than is the case at present, and then, I trust, we shall be able to make a considerable advance on the present system of treating indigestion.

In the department of diseases of the *skin* we have again to acknowledge that we are content to adopt improvements that have recently been introduced to our notice from Germany. The paper which Dr. Unna, of Hamburg, read in Dublin, in August, on the treatment of cutaneous affections by glycerin, gelatins, salve-mulls, and plaster-mulls, appears to me not only to be a contribution of the greatest practical value, but to deal with the therapeutics of diseases of the skin in a far more scientific fashion than had ever previously been attempted.

Among the *newer drugs* that we are now using are jumbul-seeds and saccharin. Both of these may be of use in some cases of diabetes to make life more tolerable, if not to cure the disease. Saccharin is already being extensively employed both by the profession

and by the laity, and will, let us hope, diminish the amount of "liver" in this country. So far I have heard nothing in England of your wonderful new remedy stenocarpine, or gleditschine, or whatever it is to be called, but it is certain to be tested at the earliest opportunity by some of our very active ophthalmologists.

I feel that I cannot fittingly conclude this brief and imperfect summary of the principal advances of therapeutical science in England during 1887 without recording an attempt that is now being made to organize our work in this subject. I refer to the establishment of a therapeutical society in London. I cannot tell you much that is definite about this proposal; but it is at least encouraging to know that thought is being stirred among us in the interest of scientific treatment. So far, I believe, the organization is mainly or entirely on paper; but if it be the case that Professor Ringer has accepted the presidency of the society, and as the movement appears to be in the hands of a very active council, a good beginning ought to be secured for it. No doubt there will be plenty of advice forthcoming as to the ends and methods of a learned body of this kind. Possibly it may follow the lines of the better part of Dr. Whitla's Dublin scheme, which I criticised freely in my last letter to you. The field lies open to our hospital physicians; the material is practically unlimited; the results are highly promising. Let us hope that by this time next year it may be in the power of your London correspondent to render you a better account of service done in that department of our profession which the *GAZETTE* so worthily represents, and the promotion of which ought to be and ever must be the chief end and glory of scientific medicine.

PARIS.

(From our Special Correspondent.)

When Dr. Luys read before the Academy of Medicine his extraordinary memoir on "Therapeutics from a Distance" (*"Thérapeutique à Distance"*), it will probably be remembered that a committee was appointed to examine the facts critically. But academical committees are proverbially slow, and medical societies have begun inquiries of their own, without waiting for the decision of the old lady in the Rue des Saints-Pères. At a meeting of the Therapeutical Society, Dr. Constantin Paul related the following experience.

He supplied Dr. Bourru, of Rochefort, with a very sensitive subject, and requested him to repeat the experiments in question. The conditions were the best possible; but few persons were present, and full latitude was left to the performer. If Dr. Bourru was unsuccessful, he must blame no one but himself. The first experiment was with a vial of alcohol; but, as the container was, contrary to all rules, left uncorked, and the sense of smell is very acute in hypnotized subjects, the whole trial is questionable. Dr. Bourru pointed out the titubating gait of the patient when just awakened; but the same symptoms being observed when subjects recover from the hypnotic state, the experiment remains doubtful. In the next trial, the vial was applied to the right side of the occiput. The patient manifested a feeling of comfort and satisfaction that should have been caused by the cherry-laurel water supposed to be in the vial. Unfortunately, owing to some misunderstanding, the pharmacist had filled the bottle with plain water! Five or six other experiments were quite as doubtful, and prove absolutely nothing. No reason exists, therefore,—and it should be widely made known,—for the public excitement consequent upon Dr. Luys's communication. Dr. Voisin, having, on his side, instituted another series of experiments with different subjects, reached the same conclusion,—namely, that Drs. Luys, Bourru, and Burot are mistaken. Before the Medico-Psychologic Society he declared it his opinion that the phenomena attributed to the so-called "therapeutics from a distance" are the outcome of suggestion and the retentive memory of hypnotized subjects. The facts related were as follows: The patient, a female, having been brought into hypnotic sleep, and perfect silence being observed by the bystanders, a number of sealed vials were placed in contact with the subject, who had been left in ignorance of the intended experiments. No change of any sort was observed. Then Dr. Voisin, holding an empty vial, drew near her, saying he was going to try on the patient the effects of medicaments from a distance, and would successively bring by her several medicines, which would diversely affect her, according to their nature. "Here is alcohol," he said, "which will rapidly cause inebriety, the effect disappearing as the vial is removed." Having brought the empty vial close to the patient, symptoms of inebriety were manifested, which disappeared when the bottle was removed. Next, simulating the motion of

taking other vials, but always bringing the same empty bottle close to the subject, he announced the different effects to be expected from strychnine, cherry-laurel water, valerian, pilocarpine, etc. The phenomena predicted never failed to appear. Two months later Dr. Voisin put the same subject again into the hypnotic state, and made, as before, the announcement that the patient would be able to distinguish the medicaments by the symptoms she would exhibit. Then, repeating the same performance as before, but not naming the supposed medicine, he brought the empty bottle close to the patient. Strange to say, with every pretended change of vial the subject manifested the same symptoms as in the previous experiment, and precisely in the same order, without a single mistake, thus illustrating the extraordinary memory of hypnotized patients. The only conclusion to be drawn from the foregoing is that *thérapeutique à distance* is a delusion, and that the phenomena observed belong to the domain of psychology, not therapeutics.

Such is not the case, however, with *complaints against antipyrin*,—a topic decidedly therapeutical. Poor antipyrin! evil days seem to have fallen upon it. Barely six months ago praises only could be heard from all sides, and now complaints and condemnation come pouring in from all quarters. The pharmacists were the first to find fault, and with good reason. The article supplied for some time past by the German patentees has been most impure and unfit to use medicinally, owing to its offensive smell of benzole. As an excuse, the manufacturers claimed it was necessary to crystallize antipyrin from a benzoic solution, and that the demand has been so large and unexpected that it had not been possible to sufficiently free the crystals from the solvent. The Paris Pharmaceutical Society made short work of such pretexts by showing that antipyrin can very well be crystallized from ether, or even distilled water, and that pharmacists had been obliged to thus purify themselves the bad chemical supplied by the monopolists; so that there was no excuse, if there ever be, for issuing an impure, foul-smelling medicine. It is even said legal steps are to be taken to set aside the French patent as null and void. With this side of the question we have nothing to do; but what is of more concern—even than defective fabrication, probably temporary—is the number of complaints made by physicians against the effects of antipyrin. Dr. Finot, of the Medico-Practical Society, was the

other day relating how a patient, treated last October with two hypodermic injections of antipyrin, suffered two days later from cellular induration and erysipelas to such an extent as to be obliged to keep stooping forward from pain and inflammation. Proper antiphlogistic treatment, during ten or twelve days, avoided the formation of the threatened phlegmons, but two painful indurated centres are still existing, while their resolution remains yet doubtful. Dr. F. Roux made a report equally unfavorable. "I gave antipyrin," he said, "in the doses recommended to three patients suffering from migraine. One experienced profuse perspiration, nausea, and vomitings. The pain was in no way relieved, and, when the fit had run its natural course, the patient felt weaker than ever before. The second was not hurt by antipyrin, but neither was he relieved in the least. And, finally, the third patient experienced some marked relief, but not the instant cure spoken of by Dr. Germain Sée. In a patient suffering from rebellious sciatica antipyrin exhibited both through the stomach and hypodermically produced no result. The injections were very painful, but the aching remained. And, lastly, a hysterical patient, affected with abdominal neuralgia, took antipyrin without the slightest benefit. I should like to know whether my brother physicians have observed similar results."

The therapeutic action of *bismuth salicylate* offers some peculiarities that it may be well to bear in mind. Dr. Legendre, the other day, was relating before a medical society some facts which had somewhat puzzled him. In Dr. Grancher's service it seems salicylate of bismuth is frequently employed in gastrointestinal affections and typhoid fever. For some time past it has been noticed that children subjected to this treatment often passed salicylic acid in their urines, and occasionally experienced the well-known cerebral disturbances characteristic of salicylic acid. Having inquired of the hospital pharmacist, he was only informed that the salt of the market is apt to be, at times, a mere mixture of salicylic acid and subnitrate of bismuth. Dr. Legendre thought the statement might be true, yet the explanation hardly satisfied him, and he called upon some of the members present for some better solution, when Dr. Bouchard remarked that there are two compounds of bismuth and salicylic acid, one basic and the other acid, and both easily give up their acid, especially the non-basic salt. Salicylate of bismuth, as such, is not an anti-

septic, but becomes one whenever fermentations take place, which set the acid free. When salicylate of bismuth is administered alone, as various fermentations and putrefactions occur in the intestines at the time it reaches there, acids are generated,—the hydrosulphuric among them,—which displace the salicylic acid from its combination. The latter will now appear in the urine, while the fæcal matters will be colored black by sulphide of bismuth. But if salicylate of bismuth be associated with other antiseptic substances, most likely such black coloration will not be observed, and no salicylic acid will appear in the urine. Whenever such symptoms are noticed, they can be made to disappear through the administration of antiseptics, because on effecting intestinal antiseptics the decomposition no longer takes place.

Melinite, as an explosive, is, of course, chiefly of concern to surgeons, but as a poisonous compound it belongs to therapeutics, while its novelty provokes the curiosity of all. Dr. Tachard, an army surgeon-major of the first class, has given an instructive account of the effects of the new French explosive. An accident occurred, not long since, in a fortress while men were preparing melinite bombshells. Out of the seventeen soldiers within range eleven were killed on the spot, or died shortly afterwards. The survivors' wounds deserve the following remarks: To begin with, no burns could be noticed, and no accidents that could be attributed to the inhaling of poisonous fumes. Hence melinite acts only mechanically. From a surgical point of view, a fact deserving notice is the great number, depth, and small size of the wounds, dangerous in character, caused by very minute fragments of cast iron, barely larger than a grain of sand. The particles extracted were of irregular shape, with sharp edges, but free from smell or foreign chemical compounds. A remarkable fact is that the effects on the bones were strictly local, and no fissures or slits could be observed, such as are seen with ordinary bullet wounds. The extreme violence of the impact suffices to break the bone at the first point of contact, and it is only further on that the parts become broken, as the cast iron penetrates into the bony structure. The general aspect of the wounded is characteristic. The uncovered parts have an intense light-yellow color, rapidly spreading, so as to stain the linen. Deathly pallor overspreads the face. Some patients are almost prostrated; others, on the contrary, are excited, and groan restlessly.

The small wounds riddling the body, and closed with a clot of blood, were about two millimetres (one-twelfth of an inch) in diameter, ten or fifteen centimetres (four to six inches) deep, and contained a parcel of cast iron the size of a grain of sand. The treatment followed was the usual one indicated from the nature of the wounds, and was reasonably successful. But an idea that suggests itself is to use powerful electro-magnets for the purpose of helping the removal of the foreign metallic particles.

An improved formula for *artificial serum* may prove useful to blood specialists. Dr. Mayet, of Lyons, has recommended the following: Distilled water, 100 grammes; anhydrous phosphate of sodium, 2 grammes; sugar, enough to bring the solution to sp. gr. 1.085. As most microscopists are conversant with the metrical system, it is probably unnecessary to translate the foregoing into Troy weights. Dr. Mayet finds the liquid an excellent medium for preserving blood-corpuscles and globular elements without alteration, so that they may easily be counted and examined in cases of anæmia, leucocythæmia, etc. Owing to the density and slight viscosity due to the sugar, and the preserving action of the alkaline salt, the different elements are prevented from adhering together, and equally distributed in the fluid. Only, the liquid layer between the plates being thicker than with other media, the focus must be adjusted so as to distinguish separately the various elements of different densities floating in the artificial serum.

PARIS, November 18, 1887.

OIL OF SASSAFRAS TO DISGUISE THE ODOR OF IODOFORM.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In your October number I see that "C. E. Dodsley affirms that the addition of four drops of the oil of sassafras to the ounce of iodoform completely does away with the disagreeable odor." You well added, "This is certainly important, if true."

Having had occasion to use a great deal of it in the past few weeks, I tried his suggestion, and find that in the bulk form the oil does disguise the disagreeable odor; but as soon as the iodoform comes in contact with the skin, or with a sore, the oil seems to evaporate, and leaves the odor as pungent as ever. I have given it a thorough trial, and I am sorry to find that the oil does not prevent the

disagreeableness of its application (the smell). I have left the bulk in contact with the open air, and the oil does not evaporate, but, strange to say, it only requires contact with the skin to bring out the full odor. I hope some one else will favor us with his experiments in this line, as I stand open to corrections, and hope it may be proven that I have been mistaken.

Very respectfully,

JOHN H. HARDEN, M.D.

CHERAW, S. C., November 19, 1887.

Notes and Queries.

PEMPHIGUS, ARSENICAL PIGMENTATION, UNUSUAL AFFECTION OF CICATRIX.

At a recent meeting of the Clinical Society of London, DR. HANDFORD (*Brit. Med. Journ.*, October 22, 1887) reported a case of pemphigus occurring in a child aged 13, and terminating in incomplete recovery after nearly a year. The limbs, trunk (except parts of the chest and abdomen), face, tongue, mouth, pharynx, mucous membrane of the nose, conjunctivæ, and orifice of the vagina were all affected. The eruption came out in crops, and was accompanied by rise of temperature. Micro-organisms were found in the bullæ which contained pus, but not in those which contained serum. Quinine in large doses was given with benefit, and arsenic. Of the latter, 15-minim doses of Fowler's solution were given thrice daily, and continued for ten weeks. After this the skin of the whole body was noticed to be dry, brawny, and darkened in color. The axillæ, groins, and abdomen were almost as dark as in Addison's disease. The skin looked dirty, but the color was proved to be due to pigment, deposited chiefly in the rete, but partly in the more superficial epithelium. The arsenic was stopped, and the patient treated by wet-packing, and in a month the skin had resumed its normal, smooth, moist appearance, and much of the pigmentation had disappeared. Also on the hands and feet there were many elongated patches of cicatricial-looking skin, thickened and elevated. These patches were covered with white points, like millet-seeds, just beneath the epithelium, and resembling, to the naked eye, miliary tubercles. They were not tubercular, but consisted of accumulations of degenerating epithelial cells in the deeper part of the epidermis. They disappeared in four or five months. It was possible that this

condition also was due to the arsenic. Several colored drawings and photographs illustrating these conditions were exhibited. A third case of pemphigus was described, in which there was some ground for suspecting implication of the mucous membrane of the intestinal canal. It presented also the atrophied glossy condition of the skin of the hands mentioned in the first case, and which was suggestive of an implication of the peripheral nerves. No definite affection of sensation or of the reflexes, however, could be discovered, though reference was made to the statement of Dr. Pasquale Ferraro, that he had found advanced changes of an atrophic degenerative nature in the posterior horns of the dorsal spinal cord, and also in the peripheral nerves, the ganglia on the posterior nerve-roots, and in the sympathetic ganglia. Two further instances of arsenical pigmentation were narrated, and the opinion was expressed that small doses of arsenic (m̄ v to m̄ x) of the liq. arsenicalis repeated thrice daily for about two months were capable of producing a pigmentation of the skin, chiefly of the abdomen, lower part of the chest, lumbar region of the back, axillæ, groins, and inner parts of the thighs. This condition was not necessarily accompanied by roughness and dryness of the skin, and disappeared slowly in from one to four months, or rather longer.

DR. CROCKER, referring to the pigmentation of the skin, said that this was fairly common on the site of eruption, as a result of the treatment of psoriasis by arsenic. General pigmentation, however, was less common, but did, nevertheless, occur from time to time. He had then under his care a boy with a bullous erythema, which he was treating by arsenic. Latterly the boy's skin had become pigmented. He thought it should be generally known that pigmentation was likely to follow prolonged treatment with arsenic, quite independently of the eruption. It was probably due to a deposit of the metal itself in the skin. The pigmentation lasted a very considerable time, much longer than four months, as mentioned by the reader of the paper.

DR. GOODHART took up the question of fever mentioned by the reader of the paper, he having a case now under his notice, in a little girl, in which high fever occasionally occurred. He said that this case showed very plainly the peculiar property of arsenic to control the disease, though not to cure it. In this case the dose of arsenic required to subdue the eruption was so high that it could

not be continued, and then the eruption recurred.

SIR DYCE DUCKWORTH wished to add his testimony as to the value of arsenic in the treatment of pemphigus. He had formerly been sceptical as to the benefits claimed for its use, but had more recently had ample proof of its efficacy, several cases having been apparently quite cured thereby. In one of these cases marked pigmentation had followed the use of 12 minims of arsenical solution three times a day.

FLUID EXTRACT OF PICHU IN VESICAL CATARRH.

DR. H. S. DELAMERE, of Lubec, Me., referring to the use of pichu in the treatment of catarrh of the bladder, as reported by Dr. G. T. Comstock, relates the following case in the *Medical Record* for November 12, 1887:

"A. B., aged 28, had been suffering for two years from vesical catarrh. He had had gonorrhœa, but a No. 21 (French) bougie passed without difficulty, causing, however, considerable vesical tenesmus. When I was called to see him he was passing urine every hour during the day and four or five times during the night. The urine was alkaline, ropy, ammoniacal, and the microscope revealed pus. I gave the usual remedies prescribed in country practice, such as buchu, uva ursi, etc., but without benefit. I then resorted to washing out the bladder by means of the double-channel catheter, with the effect of relieving my patient slightly. The least exposure, however, aggravated all the symptoms and caused as much suffering as ever. After about a year and a half of constant treatment, with no other result than to keep the disease at bay, I received a sample bottle of fluid extract of pichu, which I tried. After the patient had taken it a few days he expressed himself as feeling better. He was now getting up twice during the night. But the sample was gone, and I was obliged to wait until I could get a fresh supply. In the mean time the patient grew worse; had to get up three or four times during the night. As soon as the drug arrived I commenced giving him 20 drops four times a day, which dose I increased to 30 drops. In a few weeks my patient was so much better that I abandoned washing out the bladder, and to-day he is at work. The urine is clear, free from mucus and pus, and has no ammoniacal odor. He sleeps well, and does not have to get up more than once during the night. Notwithstanding

he has suffered recently from a severe cold, the bladder-trouble has not returned. The man's general appearance is healthy, appetite good, and he seems well."

THE ACIDS OF THE STOMACH IN HEALTH AND DISEASE.

The following are the results of a series of researches made by Drs. CAHN and VON MERING concerning the acids of the stomach in health and in disease (*London Med. Record*, October 15, 1887): 1. The quantity of lactic and hydrochloric acids in the stomach can be determined. 2. In the healthy subject hydrochloric acid is found in the stomach half an hour after eating. 3. Under an exclusive meat diet hydrochloric acid alone is found. 4. In a mixed diet the stomach contains, both in a healthy and diseased state, hydrochloric, lactic, and volatile acids, the quantities varying according to the length of time the food remains in the stomach. 5. In fever and anæmia hydrochloric acid may be wanting, but it is always present in amyloid cachexia, and it is only exceptionally absent in carcinoma of the pylorus. Violet of methylaniline does not form a reliable test for the presence or absence of hydrochloric acid in the stomach.

THE VALUE OF THE FLUID EXTRACT OF QUEBRACHO.

According to the experiments of Dr. M. BOURDEAUX (*Archives Médicales Belges*, April, 1887) the fluid extract of quebracho is a most energetic promoter of healing.

If painted or applied to wounds with a smooth surface it causes at first a slight passing sensation of pain (similar to that caused by an application of collodium), and promotes healing by first intention. It may be also used in burns and wounds caused by freezing, if the ulcerated spot has a healthy, rosy appearance. The extract, when painted on the wound, hardens in the course of an hour, and forms a hard brown crust, which clings firmly to the tissues, and can only be removed with warm water. The secretions of the wound dry up, and healing rapidly takes place, after which the brown crust will fall off.

The great advantage of this treatment is that it does away with all bandaging.—*Le Progrès Méd.*, October 5, 1887.

*THE TREATMENT OF CHOREA AND
OTHER HYPERKINETIC DISEASES
WITH PHYSOSTIGMINE.*

DR. L. RIESS treated forty cases of chorea with physostigmine in subcutaneous injections of .001 ($\frac{1}{84}$ grain) once or twice a day, and found that its use resulted in materially shortening the length of the disease. He also observed a beneficial action of the drug in twelve cases of tremor (senile, alcoholic, and hysteric, etc.), and in four cases of paralysis agitans, in two cases of multiple sclerosis, and in three cases of Charcot's post-hemiplegic chorea. It was tried in five cases of tetanus, but the drug did not have as good an effect as might have been looked for, as it did not lessen the irritability of the central nervous system to any great extent.—*Zeitschrift für Therapie*, October 1, 1887.

*BROM-ETHYL AND ITS VALUE IN
DENTAL OPERATIONS.*

After a dissertation on the different anæsthetics used in surgery, both dental and general, such as ether, chloroform, laughing-gas, etc., DR. JULIAN SCHEPS, of Breslau, launches into an elaborate account of brom-ethyl, and of its great usefulness as a narcotic in dental surgery. He contends that it in a measure combines the valuable properties of both chloroform and laughing-gas. It resembles the former in its easy and simple method of administration, and the latter in the shortness of the effects and the rapid recovery from them. It is, however, neither accompanied by the danger of the first, nor does it necessitate the bulky and complicated method of administration of the second.

Brom-ethyl, ethylum bromatum, or ether bromatus (C_2H_5Br), is a colorless fluid, smelling like ether, of neutral reaction, neither inflammable nor explosive, and evaporating with great rapidity when exposed to the air.

In the year 1849 it was recommended by Nunnely as a general anæsthetic, but was not thoroughly investigated or studied until the years 1876 and 1877, by Rabuteau, who found, when experimenting with the drug on animals, that it was a quicker anæsthetic than chloroform; it had not, however, the irritating properties of chloroform. Brom-ethyl is entirely eliminated by the lungs; no trace of the drug was found in the urine. If the drug is inhaled for more than a half-hour, the animal will gradually die, the death being caused by gradual cessation of circulation and stoppage

of the heart's action. Rabuteau's personal experiences with the drug were as follows: At first he experienced a slight ringing sensation in the ears, and after two minutes of deep breathing there was a lessening of the pulse-frequency and a wonderful decrease of the amount of breath required.

Since 1877 brom-ethyl has been used with great success in operations of the eye and ear by Dr. Turnbull, of Philadelphia, and later Dr. Levis, of the same city, used it in larger operations.

Terillon considers it to be a good local anæsthetic; he used it in spray form, and considered it much better than ether.

Dr. Levis lays particular weight on the remarkable rapidity with which it causes anæsthesia, as it acts in one-third the time that chloroform does, and also calls attention to the quick recovery from its effects and the almost entire absence of nausea and vomiting, and further states that its influence on the circulatory system is but slight.

All practitioners do not, however, by any means agree with Dr. Levis, or join him in praising the drug, as here and there serious results have followed its use. Two cases of death were reported by Dr. Roberts and Dr. Marion Sims as having resulted from its use.

Dr. H. C. Wood says that brom-ethyl has a directly paralyzing effect on the muscles of the heart, and thereby causes a marked decrease of the pressure of blood, and therefore is equally as dangerous as chloroform. Dr. Scheps states, however, that the dangerous symptoms only occur after long-continued inhalation, and he holds that the drug is perfectly safe in short operations.

The drug, says the author, should be administered in the same manner as chloroform, on an Esmarch's mask.

Terillon advises its being poured on a compress which covers the face, but Dr. Scheps says the mask only should be used under all circumstances.

The patient should be placed as horizontally as possible.

The author then gives a minute description of several remarkable cases, and gives a large number of other cases in tabular form.

All the cases relate to the extraction of diseased teeth.

The average dose of brom-ethyl required to produce anæsthesia was 15 grammes (4 drachms).

In most cases the patient was conscious of the extraction, but experienced no pain whatever. The author is of the opinion that in

introducing brom-ethyl into dental surgery he has brought forward an anæsthetic which can be rivalled by none.

Whether this is the case or not is very doubtful, and cannot yet be fully determined, as the drug has been but slightly tested and has but a limited use. It will be difficult, however, to find an anæsthetic which will take the place of laughing-gas.—*Centralblatt für Chirurgie*, September 24, 1887.

ANTIPYRIN INJECTIONS.

In order to avoid the pain consequent sometimes upon the subcutaneous injection of antipyrin, a comparatively dilute solution is used when possible. But in cases where in order to give immediate relief it becomes necessary to inject a large dose, such as a gramme of antipyrin dissolved in a gramme of water, PROFESSOR SÉE adds 15 to 20 milligrammes of cocaine hydrochlorate to each injection.—*Pharmaceutical Journal and Transactions*, October 29, 1887.

COCAINE CHLOROMERCURATE.

The addition of mercuric chloride to solutions of cocaine hydrochlorate intended for ophthalmic practice has been recommended, and a preparation used on the Continent under the name of "Sattler's solution," containing five grammes of cocaine hydrochlorate and two centigrammes of mercuric chloride to one hundred grammes of water, is generally esteemed to have antiseptic as well as anæsthetic properties. In experimenting as to the correctness of this assumption, MESSRS. BALBIANO and TARTUFERI found that when mercuric chloride is added to a solution of cocaine hydrochlorate a double salt is formed, having the composition represented by the formula $C_{17}H_{21}NO_4Cl.HgCl_2$ (*Ann. Chimica e di Farm.*, September, 1887, p. 157). The presence of this compound can be demonstrated by the formation of a white precipitate when the solution is moderately concentrated. The double salt was prepared separately, and was obtained as a white crystalline powder, melting at 122.5° to 123° C., and forming, upon cooling, a hard vitreous mass. It is only slightly soluble in cold water, one hundred cubic centimetres at 21° C. only taking up 0.536 gramme, but it is still less soluble in five per cent. solution of cocaine hydrochlorate, one hundred cubic centimetres at 24° C. only dissolving 0.135 gramme of the chloro-

mercurate. Experiments were then made to test whether this compound confers any antiseptic properties upon solutions of cocaine hydrochlorate in which it occurs, the conclusion drawn being that in the proportion chloromercurate of cocaine is present in Sattler's solution (0.0425 per cent.) its influence as an antiseptic is negative.—*Pharmaceutical Journal and Transactions*, October 29, 1887.

LAMINUM ALBUM.

Laminum album is a labiate indigenous to Central Europe.

The blossoms appear in commerce under the name of *Flores lamii albæ seu urticæ mortuæ* (the German *Taubennessel*, *Todtennessel*, or *Bienensaug*). When fresh the blossoms have a sweet, pleasant smell, not unlike that of honey, and have a sweetish taste and are slimy. The infusion is largely used among the peasants and country people as a remedy for catarrh.

Recently FLORAIN (*Journ. de Méd. de Paris*, 3, vii., 1887) called attention to the fact that the blossoms of the *Laminum album* were a hæmostatic of the first order. The remedy is said to have been efficacious in cases of bronchial hemorrhage, blood coughing, and uterine hemorrhage where the usual remedies, such as ergotin, acidum tannicum, and the like had been used without success. In metrorrhagia the syrupy extract of the blossoms is used.

The use of the tincture in the following formula is advised :

℞ Tinct. flor. lamii alb., 100 (about ℥iv);
Syrup. sacchari, 50 (℥ii);
Aqua dest., 250 (℥ix).

A half-teaspoonful or a "coffeespoonful" of the mixture should be given every half-hour until the internal bleeding ceases, after which a tablespoonful should be given every four hours until all the symptoms have disappeared.

—*Pharmaceutische Zeitschrift für Russland*, September 22, 1887.

A CASE OF CIRRHOSIS HEPATIS HYPERTROPHICA CURED BY CALOMEL.

DR. SCHNEPP, of Vienna, in the *Wiener Med. Blatt.*, xiv., 1887, speaks of a case of cirrhosis hepatis hypertrophica cured by calomel. The patient was a woman aged 28, who had all the symptoms of cirrhosis hepatis well marked. The liver, upon percussion, was found to be greatly enlarged.

After a course of Karlsbad had been tried for five weeks in vain, and strong purges, followed by free operations, had afforded only slight relief, the author, prompted by the suggestion of Professor Nothnagel, ordered an absolute milk diet, and gave calomel in .05 ($\frac{1}{20}$ grain) doses three to five times daily. On the second day of this treatment the fæces had already assumed a yellow color and the urine had lost the most of its high coloring, and in a few weeks icterus and ascites had disappeared, the liver was much smaller, and menstruation had again set in. In three months the patient had taken one hundred doses of calomel, and complete recovery had resulted. Sensitiveness, enlargement of the liver, ascites, and "caput medusæ" no longer existed.—*Deutsche Medicinal-Zeitung*, September 22, 1887.

ANCHIETEA SALUTRIS.

Anchietea salutaris St. Hil., belongs to the family of Violaceæ, and is found largely in Brazil and Guiana. The root of this climbing vine, which is called sipo or suma by the natives of Brazil, contains a but slightly known alkaloid called anchietine, to which emetic and anticatarrhal properties are accredited.—*Pharm. Zeitsch. für Russland*, September 22, 1887.

VATAIREA GUAJANENSIS.

The seeds of the *Vatairea guajanensis*, powdered and mixed with fat, are used as a salve in herpes serpigio and other skin-diseases. The brown-colored hulls, which contain the flat seed, are round, and of a leathery texture, with a hollow rim or edge, and do not burst open.

According to the *Pharm. Journal* the wood of the *Vatairea guajanensis* has an intensely bitter taste. The inner rind or bark is similarly used as the leaves. The drug is still being carefully studied and experimented with.—*Le Progrès*, Geneva, October 5, 1887.

PARTHENIUM HYSTEROPHORUM.

A new antifebrile remedy in England (*Pharm. Post*, 1887, No. xx., p. 442) is *Parthenium hysterophorum*, a plant which is indigenous to the West Indies and Louisiana. The active principle which it contains is a bitter alkaloid, which, when given internally, causes an in-

creased secretion of the salivary glands, but has no effect on the secretion of urine.

According to DR. TOVAR, of Cuba, *Parthenium hysterophorum* is used there as a household remedy for malaria, and he recommends it himself as a good febrifuge. MR. EGASSE, *Arch. de Pharm.*, 1886, used parthenium as an antineuralgic and febrifuge in doses of 1 to 1.5 ($15\frac{1}{2}$ to 24 grains), and states that smaller doses do not seem to produce any effect whatever. The results of his experience with the drug are good.—*Pharm. Zeitschr. für Russland*, September, 1887.

EMBELIA RIBES, A NEW REMEDY FOR TAPEWORM.

DR. HARRIS, of Simla, calls attention in the *Lancet* to the value of the fruit of the *Embelia ribes* for tapeworm. He states that the drug has for the last five years been used extensively not only by the natives, but also by the Europeans, with great success.

The dose of the pulverized fruit is from 1 to 4 drachms, which should be given in the morning with milk.

The fruit has an aromatic taste, and is about the size of a pepper-seed. According to Dr. Dymock, they have recently been exported in large quantities to Germany, where they are said to be used as the chief ingredient of several patent tapeworm "specifics." The drug is said to heighten the color of the urine.—*Le Progrès*, October 5, 1887.

ARADIRACHATA INDICA.

Aradirachata indica is a large-leaved zara-dach, and an evergreen belonging to the family of Meliaceæ. It is indigenous to India and Syria, and is largely found growing wild in North America.

The bark is introduced into commerce under the name of *cortex margosa*, or cortex aradirachata ("The Pride of India"). It is official in the United States, and is used as an anthelmintic.

The active principle is a bitter body which has not yet been closely studied, and to which Cornish has given the name of "*margosin*."

According to *Il Farmacista Italiano et il Medico Practico*, the decoction of the bark (60 to 750) and the alcoholic tincture (1 to 5) are both highly recommendable.

The decoction should be given by the teaspoonful, in connection with a laxative, to rid the system of ascarides; the tincture should

be given in doses of 2 to 8 grammes (31 grains to 2 drachms), and is a good tonic.—*Pharm. Zeitschr. für Russland*, September 22, 1887.

SALOL AS AN ANTIRHEUMATIC.

Although for some time past the salol question has been almost exhaustively discussed in this and nearly all the leading medical and therapeutical journals, yet it still belongs to the newer remedies, and is still "on trial," and therefore any further light on its uses and value cannot fail but to interest the readers of the GAZETTE.

Recently BIELSCHOWSKI (*Therap. Monatshefte*, 1887, p. 47), of Breslau, has published an article on salol, which he calls by its euphonic German name, "Salicylsaeurephenylæther," in which he says that for some time he has been using salol for acute muscular rheumatism, and that his opinions regarding the value of the drug in this disease are principally based on the result of a long series of experiments carried out in the Allerheiligen Hospital in Breslau. He considers it a specific; that it is equal in value to salicylic acid, and that it is superior to it on account of the fact that its use is unaccompanied by any unpleasant symptoms. Exanthema, perspiration, or digestive troubles were never observed, and only in one case a slight ringing in the ears was noticed. Bielschowski treated twenty-seven cases in all with salol; nineteen of these (among which fourteen were very severe) were promptly and completely cured by its use. In two cases the drug seemed to exert but little influence, whereas the use of 30 (nearly 1 oz.) of natr. salicylic. *per rectum* resulted in complete recovery. All the other cases, although both salol and salicylic acid were used, turned to chronic muscular rheumatism. Eight cases of relapse were observed, but they were all subsequently cured by salol given in small doses.

The drug was always given in capsules; usually 5 (77 grs.) were given *pro die*, inside of five hours; in a few cases 8 (123½ grs.) were given in eight hours. Smaller doses (2 to 3 = 31 grs. to 46½ grs.) were only used in after-treatment.

The smallest quantity of the drug which was sufficient to cause complete disappearance of the disease was 13 (about 3½ drs.), and the largest quantity that was ever given was 44 (about 1½ oz.).

After the use of the drug the urine assumes

a brownish or dark-brown color (carbolurin), which, upon the addition of a few drops of liq. ferri sesqu., changes into a violet shade.

The experiences of Dr. S. ROSENBERG, of Berlin (*Therap. Monatshefte*, 1887, p. 51), are not quite so favorable as those of Dr. Bielschowski. He also observed the prompt effect of daily doses of 6 to 8 (92½ grs. to 123½ grs.) when given in hourly or two-hourly doses of 1 (15½ grs.). Dr. Rosenberg, however, states that "nearly all" the cases suffered a relapse. Frequently, also, complications set in, such as pericarditis, endocarditis, and pleuritis. In one case the remedy completely failed to have any beneficial action, although its use (in 8 doses (123½ grs.) *pro die*) was continued for two weeks. This same case was then treated with natr. salicyl. (5 to 150), and a complete cure resulted in an incredibly short time. Also in regard to the accompanying symptoms, the experiences of Dr. Rosenberg are far from favorable. He states that he found the use of salol to be accompanied by all the unpleasant symptoms observed during the use of salicylic acid,—ringing of the ears, profuse perspiration, nausea, and vomiting, although the three last-named symptoms did not occur nearly so frequently as with salicylic acid. The ringing of the ears was often observed, and in some cases was quite severe. The smallest daily doses which caused disagreeable accompanying symptoms were 4 (62 grs.).

Dr. Rosenberg considers that salol simply acts as "disguised salicylic acid."

A beneficial action of salol was observed in acute cystitis and pyelitis by Dr. L. FLEISCHENFELD, of Berlin (*Therap. Monatshefte*, 1887, p. 52), and also in prostatohypertrophy. In a few cases the use of the drug had to be discontinued on account of its causing increased pressure of urine. Otherwise Dr. Fleischfeld observed no unpleasant symptoms accompanying its use.

THE VALUE OF HYDRASTIS CANADENSIS IN UTERINE HEMORRHAGES.

The value of the fluid extract of hydrastis canadensis in common menorrhagia is still a contested point among many able practitioners.

Dr. J. M. FUCHS (in the *Wiener Medicinische Blätter*, No. 43, October 27, 1887) states that he has found it of great value in such cases, and also used it with success in a case of profuse menstruation which was undoubtedly caused

by a myoma of the uterus, which was as large as the head of a child. The case is one of special interest, as only very recently the use of *hydrastis canadensis* has been recommended in various affections of the uterus.

The patient was a woman, aged 35, who had been a mother four times, and always had an easy time, unaccompanied by any complications, and even since the birth of her last child (which was five years since) menstruation had always been normal and regular. For the last two years, however, menstruation had been irregular, and occurred every three weeks and lasted from ten to twelve days.

Fourteen months ago Dr. Fuchs saw the woman for the first time. She was greatly reduced, highly anæmic; was, however, wholly unconscious of the existence of the tumor, which was easily discovered, by palpation of the abdomen, to be situated on the front wall of the womb. With the exception of the continued hemorrhage, she said that she experienced no inconvenience from it whatever.

The vaginal portion of the uterus was normal. An examination with a sound was not permitted.

The author gave as a palliative ext. fluid. *hydrastis cand.* in doses of 20 drops four times daily. The first menstruation after its use was six days later than usual, and in three months the menstruation had become perfectly normal.

Dr. Fuchs now discontinued the continual use of the drug, and only gave it ten days before the usual period, and continued it until the menstruation had ceased. Up to the present time, which is over a year, the menstruation has continued to be regular.

Whether the tumor has decreased in size or not the author cannot say, as any thorough or intra-uterine examination is not allowed. At any rate, the symptomatic result is most favorable.

It should further be remarked that the drug was not only well endured by the stomach, but that it also had a beneficial effect on the digestion.

A NEW ANÆSTHETIC.

DR. NJUSCHKON, in the *Casop. Cesk. Lékár.*, advocates the use of *kandol* in the place of ether or cocaine.

Kandol is a product formed by the distillation of naphtha, and is a perfectly clear, colorless fluid, extremely volatile, burns easily,

and smells slightly of benzene. It can be mixed with a small quantity of water or alcohol. The preparation of the drug is simple, and it is very cheap. Its actions can be fully relied upon. It is used in the form of a spray as a local anæsthetic, and in one minute will reduce the temperature to -10°C. , and the drug will keep it pretty uniformly at that temperature for some time, while ether reduces the temperature to -17°C.

The skin becomes very hard, and is completely anæsthetized, and there is either no bleeding at all, or else the blood coagulates as soon as it makes its appearance, so that all operations may be performed with great ease and rapidity.—*Le Progrès*, October 5, 1887.

THE VALUE OF SALOL IN THE TREATMENT OF ACUTE MUSCULAR RHEUMATISM, ETC.

A series of most interesting experiments has been recently carried out in the "Leyden" clinics regarding the use of salol in acute muscular rheumatism, lumbago, omalgia, etc. The drug was given in the form of powder, and in daily doses of 6 to 8 grammes ($1\frac{1}{2}$ to 2 drachms). The effect of the drug was truly wonderful, and could not be alone ascribed to the presence of salicylic acid in salol. In no case did the drug produce any disagreeable accompanying symptoms whatever.

Salol was also given in typhus, pneumonia, pyæmia, ulcerous endocarditis, and diphtheria, and proved itself to be a reliable antipyretic, although only of a medium and not of an excessive intensity.

Apirexia was produced without any unpleasant symptoms, and the accompanying perspiration was moderate. Collapse was not observed in a single case. The diarrhoea was not in the least affected by the drug. The only disagreeable accompanying symptoms that were observed were occasional ringing of the ears and a few cases (especially in typhus) of gastric irritation, nausea, vomiting, etc. In one case only was the use of the drug followed by chills.

In one patient symptoms of carbolic-intoxication were observed in three days, twenty-four grammes (about six drachms) of salol having been administered.

In a case of myelitis, accompanied by paralysis of the bladder, the drug gave very good results, although the urine was in the act of decomposing.—PEIPER, in the *Centralblatt für Klinische Medicin*.

	PAGE
Huamantla	400
Humphreys, B. Frank, Antipyretic Pills	746
Hutchinson, Randall, Physiological Action of <i>Cimicifuga Racemosa</i>	731
Hydatis of Liver, Surgical Treatment of	107
Hydrastine	130
and Berberine	764
and Narcotine, Relation between	356
Hydrastis Canadensis not an Oxytocic	50
in Uterine Hemorrhage	187, 863
Use of	255
Hydrochinone, Effect of, on Urine and Urea	326
Hydrofluoric Acid, Treatment of Phthisis by Inhalations of	556
Hydrogen Peroxide	788
Fatal Result from Injections of	68
in Diseases of the Eye	42
Sulphide in Asthma and Chronic Bronchitis	847
Hydrotherapy, Lecture on	793
Hygienic Therapeutics	361, 433, 577
Hyoscine, Action of, on Eye	414
as a Cerebral Sedative	118
How to Prescribe	72
Hydrochlorate, Physiological Action of	405, 482
Effect of	556
Hydrobromate, Mydriatic Properties of	127
in Kidney-Diseases	187
Recovery from Four-fifths of a Grain of	811
Hyoscyamine, Uses of	51
Reactions for	358
Hyperosmic Acid, Injections of	683
Hypnoscine	253
Hypopydiaz, New Operation for	54
Hysterogenic Zones in Hysterical Subjects	215
Ice-Water Enemata	67
Ichthyol in Surgery	623
Impacted Faeces, Convulsions from, in Child	288
Incompatible Prescriptions	213
Index Medicus	394
Catalogue, The	756
Indian Female, Chest Movements of the	297
Hemp and Belladonna in Whooping-Cough	124
in Certain Types of Headache	333
Indigestion, Cutaneous Disorders from	428
Infant Feeding	69
Insect-Bites, Useful Applications for	620
Insomnia, Cause and Treatment of Functional	615
on a Certain Kind of	811
Intense Cold, Treatment of Neuralgia by	609
Intermittence in Disease	806
International Medical Congress, Programme of	574
Intestinal Injections of Gas, Treatment by	47
Antiseptic, An	71
Irrigation in Catarrhal Icterus in Children	113
Surgery and Intestinal Obstruction	627
Intraperitoneal Injuries, Treatment of	401
Intra-Pulmonary Injections	193
Intra-Uterine Medication, Fatal Result of	358
Intussusception, Treatment of	56
Iodine Irritation	57
Inconveniences in Use of Tincture of	128
Injections of, in Syphilis	121
New Method of employing, for Antiseptic Purposes	839
Iodoform and Calomel	431
as an Antiseptic and Antiparasitic	767
Inunction in Meningitis	488
Oil of Sassafras to disguise the Odor of	857
Powerful Deodorizer for	768
Question, The	461
Iodoformized Ether Injections in Cystitis	622
Iodol in Surgery	640
Notes on	656
Poisoning, A Case of	768
Therapeutic Use of	329, 398
Iron, Elimination of, after Injections	690
Injury from Continued Use	39
Jamaica Dogwood, Therapeutic Value of	171
Jequirity in Abscesses and Ulcers of Cornea	640
Jambul—a New Remedy for Diabetes	830
Kalrin, Tests for	254, 288
Kélar	402
Kellogg, J. H., Oxygen Enemata	589
Kemper, W. G., Therapeutic Indications in Different Temperaments	28
Kidney, Manipulation in Stone in the	472
Action of Drugs on Circulation and Secretion of	633
Kinesitherapy, A Lecture on	361, 433
Knee-Jerk, Will the, divide Typhoid Fever from Meningitis?	478

Marbotin, Peter J., Modern Antipyretics	289
Massage, Effects of, on Exhalation from Lungs and Skin	332
for Corneal Opacities	340
Lecture on	577
Substitute for	246
Maxillæ, Treatment of Fracture of	632
Mays, Thos. J., Non-Contagiousness of Pulmonary Tuberculosis	145
Chest Movements of the Indian Female	297
Median Nerve, Suture of, after Ten Weeks	248
Medication of Nerves	55
Melon-Root as an Emetic	556
Root as a Substitute for Ipecac	359
Menthol	342
in Tubercular Laryngitis, Use of	762
Mentholate	36
Mercurial Injections	576
Preparations, Diuretic Action of	392
Mercury, Bichloride of, in Diphtheria	45
Carbolate of, in Syphilis	408, 669
Chancroid successfully treated with	458
Treatment of Syphilis by	323
Yellow Oxide, Injections of, in Syphilis	186
Meteorology	174
Methyl Chloride in Neuralgic Affections	114
Methylal	51, 269, 316, 411, 833
Pharmacology and Therapeutics of	789
Methylene Chloride as an Anesthetic	819
Metric Table	141
Migraine, Treatment of, with a Domestic Remedy	408
Milk, Changes in, produced by Freezing	718
Digestion of	216
Drugs which affect Secretion of	122
in Scarlatina	50
Juices, Ferments in	268
New Test for	648
Mineral Springs of the United States	180
Mollin	469
Momordica Bucha	503
Morphine and Atropine, Antagonism between	615
Case of Intoxication from	194
in Diabetes	183
Pharmacology of some Bodies derived from	636
taking, Detection of	575
Morphinomania, Treatment of	432, 689
Mydriatics and Myotics, Influence of, upon Intraocular Tension	695
Myrtol	359
Mytilotoxine	71
Naphthalin	188
Formula for	576
in Pill Form	557
Naphthol in Enuresis	610
in Sweating of Extremities and Axilla	143
Nares, to Remove Foreign Bodies from Anterior	680
Nasal Cavity, Method of applying Fluids to	681
Treatment of Whooping-Cough	118, 763
Nerve-Suture	754
Nettle Juice	356
Neuralgia of Fifth Nerve	752
Neuritis, Experimental	501
New Remedies, Use of some	359, 502
Night-Sweats, New Remedy for	567, 646, 716
Nitrogenized Air, Antipyretic Action of	270
Nitro-Glycerin and the Nitrites, Chemistry of, etc.	641
Indications for the Use of	261
Poisonous Symptoms from	459
Uses of	769
Nitrous Oxide Gas, Physiological Action of	345
Noer, J., Poisonous Symptoms from Nitro-Glycerine	459
Nutrient Enemata	410
Obesity, Treatment of	670
Oleum Hyoscyami and other "Olea Cocta," Value of	716
Santalal Ostindicum as an Antilemnorrhagic	38
Opium, Administration of	557
Osler, William, Antifebrin	163
